“_To braise the inside_ (or _small fillet_, as it is called in France) _of a sirloin of beef_: Raise the fillet clean from the joint; and with a sharp knife strip off all the skin, leaving the surface of the meat as smooth as possible; have ready some strips of unsmoked bacon, half as thick as your little finger, roll them in a mixture of thyme finely minced, spices in powder, and a little pepper and salt. Lard the fillet quite through with these, and tie it round with tape in any shape you choose. Line the bottom of a stewpan (or braising-pan) with slices of bacon; next put in a layer of beef or veal, four onions, two bay-leaves, two carrots, and a bunch of sweet herbs, and place the fillet on them. Cover it with slices of bacon, put some trimmings of meat all round it, and pour on to it half a pint of good beef broth or gravy. Let it stew as gently as possible for two hours and a half; take it up, and keep it very hot; strain, and reduce the gravy by quick boiling until it is thick enough to glaze with; brush the meat over with it; put the rest in the dish with the fillet, after the tape has been removed from it, and send it directly to table.”

Equal parts of Madeira and gravy are sometimes used to moisten the meat.

No attempt should be made to braise a joint in any vessel that is not very nearly of its own size.

[Illustration:

Copper Stewpan.[74]]

Footnote 74:

The line which passes round this stewpan just above the handle, is a mistake of the designer, and conveys an erroneous idea of the form of the cover, and it ought to have been omitted.

A round of buttered paper is generally put over the more delicate kinds of braised meat, to prevent their being browned by the fire, which in France is sometimes put round the lid of the braising-pan, in a groove made on purpose to contain it. The embers of a wood fire mixed with the hot ashes, are best adapted to sustain the regular but gentle degree of heat required for this mode of cooking.

Braising pans are of various forms. They are often shaped like a ham-kettle, and sometimes like the design at the commencement of this section; but a stewpan of modern form, or any other vessel which will admit of embers being placed upon the lid, will answer for the purpose as well. Common cooks sometimes stew meat in a mixture of butter and water, and _call it braising._

LARDING.

[Illustration:

Larding Pins.]

Cut into slices, of the same length and thickness, some bacon of the finest quality; trim away the outsides, place the slices evenly upon each other, and with a sharp knife divide them obliquely into small strips of equal size. For pheasants, partridges, hares, fowls, and _fricandeaux_, the bacon should be about the eighth of an inch square, and two inches in length; but for meat which is to be larded quite through, instead of on the outside merely, the bits of bacon (properly called lardoons) must be at least the third of an inch square.

In general, the breasts only of birds are larded, the backs and thighs of hares, and the whole of the upper surface of a _fricandeau_: these should be thickly covered with small lardoons, placed at regular intervals, and in lines which intersect each other, so as to form rather minute diamonds.

The following directions for larding a pheasant will serve equally for poultry, or for other kinds of game:—

Secure one end of the bacon in a slight larding-needle, and on the point of this take up sufficient of the flesh of the bird to hold the lardoon firmly; draw the needle through it, and part of the bacon, of which the two ends should be left of equal length. Proceed thus, until the breast of the pheasant is entirely garnished with lardoons, when it ought to resemble in appearance a cake thickly stuck with strips of almonds.

The larger strips of bacon, after being rolled in a high seasoning of minced herbs and spices, are used to lard the _inside_ of meat, and they should be proportioned to its thickness, as they must be passed quite through it. For example: a four-inch slice from a rump of beef will require lardoons of very nearly that length, which must be drawn through with a large larding-pin, and left in it, with the ends just out of sight on either side.

In France, truffles, anchovies, slices of tongue, and of fat, all trimmed into proper shape, are occasionally used for larding. The bacon employed there for the purpose is cured without any saltpetre (as this would redden the white meats), and it is never smoked: the receipt for it will be found in Chapter XIII.

A turkey is sometimes larded with alternate lardoons of fat bacon and of bullock’s tongue, which has been pickled but not dried: we apprehend that the lean of a half-boiled ham, of good colour, would answer the purpose quite as well, or better.

Larding the surface of meat, poultry, or game, gives it a good appearance, but it is a more positive improvement to meat of a dry nature to interlard the inside with large lardoons of well-seasoned, delicate, striped English bacon.

BONING.

Very minute directions being given in other parts of our volume for this, we confine ourselves here to the following rules:—in disengaging the flesh from it, work the knife always _close to the bone_, and take every care not to pierce the outer skin.

TO BLANCH MEAT OR VEGETABLES.

This is merely to throw either into a pan of boiling water for a few minutes, which gives firmness to the first, and is necessary for some modes of preparing vegetables.

The breast only of a bird is sometimes held in the water while it boils, to render it firm for larding. To preserve the whiteness of meat, and the bright green of vegetables, they are lifted from the water after they have boiled a few minutes, and are thrown immediately into spring water, and left till cold.

5 to 10 minutes.

GLAZING

[Illustration]

This process we have explained at the article _Glaze_, Chapter IV. The surface of the meat should be covered evenly, with two or three separate layers of the glaze, which, if properly made, soon becomes firm. A ham should be well dried in the oven before it is laid on. Cutlets of all kinds may be glazed before they are sent to table, with very good effect. The figure above represents a glaze-pot and brush, used for heating and applying the preparation: a jar placed in a pan of boiling water may be substituted for the first, when it is not at hand.

TOASTING.

[Illustration]

A very cheap apparatus, by which chops can be dressed before a clear fire, is shown by the first of these figures; and the second is peculiarly convenient when bread or muffins are required to be toasted expeditiously and in large quantities, without much time and attention being bestowed upon them.

TO BROWN THE SURFACE OF A DISH WITHOUT BAKING OR PLACING IT AT THE FIRE.

This is done with a salamander, as it is called, formed like the engraving below; it is heated in the fire, and held over the dish sufficiently near to give it colour. It is very much used in a superior order of cookery. A kitchen shovel is sometimes substituted for it on an emergency.

[Illustration]

CHAPTER X.

=Beef.=

[Illustration]

No. 1. Sirloin. 2. Rump. 3. Edge-bone. 4. Buttock, or Round. 5. Mouse Buttock. 6. Veiny Piece. 7. Thick Flank. 8. Thin Flank. 9. Leg. 10. Fore Rib. (Five Ribs.) 11. Middle Rib. (Four Ribs.) 12. Chuck Rib. (Three Ribs.) 13. Shoulder, or Leg of Mutton Piece. 14. Brisket. 15. Clod. 16. Neck. 17. Shin. 18. Cheek.

TO CHOOSE BEEF.

Beef is in reality in season through the entire year, but it is best during the winter months, when it will hang a sufficient time to become tender before it is dressed. Meat of a more delicate nature is better adapted for the table in summer. The _Christmas beef_ of England is too much celebrated to require any mention here.

If young and freshly killed, the lean of ox-beef will be smoothly grained, and of a fine, healthy, carnation-red, the fat rather white than yellow, and the suet white and firm. Heifer-beef is more closely grained, and rather less bright of colour, the bones are considerably smaller, and the fat of a purer white.

Of bull-beef we only speak to warn our readers that it is of all meat the coarsest and the most rank in flavour. It may be known by its dark hue, its close tough fibre, and the scanty proportion, bad appearance, and strong odour of its fat.

In choice and well-fed beef, the lean will be found intergrained with fat: very lean meat is generally of an inferior quality.

The ribs, the sirloin, and the rump, are the proper joints for roasting. The round, or buttock, the edgebone, the second round, or mouse-buttock, the shin, the brisket, the shoulder or leg of mutton piece, and the clod, may be boiled or stewed. The neck is generally used for soup or gravy; and the thin flank for collaring. The best steaks are cut from the middle of the rump; the next best from the veiny piece, or from the chuck-rib. The inside of the sirloin, commonly used for the purpose in France, makes by far the most delicate steaks; but though _exceedingly_ tender, they are considered by some English epicures to be wanting in flavour.

The finest part of the sirloin is the chump-end, which contains the larger portion of the fillet; of the ribs, the middle ones are those generally preferred by experienced housekeepers.

TO ROAST SIRLOIN, OR RIBS OF BEEF.

Let the joint hang as long as it can possibly be kept perfectly sweet. When it is first brought in, remove the pipe of marrow which runs along the back-bone; and cut out the kernels from the fat. Be very careful in summer to guard it from flies; examine it frequently in warm or damp weather; and scrape off with a knife, or wipe away with a dry cloth, any moisture which may appear on the surface: when this has been done, dust some powdered ginger or pepper over it. Unless the joint should be very large, its appearance will be improved by taking off the ends of the bones, which may then be salted for a few days, and afterwards boiled. Spit the beef firmly; place it near the fire to render the surface firm, as directed in the article _Roasting_, of Chapter IX.; then draw it to a distance and let it remain so until the heat has well penetrated the interior; and, if from prejudice the old method be still preferred, heat it very gradually in the first instance (in either case baste it constantly), and let it be drawn nearer to the fire for the last half hour or more of roasting, merely to brown it well. Persons who object to meat being _frothed_ for table, have it dredged with flour when it is first placed at the fire, and sprinkled with fine salt when it is nearly done. It is not necessary to paper the fat of beef, as many cooks direct, if proper attention be given to it while roasting.

As a general rule, it may be observed, that when the steam from the meat draws strongly towards the fire, it is nearly or quite ready to serve. The time required to roast it will depend on the state of the weather,[75] the size and strength of the fire, the thickness of the joint, the use or non-use of a meat-screen or reflector, the general temperature of the kitchen, and other contingencies. A quarter of an hour for each pound of meat is commonly allowed for solid, heavy joints, and, if the directions we have given be attended to, this will not be found too much even for persons who prefer beef somewhat rare: it must be left longer at the fire if wished very thoroughly roasted, and quite double the usual time when the plan we have noticed at page 172, is adopted. When likely to be sent to table hashed, minced, or dressed a second time in any way, the juices of the meat should be dried up as little as possible when it is first cooked.

Footnote 75:

The meat will be much sooner done in hot weather than in cold. If frozen, it must be thawed _very gradually_ before it is put to the fire, or no length of time will roast it; this will be effected better by laying it into cold water for some hours before it is wanted, than by any other means.

ROAST RUMP OF BEEF.

As this joint is generally too much to serve whole, as much of it as will form a handsome dish should be cut from the chump end to roast. It must be managed as the sirloin, to which it is commonly preferred by connoisseurs. When boned and rolled into the form of a fillet of veal, as it sometimes is, nearly or quite an additional hour should be allowed to dress it.

TO ROAST PART OF A ROUND OF BEEF.

The natural division of the meat will show where the silver side of the round is to be separated from the upper or tongue side, which is the proper part for roasting, and which will be found equally good and profitable for the purpose, if allowed to hang as long as it can be kept sweet before it is dressed. Care should be taken in dividing the meat, not to pierce the inner skin. The silver side, with the udder, if there should be one to the joint, may be pickled, spiced, or simply salted, and will be excellent either way. The outside fat should be drawn tightly round the remainder of the beef, which must be firmly skewered, or bound with tape, to keep it in form. It will require long roasting at a strong, steady fire, and should be kept constantly basted.

Beef, 14 lbs.: 4-1/2 to 5 hours.

Obs.—We think that larding the beef quite through with large lardoons of firm fat, of udder, or of bacon, would be an improvement; and we ought also to observe, that unless it be delicate and of fine quality, it will not answer well for roasting.

TO ROAST A FILLET OF BEEF.

Raise the fillet from the inside of the sirloin, or from part of it, with a sharp knife; leave the fat on, trim off the skin, lard it through, or all over, or roast it quite plain; baste it with butter, and send it very hot to table, with tomata sauce, or _sauce piquante_, or eschalot

sauce, in a tureen. It is sometimes served with brown gravy and currant jelly; it should then be garnished with forcemeat-balls, made as for hare. If not very large, an hour and a quarter will roast it well with a brisk fire.

Obs.—The remainder of the joint may be boned, rolled, and roasted, or braised; or made into meat cakes; or served as a miniature round of beef.

1-1/4 hour.

ROAST BEEF STEAK.

If extremely tender, a large slice from the middle of the rump will make an excellent small dish of roast meat, when a joint is not easily to be procured. Let it be smoothly cut, from an inch to an inch and a half thick, flattened on a table, and the inside sprinkled with a little fine salt and cayenne, or common pepper. Make a roll of forcemeat, as No. 1, Chapter VIII., adding, at pleasure, a flavouring of minced onion or eschalot, and increasing the quantity of spices; place this on one end of the steak, and roll it up tightly in it; skewer and bind the meat so that the forcemeat cannot escape; fasten a buttered paper over it, and roast it an hour and a half, or more, according to its size. Twenty minutes before it is served, take off the paper and flour the meat, which should be kept well basted with butter all the time it is roasting. Send brown gravy to table with it, and pour a little over the beef.

1-1/2 hour, or more.

TO BROIL BEEF STEAKS.

The steaks should be from half to three quarters of an inch thick, equally sliced, and freshly cut from the middle of a well kept, finely grained, and tender rump of beef. They should be neatly trimmed, and once or twice divided, if very large. The fire, as we have already said in the general directions for broiling (page 175), must be strong and clear. The bars of the gridiron should be thin, and not very close together. When they are thoroughly heated, without being sufficiently burning to scorch the meat, wipe and rub them with fresh mutton suet; next pepper the steaks slightly, but never season them with salt before they are dressed; lay them on the gridiron, and when done on one side, turn them on the other, being careful to catch, in the dish in which they are to be sent to table, any gravy which may threaten to drain from them when they are moved. Let them be served the _instant_ they are taken from the fire; and have ready at the moment, dish, cover, and plates, as hot as they can be. From eight to ten minutes will be sufficient to broil steaks for the generality of eaters, and more than enough for those who like them but partially done.

Genuine amateurs seldom take prepared sauce or gravy with their steaks, as they consider the natural juices of the meat sufficient. When any accompaniment to them is desired, a small quantity of choice mushroom catsup may be warmed in the dish that is heated to receive them; and which, when the not very refined flavour of a raw eschalot is liked, as it is by some eaters, may previously be rubbed with one, of which the large end has been cut off. A thin slice or two of fresh butter is sometimes laid under the steaks, where it soon melts and mingles with the gravy which flows from them. The appropriate tureen sauces for broiled beef steaks are onion, tomata, oyster, eschalot, hot horseradish, and brown cucumber, or mushroom sauce.

Obs. 1.—We have departed a little in this receipt from our previous instructions for broiling, by recommending that the steaks should be turned but _once_, instead of “often,” as all great authorities on the subject direct. By trying each method, our readers will be able to decide for themselves upon the preferable one: we can only say, that we have never eaten steaks so excellent as those which have been dressed _exactly_ in accordance with the receipt we have just given, and we have taken infinite pains to ascertain the really best mode of preparing this very favourite English dish, which so constantly makes its appearance both carelessly cooked and ill served, especially at private tables.

Obs. 2.—It is a good plan to throw a few bits of charcoal on the fire some minutes before the steaks are laid down, as they give forth a strong heat without any smoke: a coke fire is also advantageous for broiling them.

The upright gridirons, by which meat is rather _toasted_ than broiled, though used in many kitchens, and generally pronounced exceedingly convenient where they have been tried, do not appear to as so well adapted for dressing steaks as those of less modern fashion, which are placed _over_, instead of before the fire.

BEEF STEAKS À LA FRANÇAISE.

The inside of the sirloin freed from skin and cut evenly into round quarter-inch slices, should properly be used for these; but when it cannot be obtained, part of the rump must be substituted for it. Season the steaks with fine salt and pepper, brush them with a little

clarified butter, and broil them over a clear brisk fire. Mix a teaspoonful of parsley minced extremely fine, with a large slice of fresh butter, a little cayenne, and a small quantity of salt. When the steaks are done, put the mixture into the dish intended for them, lay them upon it, and garnish them plentifully with fried potatoes. It is an improvement to squeeze the juice of half a lemon on the butter before the meat is heaped over it. The potatoes should be sliced rather thin, coloured of a fine brown, and placed evenly round the meat.

BEEF STEAKS À LA FRANÇAISE (ENTRÉE).

(_Another Receipt._)

Cut the beef into small thin steaks as above, season them with fine salt and pepper, dredge them lightly with flour, and fry them in butter over a brisk fire; arrange them in a chain round a very hot dish, and pour into the centre the olive sauce of Chapter V.

STEWED BEEF STEAK (ENTRÉE).

This may be cut from one to two inches thick, and the time of stewing it must be proportioned to its size. Dissolve a slice of butter in a large saucepan or stewpan, and brown the steak on both sides, moving it often that it may not burn; then shake in a little flour, and when it is coloured pour in by degrees rather more than sufficient broth or water to cover the meat. When it boils, season it with salt, take off the scum, slice in one onion, a carrot or two, and half a turnip; add a small bunch of sweet herbs, and stew the steak very softly from two hours and a half to three hours. A quarter of an hour before it is served, stir well into the gravy three teaspoonsful of rice flour smoothly mixed with a little cayenne, half a wineglassful of mushroom catsup, and a slight seasoning of spice. A teaspoonful of currie powder, in addition, will improve both the flavour and the appearance of the sauce. The onion is sometimes browned with the meat; and the quantity is considerably increased. Eschalots may be used instead, where their strong flavour is approved. A few button-mushrooms, stewed from twenty to thirty minutes with the meat, will render the catsup unnecessary. Wine, or any favourite store sauce, can be added at will.

2-1/2 to 3 hours.

FRIED BEEF STEAK.

We have little to add here to the directions of Chapter IX., which are sufficient to enable the cook to send a dish of fried steaks to table properly dressed. Currie sauce, highly _onioned_, is frequently served with them.

BEEF STEAK STEWED IN ITS OWN GRAVY.

(_Good and wholesome._)

Trim all the fat and skin from a rump steak of nearly an inch thick, and divide it once or twice; just dip it into cold water, let it drain for an instant, sprinkle it on both sides with pepper, and then flour it rather thickly; lay it quite flat into a well-tinned iron saucepan or stewpan, which has been rinsed with cold water, of which three or four tablespoonsful should be left in it. Place it over (not upon) a _very_ gentle fire, and keep it just simmering from an hour and a half to an hour and three quarters, when, if the meat be good, it will have become perfectly tender. Add salt to it when it first begins to boil, and turn it when rather more than half done. A couple of spoonsful of gravy, half as much catsup, and a slight seasoning of spice, would, to many tastes, improve this dish, of which, however, the great recommendation is its wholesome simplicity, which renders it suitable to the most delicate stomach. A thick mutton cutlet from the middle of the leg is excellent dressed thus.

1-1/2 to 1-3/4 hour.

BEEF OR MUTTON CAKE.

(_Very good._)

Chop two pounds of lean and very tender beef or mutton, with three quarters of a pound of beef suet; mix them well, and season them with a dessertspoonful of salt, nearly as much pounded cloves, a teaspoonful of pounded mace, and half a teaspoonful of cayenne. Line a round baking dish with thin slices of fat bacon, press the meat closely into it, smooth the top, and cover it with bacon, set a plate on it with a weight, and bake it two hours and a quarter. Take off the bacon, and serve the meat hot, with a little rich brown gravy, or set it by until cold, when it will be equally good. The fat of the meat which is used for this dish can be chopped

up with it instead of suet, where it is liked as well; and onion, or eschalot, shred fine, minced savoury herbs, grated lemon-peel, rasped bacon, or mushrooms cut small, may in turn be added to vary it in flavour.

Lean beef or mutton, 2 lbs.; suet, 3/4 lb.; salt and cloves in powder, each a dessertspoonful; mace, 1 teaspoonful; half as much cayenne: baked 2-1/4 hours.

Obs.—A larger portion of suet or of fat will render these cakes lighter, but will not otherwise improve them: they may be made of veal or of venison, but one-third of mutton suet or of fat bacon should be mixed with this last.

GERMAN STEW.

Cut into about three-inch squares, two pounds and a half of the leaner part of the veiny piece of beef, or of any joint which is likely to be tender, and set it on to stew, with rather less than a quart of cold broth or water, and one large onion sliced. When these begin to boil, add a teaspoonful of salt, and a third as much of pepper, and let them simmer gently for an hour and a half. Have ready some young white cabbages, parboiled; press the water well from them, lay them in with the beef, and let the whole stew for another hour. More onions, and a seasoning of mixed spices, or a few bits of lean bacon, or of ham, can be added to this stew when a higher flavour is desired; but it is very good without.

Beef, 2-1/2 lbs.; water, or broth, 1-3/4 pint; onion, 1; salt, 1 teaspoonful; third as much pepper: 1-1/2 hour. Parboiled cabbages, 3 or 4: 1 hour.

WELSH STEW.

Take the same proportions of beef, and of broth or water, as for the German Stew. When they have simmered gently for an hour, add the white part of from twenty to thirty leeks, or two dozens of button onions, and five or six young mild turnips, cut in slices, a small lump of white sugar, nearly half a teaspoonful of white pepper and more than twice as much salt. Stew the whole softly from an hour and a quarter to an hour and a half, after the vegetables are added.

Beef and water as above: 1 hour. Leeks, 20 to 30: or small onions, 24; young turnips, 6; small lump of sugar; white pepper, nearly 1/2 teaspoonful; salt, twice as much: 1-1/4 to 1-1/2 hour.

A GOOD ENGLISH STEW.

On three pounds of tender rump of beef, freed from skin and fat, and cut down into about two-inch squares, pour rather more than a quart of cold broth or gravy. When it boils add salt if required, and a little cayenne, and keep it just simmering for a couple of hours; then put to it the grated rind of a large lemon, or of two small ones, and half an hour after, stir to it a tablespoonful of rice-flour, smoothly mixed with a wineglassful of mushroom catsup, a dessertspoonful of lemon-juice, and a teaspoonful of soy: in fifteen minutes it will be ready to serve. A glass and a half of port, or of white wine, will greatly improve this stew, which may likewise be flavoured with the store-sauce of page 146, or with another, which we find excellent for the purpose, made with half a pint of port wine, the same of mushroom-catsup, a quarter pint of walnut pickle, a tablespoonful of the best soy, and a dessertspoonful of cayenne-vinegar, all well shaken together and poured into a bottle containing the thin rind of a lemon and two fine mellow anchovies, of moderate size. A few delicately fried forcemeat-balls may be slipped into it after it is dished.

Obs.—The limits of our work will not permit us to devote a further space to this class of dishes, but an intelligent cook will find it easy to vary them in numberless ways. Mushrooms, celery, carrots, sweet herbs, parboiled new potatoes, green peas, rice, and currie-powder may be advantageously used for that purpose. Ox-tails, just blanched and cut into joints, will be found excellent substitutes for the beef: mutton and veal also may be dressed in the same way. The meat and vegetables can be browned before broth or water is poured to them; but though, perhaps, more savoury, the stew will then be much less delicate. Each kind of vegetable should be allowed something more than sufficient time to render it perfectly tender, but not so much as would reduce it to pulp.

TO STEW SHIN OF BEEF.

Wash, and set it on to stew in sufficient cold water to keep it just covered until it is done. When it boils, take off the scum and put an ounce and a quarter of salt to the gallon of water. It is usual to add a few cloves and some black pepper, slightly bruised and tied up loosely in a fold of muslin, two or more onions, a root of celery, a bunch of savoury herbs, four or five carrots, and as many turnips,

either whole or sliced: if to be served with the meat, the two last will require a little more than the ordinary time of boiling, but otherwise they may be simmered with the meat from the beginning. Give the beef from four to five hours' gentle stewing; and serve it with part of its own liquor thickened and flavoured, or quite plain. An excellent dish for a family may be made by stewing the thick fleshy part of the shin or leg, in stock made of the knuckle, with a few bits of lean ham, or a slice of hung beef from which the smoked edges have been carefully pared away, and some spice, salt, and vegetables: by frying these last before they are thrown into the soup-pot the savour of the stew will be greatly heightened; and a tureen of good soup may be made of its remains, after it has been served at table.

Ox-cheek, after having been soaked for four or five hours, and washed with great nicety, may be dressed like the shin; but as it has little flavour, the gravy should be strained, and quite cleared from fat, then put into a clean saucepan, and thickened as soon as it boils, with the following mixture:—three dessertspoonsful of rice-flour, nearly a wineglassful of catsup, a teaspoonsful of currie-powder, or a little powdered ginger and cayenne. When these have stewed for ten minutes, dish the head, pour the sauce over, and serve it.

Shin of beef, 4 to 5 hours. Ox-cheek, 2 to 3 hours.

FRENCH BEEF À LA MODE.

(_A common Receipt._)

Take seven or eight pounds of a rump of beef (or of any other tender joint), free from bone, and skewer it firmly into a good shape. Put two ounces of butter into a thick saucepan or stewpan, and when it boils stir to it a tablespoonful of flour; keep these well shaken over a gentle fire until they are of a fine amber colour; then lay in the beef, and brown it on both sides, taking care that it shall not stick to the pan. Pour to it by slow degrees, letting each portion boil before the next is added or the butter will float upon the surface and be difficult to clear off afterwards, three quarters of a pint of hot water or gravy; add a bunch of savoury herbs, one large or two small carrots cut in thick slices, two or three moderate-sized onions, two bay-leaves, and sufficient pepper and salt to season the gravy. Let the meat simmer gently from four to five hours, and turn it when it is half done. When ready to serve, lift the beef into a hot dish, lay the vegetables round, and pour the gravy over it, after having taken out the herbs and skimmed away the fat. In France, half or the whole of a calf's foot is stewed with the beef, which is there generally larded with thick lardoons of fat bacon. (For larding, see Chapter X.) Veal dressed in this way is even better than beef. The stewpan used for either should be as nearly of the size of the meat as possible.

Beef, 7 to 8 lbs.: 4 to 5 hours.

STEWED SIRLOIN OF BEEF.

As a matter of convenience we have occasionally had this joint stewed instead of roasted, and have found it excellent. Cut out the inside or fillet as entire as possible, and reserve it for a separate dish; then remove the bones with care, or let the butcher do this. Spread the meat flat on a table and cover the inside with thin slices of striped bacon, after having first strewed over it a mixed seasoning of a small teaspoonful of salt, half as much mace or nutmeg, and a moderate quantity of pepper or cayenne. Roll and bind the meat up firmly, lay it into a stewpan or thick iron saucepan nearly of its size, and add the bones and as much good beef broth as will nearly cover the joint. Should this not be at hand, put a few slices of lean ham or bacon under the beef, and lay round it three pounds of neck or knuckle of veal, or of stewing beef divided into several parts; then pour to it cold water instead of broth. In either case, so soon as it has boiled a few minutes and been well cleaned from scum, throw in a large faggot of savoury herbs, three or four carrots, as many leeks, or a large onion stuck with a dozen cloves; and an hour later two blades of mace, and half a teaspoonful of peppercorns. Stew the beef _very_ gently indeed from four to five hours, and longer, should the joint be large: serve it with a good _Espagnole sauce piquante_, or brown caper sauce. Add what salt may be needed before the vegetables are thrown in; and, after the meat is lifted out, boil down to soup or gravy the liquor in which it has been stewed. To many tastes it would be an improvement to flour and brown the outside of the beef in butter before the broth or water is poured to it: it may also be stewed (but somewhat longer) half-covered with rich gravy, and turned when partially done. Minced eschalots may be strewed over the inside before it is rolled, when their strong savour is relished, or veal forcemeat may supply their place.

TO STEW A RUMP OF BEEF.

This joint is more easily carved, and is of better appearance when the bones are removed before it is dressed. Roll and bind it firmly with a fillet of tape, cover it with strong cold beef broth or gravy, and stew it very gently indeed from six hours to between seven and eight; add to it, after the scum has been well cleared off, one large or two moderate-sized onions stuck with thirty cloves, a head of celery, two carrots, two turnips, and a large faggot of savoury herbs. When the beef is perfectly tender quite through, which may be known by probing it with a sharp thin skewer, remove the fillets of tape, dish it neatly, and serve it with a rich _Espagnole_, and a garnish of forced tomatas, or with a highly-flavoured brown English gravy, and stewed carrots in the dish: for these last the mild preparation of garlic or eschalots, of page 122, may be substituted with good effect. They should be well drained, laid round the meat, and a little brown gravy should be poured over the whole.

This is the most simple and economical manner of stewing the beef; but should a richer one be desired, half roast the joint, and stew it afterwards in strong gravy to which a pint of mushrooms, and a pint of sherry or Madeira, should be added an hour before it is ready for table. Keep it hot while a portion of the gravy is thickened with a well-made brown roux (see Chapter IV.), and seasoned with salt, cayenne, and any other spice it may require. Garnish it with large balls of forcemeat highly seasoned with minced eschalots, rolled in egg and bread-crumbs, and fried a fine golden brown.

Plainly stewed from 6 to 7 or 8 hours. Or: half roasted then stewed from 4 to 5 hours.

Obs.—Grated horseradish, mixed with some well-thickened brown gravy, a teaspoonful of mustard, and a little lemon-juice or vinegar, is a good sauce for stewed beef.

BEEF PALATES. (ENTRÉE.)

First rub them well with salt, to cleanse them well; then wash them thoroughly in several waters, and leave them to soak for half an hour before they are dressed. Set them over the fire in cold water, and boil them gently until the skin will peel off, and the palates are tolerably tender. It is difficult to state the exact time required for this, as some will be done in two hours and a half, and others in not less than from four to five hours. When thus prepared, the palates may be cut into various forms, and simmered until fit to serve in rich brown gravy, highly flavoured with ham, cayenne, wine, and lemon-peel; or they will make an excellent currie. As they are very insipid of themselves, they require a sauce of some piquancy, in which, after they have been peeled and trimmed, they should be stewed from twenty to thirty minutes, or until they are perfectly tender. The black parts of them must be cut away, when the skin is taken off. An onion, stuck with a few cloves, a carrot sliced, a teaspoonful of whole white pepper, a slice of butter, and a teaspoonful of salt, may be boiled with the palates in the first instance; and they will be found very good, if sent to table in the curried gravy of Chapter XVI., or in the Soubise of Chapter VI., made thinner than the receipts direct.

Boiled from 2-1/2 to 4 or 5 hours. Stewed from 20 to 30 minutes.

Obs.—A French cook of some celebrity, orders the palates to be laid on the gridiron until the skin can be easily peeled or scraped off; the plan seems a good one, but we have not tried it.

BEEF PALATES.

(_Neapolitan Mode._)

Boil the palates until the skin can be easily removed, then stew them very tender in good veal broth, lay them on a drainer and let them cool; cut them across obliquely into strips of about a quarter-inch in width, and finish them by either of the receipts for dressing maccaroni, which will be found in Chapters XVIII. and XX.

STEWED OX-TAILS.

They should be sent from the butcher ready jointed. Soak and wash them well, cut them into joints or into lengths of two or three joints, and cover them with cold broth or water. As soon as they boil remove the scum, and add a half-teaspoonful of salt or as much more as may be needed, and a little common pepper or cayenne, an onion stuck with half a dozen cloves, two or three small carrots, and a branch or two of parsley. When these have simmered for two hours and a quarter, try the meat with a fork, and should it not be perfectly tender, let it remain over the fire until it is so. Ox-tails sometimes require nearly or quite three hours' stewing: they may be served with the vegetables, or with the gravy strained from them, and thickened like the English stew of the present chapter.

Ox-tails, 2; water or broth to cover them; salt, 1/2 teaspoonful, or more; little pepper or cayenne; onion, 1; cloves, 6; carrots, 2 or 3; parsley, 2 or 3 branches: 2-1/2 to 3 hours.

BROILED OX-TAIL. (ENTRÉE.)

(_Very good._)

When the ox-tail is ready for the stewpan, throw it into plenty of boiling water slightly salted, and simmer it for fifteen minutes; then take it up and put it into fresh water to cool; wipe it, and lay it round in a small stewpan without dividing it, just cover it with good beef gravy, and stew it gently until very tender; drain it a little, sprinkle over it a small quantity of salt and cayenne, dip it into clarified butter and then into some fine bread-crumbs, with which it should be thickly covered, lay it on the gridiron, and when equally browned all over serve it immediately. If more convenient the ox-tail may be set into the oven or before the fire, until properly coloured: it may likewise be sent to table without broiling, dished upon stewed cabbage or in its own gravy thickened, and with tomata sauce, in a tureen.

TO SALT AND PICKLE BEEF, IN VARIOUS WAYS.

Let the meat hang a couple of days in mild weather, and four or five in winter, before it is salted or pickled. During the heat of summer it is better to immerse it entirely in brine, that it may be secured alike from the flies, and from the danger of becoming putrid. Trim it, and take out the kernels from the fat; then rub a little fine dry salt over it, and leave it until the following day; drain it well from the blood, which will be found to have flowed from it, and it will be ready for any of the following modes of curing, which are all excellent of their kind, and have been well proved.

In very cold weather, the salt may be applied quite warm to the meat: it should always be perfectly dry, and reduced to powder.

Saltpetre hardens and renders the meat indigestible; sugar, on the contrary, mellows and improves it much; and it is more tender when cured with bay salt than when common salt is used for it.

TO SALT AND BOIL A ROUND OF BEEF.

Mix an ounce of saltpetre, finely powdered, with half a pound of very coarse sugar, and rub the beef thoroughly with them; in two days add three quarters of a pound of common salt, well dried and beaten; turn and rub the meat well in every part with the pickle for three weeks, when it will be fit to dress. Just wash off the salt, and skewer the beef as round and as even as possible; bind it tightly with broad tape, cover it with cold water, place it over a rather brisk fire, and after it boils draw it to the side of the stove and let it simmer gently for at least five hours. Carrots, mashed turnips, or cabbages, are usually served with boiled beef; and horseradish stewed for ten minutes in equal parts of vinegar and water, then pressed well from them, and mixed with some rich melted butter, is a good sauce for it.

Beef, 20 lbs.; coarse sugar, 1/2 lb.; saltpetre, 1 oz.: 2 days. Salt, 3/4 lb.: 21 days. Boil 5 hours, or more.

Obs.—Beef cured by this receipt if properly boiled, is tender, of good colour and flavour, and not over salt. The rump, edgebone, and brisket may be salted, or pickled in the same way as the round.

HAMBURGH PICKLE FOR BEEF, HAMS, AND TONGUE.

Boil together, for twenty minutes, two gallons of water, three pounds of bay salt, two pounds of coarse sugar, two ounces of saltpetre, and two of black pepper, bruised, and tied in a fold of muslin; clear off the scum thoroughly, as it rises, pour the pickle into a deep earthen pan, and when it is quite cold lay in the meat, of which every part must be perfectly covered with it. A moderate-sized round of beef will be ready for table in a fortnight; it should be turned occasionally in the brine. Five pounds of common salt may be substituted for the quantity of bay salt given above; but the meat will not be so finely flavoured.

Water, 2 gallons; bay-salt, 3 lbs.; saltpetre, 2 oz.; black pepper, 2 oz.; sugar, 2 lbs.: 20 minutes.

ANOTHER PICKLE FOR TONGUES, BEEF, AND HAMS.

To three gallons of spring water add six pounds of common salt, two pounds of bay-salt, two pounds of common loaf sugar, and two ounces of saltpetre. Boil these over a gentle fire, and be careful to take off all the scum as it rises: when quite cold it will be fit

for use. Rub the meat to be cured, with fine salt, and let it drain for a day in order to free it from the blood; then immerse it in the brine, taking care that every part of it shall be covered. Young pork should not remain more than from three to five days in the pickle; but hams for drying may be left in it for a fortnight at least; tongues will be ready in rather less time. Beef may remain from one week to two, according to its size, and the degree of saltness desired for it. A little experience will soon teach the exact time required for the different kinds of meat. When the pickle has been in use for about three months, boil it up again gently, and take the scum carefully off. Add to it three pounds of common salt, four ounces of sugar, and one of saltpetre: it will remain good for many months.

Water, 3 gallons; common salt, 6 lbs.; bay salt, 2 lbs.; loaf sugar, 2 lbs.; saltpetre, 2 oz.: boil 20 to 30 minutes.

DUTCH, OR HUNG BEEF.

For fourteen pounds weight of the round, the rump, or the thick flank of beef, mix two ounces of saltpetre with the same quantity of coarse sugar; rub the meat with them in every part, and let it remain for two days, then add one pound of bay salt, four ounces of common salt, and one ounce of ground black pepper. Rub these ingredients thoroughly into the beef, and in four days pour over it a pound of treacle; rub and turn it daily for a fortnight; drain, and send it to be smoked. When wanted for table, put it into plenty of boiling water, boil it slowly, and press it under a heavy weight while hot. A slice of this beef, from which the edges have been carefully trimmed, will serve to flavour soups or gravies as well as ham.

Beef, 14 lbs.; saltpetre and coarse sugar, each 2 oz.: 2 days. Bay salt, 1 lb.; common salt, 4 oz.: pepper, 1 oz.: 4 days. Treacle, 1 lb.: 14 days.

Obs.—Three quarters of a pound of coarse sugar may be rubbed into the meat at first, and the treacle may be altogether omitted; cloves and mace, too, may be added in the same proportion as for spiced beef.

COLLARED BEEF.

Only the thinnest part of the flank, or the ribs, which are not so generally used for it, will serve conveniently for collaring. The first of these should be hung in a damp place for a day or two, to soften the outer skin; then rubbed with coarse sugar, and left for a couple of days; when, for eight pounds of the meat, one ounce of saltpetre and half a pound of salt should be added. In ten days it will be fit to dress. The bones and tough inner skin must be removed, and the beef sprinkled thickly on the under side with parsley and other savoury herbs shred small, before it is rolled, which should be done very tightly: it must then be secured with a cloth, and bound as closely as possible with broad tape. It will require nearly or quite five hours of gentle boiling, and should be placed while hot under a weight, or in a press, without having the tape and cloth removed.

Beef, 8 lbs.; sugar, 3 oz.; salt, 8 oz.: 10 days. Boil 5 hours.

COLLARED BEEF.

(_Another way._)

Mix half an ounce of saltpetre with the same quantity of pepper, four ounces of bay salt, and four of common salt; with these rub well from six to seven pounds of the thin flank, and in four days add seven ounces of treacle; turn the beef daily in the pickle for a week or more; dip it into water, bone it and skin the inside, roll and bind it up very tightly, lay it into cold water, and boil it for three hours and a half. We have found beef dressed by this receipt extremely good: herbs can, of course, be added to it as usual. Spices and juniper berries would to many tastes improve it, but we give the receipt simply as we have been accustomed to have it used.

Thin flank, 6 to 7 lbs.; bay salt, and common salt, each 4 oz.; saltpetre, 1/2 oz.; pepper, 1/2 oz.: 4 days. Treacle, 7 oz.: 8 to 10 days. Boiled 3-1/2 hours.

A COMMON RECEIPT FOR SALTING BEEF.

One ounce of saltpetre, and a pound of common salt, will be sufficient for sixteen pounds of beef. Both should be well dried, and finely powdered; the saltpetre rubbed first equally over the meat, and the salt next applied in every part. It should be rubbed thoroughly with the pickle and turned daily, from a week to ten days. An ounce or two of sugar mixed with the saltpetre will render the beef more tender and palatable.

Beef, 16 lbs.; saltpetre, 1 oz.; salt, 1 lb.: 7 to 10 days.

SPICED ROUND OF BEEF.

(_Very highly flavoured._)

Rub the beef well in every part with half a pound of coarse brown sugar, and let it remain two days; then reduce to powder, and mix thoroughly before they are applied to the meat, two ounces of saltpetre, three quarters of a pound of common salt, a quarter of a pound of black pepper, three ounces of allspice, and four of bruised juniper-berries. Rub these ingredients strongly and equally over the joint, and do so daily for three weeks, turning it at the same time. Just wash off the spice, and put the beef into a tin, or covered earthen pan as nearly of its size as possible, with a cup of water or gravy; cover the top thickly with chopped beef-suet, and lay a coarse thick crust over the pan; place the cover on it, and bake the meat from five to six hours in a moderate oven, which should not, however, be sufficiently fierce to harden the outside of the joint, which, if properly managed will be exceedingly tender. Let it cool in the pan; and clear off the suet before it is dished. It is to be served cold, and will remain good for a fortnight.

Beef, 20 to 25 lbs. weight; sugar, 3 oz.: 2 days. Saltpetre, 2 oz.; common salt, 3/4 lb.; black pepper, 4 oz.; allspice, 3 oz.; juniper-berries, 4 oz.: 21 days. Baked 5 to 6 hours.

Obs.—We have not ourselves tested this receipt, but the meat cured by it has received such high commendation from several of our friends who have partaken of it frequently, that we think we may safely insert it without. The proportion of allspice appears to us more than would be agreeable to many tastes, and we would rather recommend that part of it should be omitted, and that a portion of nutmeg, mace, and cloves, should be substituted for it; as we have found these spices to answer well in the following receipt.

SPICED BEEF.

(_Good and wholesome._)

For twelve pounds of the round, rump, or thick flank of beef, take a large teaspoonful of freshly-pounded mace, and of ground black pepper, twice as much of cloves, one small nutmeg, and a quarter of a teaspoonful of cayenne, all in the finest powder. Mix them well with seven ounces of brown sugar, rub the beef with them and let it lie three days; add to it then half a pound of fine salt, and rub and turn it once in twenty-four hours for twelve days. Just wash, but do not soak it; skewer, or bind it into good form, put it into a stewpan or saucepan nearly of its size, pour to it a pint and a half of good beef broth, and when it begins to boil, take off the scum, and throw in one small onion, a moderate-sized faggot of thyme and parsley, and two large, or four small carrots. Let it simmer quite softly for four hours and a half, and if not wanted to serve hot, leave it in its own liquor until it is nearly cold. This is an excellent and far more wholesome dish than the hard, bright-coloured beef which is cured with large quantities of salt and saltpetre: two or three ounces of juniper-berries may be added to it with the spice, to heighten its flavour.

Beef, 12 lbs.; sugar, 7 oz.; mace and black pepper, each, 1 large teaspoonful; cloves, in powder, 1 large dessertspoonful; nutmeg, 1; cayenne, 1/4 teaspoonful: 3 days. Fine salt, 1/2 lb.: 12 days. Beef broth (or bouillon), 1-1/2 pint; onion, 1 small; bunch of herbs; carrots, 2 large, or 4 small: stewed 4-1/2 hours.

Obs.—We give this receipt _exactly_ as we have often had it used, but celery and turnips might be added to the gravy; and when the appearance of the meat is much considered, three-quarters of an ounce of saltpetre may be mixed with the spices; the beef may also be plainly boiled in water only, with a few vegetables, or baked in a deep pan with a little gravy. No meat must ever be left to cool in the stewpan or saucepan in which it is cooked; it must be lifted into a pan of its own depth, and the liquor poured upon it.

A MINIATURE ROUND OF BEEF.

“Select a fine rib of beef, and have it cut small or large in width according to your taste; it may thus be made to weigh from five to twelve pounds, or more. Take out the bone, and wrap the meat round like a fillet of veal, securing it with two or three wooden skewers; place it in a strong pickle for four or five days, and then cook it, taking care that it does not boil, but only simmers, from forty minutes, or more, according to its size. It is best to put it on in hot water, as it will not draw the gravy so much as cold. Many persons adjust a rib of beef in this way for roasting: let them try it salted, and they need not envy the possessor of the finest round of beef.” We give the receipt to our readers in its original form, and we can assure them, from our own experience, that it is a good one; but we would recommend that, in dressing the meat, quite the usual time for each pound of it should be allowed. When boned and rolled at the butcher’s, the skewers should be removed when it is first brought in; it should be well wiped with a dry cloth, or

washed with a little fresh brine, and a small quantity of salt and saltpetre should be rubbed over the inside, it may then be firmly bound with tape, and will be quite ready to boil when taken from the pickle. The sirloin, after the inside fillet is removed, may be cured and dressed in the same way, and will be found super-excellent if the beef be well fatted and properly kept. The Hamburgh pickle (see page 197) is perhaps the best for these joints. Part of the rump, taken clear of bone, answers admirably when prepared by this receipt.

BEEF ROLL, OR CANELLON DE BŒUF. (ENTRÉE.)

Chop and mix thoroughly two pounds of lean and very tender beef with one pound of slightly striped bacon; season them with a large teaspoonful of pepper, a little salt, a small nutmeg, or two-thirds as much mace, the grated rind of a lemon, or a teaspoonful of thyme and parsley finely minced. Form the whole into a thick rouleau, wrap a buttered paper round it, enclose it in a paste made of flour and water, and send it to a moderate oven for a couple of hours. Remove the paper and the crust, and serve the meat with a little brown gravy. Lamb and veal are excellent dressed in this way, particularly when mixed with plenty of mushrooms. Brown cucumber sauce should be served with the lamb; and currie, or oyster sauce, when there are no mushrooms, with the veal. A flavouring of onion or of eschalot, where it is liked, can be added at pleasure to the beef: suet, or the fat of the meat, may be substituted for the bacon.

Beef, 2 lbs.; bacon, 1 lb.; pepper, 1/4 oz.; little salt; small nutmeg; rind of 1 lemon, or savoury herbs, 1 tablespoonful: baked 2 hours.

MINCED COLLOPS AU NATUREL.

Mince finely a pound of very tender rump steak, free from fat or skin; season it with a moderate quantity of pepper and salt, set it over a gentle fire, and keep it stirred with a fork until it is quite hot that it may not gather into lumps. Simmer it very slowly in its own gravy from ten to twelve minutes, and then, should it be too dry, add a little boiling water, broth, or gravy; stew it for two minutes longer, and serve it directly.

These collops are particularly suited to persons in delicate health, or of weak digestion; and when an extra dish is required at a short notice, from the expedition with which they may be dressed, they are a convenient resource.

10 to 12 minutes.

SAVOURY MINCED COLLOPS.

Make a little thickening (see Brown _Roux_, Chapter V.) with about an ounce and a half of butter, and a dessertspoonful of flour; when it begins to be coloured, shake lightly into it a large teaspoonful of finely-shred parsley or mixed savoury herbs, two-thirds as much of salt, and half the quantity of pepper. Keep these stirred over a gentle fire until the thickening is of a deep yellow brown; then add a pound of rump-steak, finely minced, and keep it well separated with a fork until it is quite hot; next pour to it gradually half a cupful of boiling water, and stew the collops very gently for ten minutes. Before they are served, stir to them a little catsup, chili vinegar or lemon-juice: a small quantity of minced onion, eschalot, or a _particle_ of garlic, may be added at first to the thickening when the flavour is not objected to.

A RICHER VARIETY OF MINCED COLLOPS.

Omit the minced herbs from the thickening, and season it with cayenne and a small quarter of a teaspoonful of pounded mace. Substitute beef gravy for the boiling water, and when the collops are nearly done, fill a wineglass with one fourth of mushroom catsup, and three of port wine, and stir these to the meat. Serve the collops very hot, and garnish them with alternate forcemeat balls (see No. 1, Chapter VIII.) and fried sippets. If flavoured with a little gravy made from the bones of a roast hare, and served with currant jelly, these collops will scarcely be distinguished from game.

SCOTCH MINCED COLLOPS.

“Chop the beef small, season it with salt and pepper, put it, in its raw state, into small jars, and pour on the top some clarified butter. When wanted for use put the clarified butter into a frying-pan, and slice some onions into the pan and fry them. Add a little water to them, and put in the minced meat. Stew it well, and in a few minutes it will be fit to serve.”

BEEF TONGUES.

These may be cured by any of the receipts which we have already given for pickling beef, or for those which will be found further on for hams and bacon. Some persons prefer them cured with salt and saltpetre only, and dried naturally in a cool and airy room. For such of our readers as like them highly and richly flavoured we give our own method of having them prepared, which is this:—“Rub over the tongue a handful of fine salt, and let it drain until the following day; then, should it weigh from seven to eight pounds, mix thoroughly an ounce of saltpetre, two ounces of the coarsest sugar, and half an ounce of black pepper; when the tongue has been well rubbed with these, add three ounces of bruised juniper-berries; and when it has laid two days, eight ounces of bay salt, dried and pounded; at the end of three days more, pour on it half a pound of treacle, and let it remain in the pickle a fortnight after this; then hang it to drain, fold it in brown paper, and send it to be smoked over a wood fire for two or three weeks. Should the peculiar flavour of the juniper-berries prevail too much, or be disapproved, they may be in part, or altogether, omitted; and six ounces of sugar may be rubbed into the tongue in the first instance when it is liked better than treacle.”

Tongue, 7 to 8 lbs.; saltpetre, 1 oz.; black pepper, 1/2 oz.; sugar, 2 oz.; juniper-berries, 3 oz.: 2 days. Bay salt, 8 oz.: 3 days. Treacle, 1/2 lb.: 14 days.

Obs.—Before the tongue is salted, the root end, which has an unsightly appearance, should be trimmed away: it is indeed usual to take it off entirely, but some families prefer part of it left on for the sake of the fat.

BEEF TONGUES.

(_A Suffolk Receipt._)

For each very large tongue, mix with half a pound of salt two ounces of saltpetre and three quarters of a pound of the coarsest sugar; rub the tongues daily, and turn them in the pickle for five weeks, when they will be fit to be dressed, or to be smoked.

1 large tongue; salt, 1/2 lb.; sugar, 3/4 lb.; saltpetre, 2 oz.: 5 weeks.

TO DRESS BEEF TONGUES.

When taken fresh from the pickle they require no soaking, unless they should have remained in it much beyond the usual time, or have been cured with a more than common proportion of salt; but when they have been smoked and highly dried, they should be laid for two or three hours into cold, and as much longer into tepid water, before they are dressed: if extremely dry, ten or twelve hours must be allowed to soften them, and they should always be brought very slowly to boil. Two or three carrots and a large bunch of savoury herbs, added after the scum is cleared off, will improve them. They should be simmered until they are extremely tender, when the skin will peel from them easily. A highly dried tongue of moderate size will usually require from three and a half to four hours’ boiling; an unsmoked one about an hour less; and for one which has not been salted at all a shorter time will suffice.

BORDYKE RECEIPT FOR STEWING A TONGUE.

After the tongue has been soaked, trimmed, and washed with extreme nicety, lay it into a vessel of fitting size, and place round it three or four pounds of the neck, or of any other lean cuttings of beef, with some bones of undressed veal, and pour in sufficient cold water to keep it covered until it is done; or, instead of this, use strong unseasoned beef broth made with the shin, and any odd bits or bones of veal which may be at hand. Let the tongue be brought to boil very gradually, that it may be plump and tender. Remove the scum when it first rises, and when it is quite cleared off add a large faggot of parsley, thyme, and winter savoury, three carrots, a small onion, and one mild turnip. After three hours and a half of gentle simmering, probe the tongue, and if sufficiently done peel off the skin and serve it quickly. If not wanted hot for table, lay it upon a very clean board or trencher, and fasten it down to it by passing a carving fork through the root, and a smaller one through the tip, drawing the tongue straight with the latter before it is fixed in the board; let it remain thus until it is quite cold. It is much the fashion at present to glaze hams and tongues, but this should never be attempted by a cook not well acquainted with the manner of doing it, and the proper flavour and appearance of the glaze. For directions to make it, see page 104. Where expense is not regarded, three or four pounds of veal may be added to the beef in this receipt, or the tongue may be stewed in a prepared gravy made with equal parts of beef and veal, and vegetables as above, but without salt: this may afterwards be converted into excellent soup. A fresh or an unsmoked tongue may be dressed in this way, but will require less time: for the former, salt must be added to the gravy.

TO ROAST A BEEF HEART.

Wash and soak the heart very thoroughly, cut away the lobes, fill the cavities with a veal forcemeat (No. 1, Chapter VIII.), secure it well with a needle and twine, or very coarse thread, and roast it at a good fire for an hour and a half, keeping it basted plentifully with butter. Pour melted butter over it, after it is dished, and send it to table as hot as possible. Many persons boil the heart for three quarters of an hour before it is put to the fire, and this is said to render it more delicate eating; the time of roasting must of course be proportionately diminished. Good brown gravy may be substituted for the melted butter, and currant jelly also may be served with it.

1-1/2 hour, or more.

BEEF KIDNEY.

Slice the kidney rather thin, after having stripped off the skin and removed the fat; season it with pepper, salt, and grated nutmeg, and sprinkle over it plenty of minced parsley, or equal parts of parsley and eschalots chopped very small. Fry the slices over a brisk fire, and when nicely browned on both sides, stir amongst them a teaspoonful of flour, and pour in by degrees a cup of gravy and a glass of white wine; bring the sauce to the point of boiling, add a morsel of fresh butter and a tablespoonful of lemon-juice, and pour the whole into a hot dish garnished with fried bread. This is a French receipt, and a very excellent one.

BEEF KIDNEY.

(_A plainer way._)

Trim, and cut the kidney into slices; season them with salt and pepper, and dredge them well with flour; fry them on both sides, and when they are done through lift them out, empty the pan, and make gravy for them with a small slice of butter, a dessertspoonful of flour, pepper and salt, and a cup of boiling water; shake these round and give them a minute's simmering: add a little mushroom catsup, lemon juice, eschalot vinegar, or any store sauce that will give a good flavour. Minced herbs are to many tastes an improvement to this dish, to which a small quantity of onion shred fine can be added when it is liked.

6 to 9 minutes.

AN EXCELLENT HASH OF COLD BEEF.

Put a slice of butter into a thick saucepan, and when it boils throw in a dessertspoonful of minced herbs, and an onion (or two or three eschalots) shred small: shake them over the fire until they are lightly browned, then stir in a tablespoonful of flour, a little cayenne, some mace or nutmeg, and half a teaspoonful of salt. When the whole is well coloured, pour to it three-quarters of a pint or more of broth or gravy, according to the quantity of meat to be served in it. Let this boil gently for fifteen minutes; then strain it, add half a wineglassful of mushroom or of compound catsup, lay in the meat, and keep it by the side of the fire until it is heated through and is on the point of simmering, but be sure not to let it boil. Serve it up in a very hot dish, and garnish it with fried or toasted sippets of bread.

A COMMON HASH OF COLD BEEF OR MUTTON.

Take the meat from the bones, slice it small, trim off the brown edges, and stew down the trimmings with the bones well broken, an onion, a bunch of thyme and parsley, a carrot cut into thick slices, a few peppercorns, four cloves, some salt, and a pint and a half of water. When this is reduced to little more than three quarters of a pint, strain it, clear it from the fat, thicken it with a large dessertspoonful of rice flour, or rather less of arrow-root, add salt and pepper if needed, boil the whole for a few minutes, then lay in the meat and heat it well. Boiled potatoes are sometimes sliced hot into a very common hash.

Obs.—The cook should be reminded that if the meat in a hash or mince be allowed to boil, it will immediately become hard, and can then only be rendered eatable by very _long stewing_, which is by no means desirable for meat which is already sufficiently cooked.

BRESLAW OF BEEF.

(_Good._)

Trim the brown edges from half a pound of undressed roast beef, shred it small, and mix it with four ounces of fine bread-crumbs, a teaspoonful of minced parley, and two-thirds as much of thyme, two ounces of butter broken small, half a cupful of gravy or cream, a high seasoning of pepper and cayenne and mace or nutmeg, a small teaspoonful of salt, and three large eggs well whisked. Melt

a little butter in a deep dish, pour in the beef, and bake it half an hour; turn it out, and send it to table with brown gravy in a tureen. When cream or gravy is not at hand, an additional egg or two and rather more butter must be used. We think that grated lemon-rind improves the breslaw. A portion of fat from the joint can be added where it is liked. The mixture is sometimes baked in buttered cups.

Beef, 1/2 lb.; bread-crumbs, 4 oz.; butter, 2 oz.; gravy or cream, 1/2 cupful; parsley, 1 teaspoonful; thyme, two-thirds of teaspoonful; eggs, 3 or 4, if small; salt, 1 teaspoonful; pepper and nutmeg, 1/2 teaspoonful each: bake 1/2 hour.

NORMAN HASH.

Peel and fry two dozens of button onions in butter until they are lightly browned, then stir to them a tablespoonful of flour, and when the whole is of a deep amber shade, pour in a wineglassful and a half of red wine, and a large cup of boiling broth or water; add a seasoning of salt and common pepper or cayenne, and a little lemon-pickle catsup or lemon-juice, and boil the whole until the onions are quite tender; cut and trim into small handsome slices the remains of either a roast or boiled joint of beef, and arrange them in a clean saucepan; pour the gravy and onions on them, and let them stand for awhile to imbibe the flavour of the sauce; then place the hash near the fire, and when it is thoroughly hot serve it immediately, without allowing it to boil.

FRENCH RECEIPT FOR HASHED BOUILLI.

Shake over a slow fire a bit of butter the size of an egg, and a tablespoonful of flour; when they have simmered for a minute, stir to them a little finely-chopped onion, and a dessertspoonful of minced parsley; so soon as the whole is equally browned, add sufficient pepper, salt, and nutmeg to season the hash properly, and from half to three quarters of a pint of boiling water or of bouillon. Put in the beef cut into small but thick slices; let it stand by the fire and heat gradually; and when near the point of boiling thicken the sauce with the yolks of three eggs, mixed with a tablespoonful of lemon-juice. For change, omit the eggs, and substitute a tablespoonful of catsup, and another of pickled gherkins minced or sliced.

BAKED MINCED BEEF.

Mince tolerably fine, with a moderate proportion of its own fat, as much of the inside of a cold roast joint as will suffice for a dish: that which is least done is best for the purpose. Season it rather highly with cayenne and mace or nutmeg, and moderately with salt; add, when they are liked, one or two eschalots minced small, with a few chopped mushrooms either fresh or pickled, or two tablespoonsful of mushroom catsup. Mix the whole well with a cupful of _good_ gravy, and put it into a deep dish. Place on the top an inch-thick layer of bread-crumbs, moisten these plentifully with clarified butter passed through a small strainer over them, and send the mince to a slow oven for twenty minutes, or brown it in a Dutch oven.

SAUNDERS.

Spread on the dish in which the saunders are to be served, a layer of smoothly mashed potatoes, which have been seasoned with salt and mixed with about an ounce of butter to the pound. On these spread equally and thickly some underdressed beef or mutton minced and mixed with a little of the gravy that has run from the joint, or with a few spoonsful of any other; and season it with salt, pepper, and a small quantity of nutmeg. Place evenly over this another layer of potatoes, and send the dish to a moderate oven for half an hour. A very superior kind of saunders is made by substituting fresh meat for roasted; but this requires to be baked an hour or something more. Sausage-meat highly seasoned may be served in this way, instead of beef or mutton.

TO BOIL MARROW BONES.

Let the large ends of the bones be sawed by the butcher, so that when they are dished they may stand upright; and if it can be done conveniently, let them be placed in the same manner in the vessel in which they are boiled. Put a bit of paste, made with flour and water, over the ends where the marrow is visible, and tie a cloth tightly over them; take the paste off before the bones are sent to table, and serve them, placed upright in a napkin, with slices of dry toasted bread apart. When not wanted for immediate use, they may be partially boiled, and set into a cool place, where they will remain good for many days.

Large marrow bones, 2 hours; moderate sized, 1-1/2 hour. To keep; boil them 1-1/2 hour, and from 1/2 to 3/4 hour more when wanted for table.

BAKED MARROW BONES.

When the bones have been sawed to the length of a deep pie-dish, wash and wipe them dry, lay them into it, and cover them entirely with a good batter. Send them to a moderate oven for an hour or more, and serve them in the batter.

CLARIFIED MARROW FOR KEEPING.

Take the marrow from the bones while it is as fresh as possible; cut it small, put it into a very clean jar, and melt it with a gentle heat, either in a pan of water placed over the fire, or at the mouth of a cool oven; strain it through a muslin, let it settle for a minute or two, and pour it, clear of sediment, into small jars. Tie skins, or double folds of thick paper, over them as soon as the marrow is cold, and store it in a cool place. It will remain good for months.

OX-CHEEK STUFFED AND BAKED.

(_Good, and not expensive._)

Cleanse, with the greatest nicety, a fresh ox-cheek by washing, scraping it lightly with a knife, and soaking out the blood; then put it into plenty of warm water, and boil it gently for about an hour. Throw in a large teaspoonful of salt, and carefully remove all the scum as it rises to the surface. Let it cool after it is lifted out, and then take away the bones, remembering always to work the knife close to them, and to avoid piercing the skin. When the cheek has become cold, put into it a good roll of forcemeat, made by the receipt Nos. 1, 2, or 3, of Chapter IX., or substitute the oyster or mushroom forcemeat which follows; but in any case increase the quantity one-half at least: then skewer or bind up the cheek securely, and send it to a moderate oven for an hour or an hour and a half. It should be baked until it is exceedingly tender quite through. Drain it well from fat, dish it, withdraw the skewers, or unbind it gently, and either sauce it with a little good brown gravy, or send it to table with melted butter in a tureen, a cut lemon, and cayenne, or with any sauce of Chapter V., which may be considered more appropriate.

CHAPTER XI.

=Veal.=

[Illustration]

No. 1. Loin, Best End. 2. Loin, Chump End. 3. Fillet. 4. Hind Knuckle. 5. Fore Knuckle. 6. Neck, Best End. 7. Neck, Scrag End. 8. Blade Bone. 9. Breast, Best End. 10. Breast, Brisket End.

In season all the year, but scarce and expensive in mid-winter, and very early spring.

TO CHOOSE VEAL.

VEAL should be fat, finely grained, white, firm, and not overgrown: for when very large it is apt to be coarse and tough. It is more difficult to keep than any other meat except pork, and should never be allowed to acquire the slightest taint before it is dressed, as any approach to putridity renders it equally unwholesome and offensive to the taste. The fillet, the loin, the shoulder, and the best end of the neck, are the parts generally selected for roasting; the breast and knuckle are more usually stewed or boiled, although the former is excellent roasted. The udder or firm white fat of the fillet, is much used by French cooks instead of butter, in the composition of their forcemeats: for these, it is first well boiled, then left until quite cold, and afterwards thoroughly pounded before it is mixed with the other ingredients. The head and feet of the calf are valuable articles of food, both for the nutriment which the gelatinous parts of them afford, and for the great variety of modes in which they may be dressed. The kidneys, with the rich fat that surrounds them, and the sweetbreads, are well known delicacies; the liver and the heart also are very good eating; and no meat is so generally useful for rich soups and gravies as veal.

TO TAKE THE HAIR FROM A CALF'S HEAD WITH THE SKIN ON.

It is better to do this before the head is divided; but if only the half of one with the skin on can be procured, it must be managed in the same way. Put it into plenty of water which is on the point of simmering but which does not positively boil, and let it remain in until it does so, and for five or six minutes afterwards, but at the first full bubble draw it from the fire and let it merely scald; then lift it out, and with a knife that is _not_ sharp scrape off the hair as closely as possible. The butchers have an instrument on purpose for

the operation; but we have had the head look quite as well when done in the manner we have just described, as when it has been sent in ready prepared by them. After the hair is off, the head should be _well_ washed, and if it cannot be cooked the same day, it must be wiped extremely dry before it is hung up; and when it has not been divided, it should be left whole until the time approaches for dressing it. The brain must then be taken out, and both that and the head well soaked and washed with the greatest nicety. When the half head only is scalded, the brain should first be removed. Calves' feet are freed from the hair easily in the same manner; indeed, we find it a better mode of having it cleared from them than the one we have given in Chapter XXII., though that is practised by many good butchers.

BOILED CALF'S HEAD.

When the head is dressed with the skin on, which many persons prefer, the ear must be cut off quite close to it; it will require three quarters of an hour or upwards of additional boiling, and should be served covered with fried crumbs: the more usual mode, however, is to boil it without the skin. In either case first remove the brain, wash the head delicately clean, and soak it for a quarter of an hour; cover it plentifully with cold water, remove the scum as it rises with great care, throw in a little salt, and boil the head gently until it is perfectly tender. In the mean time, wash and soak the brains first in cold and then in warm water, remove the skin or film, boil them in a small saucepan from fourteen to sixteen minutes, according to their sage, and when they are done, chop and mix them with eight or ten size leaves boiled tender and finely minced; or, if preferred, with boiled parsley instead; warm them in a spoonful or two of melted butter, or white sauce; skin the tongue, trim off the root, and serve it in a small dish with the brains round it. Send the head to table very hot with parsley and butter poured over it, and some more in a tureen. A cheek of bacon, or very delicate pickled pork, is the usual accompaniment to boiled calf's head.

We have given here the common English mode of serving this dish, by some persons considered the best, and by others, as exceedingly insipid. On the continent, tomata sauce takes place of the parsley and butter; and rich oyster or Dutch sauce, are varieties often substituted for it in this country.

With the skin on, from 2-1/4 to 2-3/4 hours; without the skin, from 1-1/4 to 1-3/4 hour.

CALF'S HEAD, THE WARDER'S WAY.

(_An excellent Receipt._)

Boil the half-head until tolerably tender; let it cool, and bone it entirely; replace the brain, lay the head into a stewpan, and simmer it gently for an hour in rich gravy. From five-and-twenty to thirty minutes before it is dished, add half a pint of mushroom-buttons. Thicken the gravy, if needful, with rice flour or with flour and butter, and serve plenty of forcemeat-balls round the head. For dishes of this kind, a little sweet-basil wine, or a few sprigs of the herb itself, impart a very agreeable flavour. When neither these nor mushrooms are within reach, the very thin rind of a small but fresh lemon may be boiled in the gravy, and the strained juice added at the instant of serving.

Boiled from 1 to 2 hours; stewed 1 hour.

Obs.—The skin, _with the ear_, may be left on the head for this receipt, and the latter slit into narrow strips from the tip to within an inch and a half of the base; which will give it a feathery and ornamental appearance, the head may then be glazed or not at pleasure.

PREPARED CALF'S HEAD.

(_The Cook's Receipt._)

Take away the brains and tongue from the half of a calf's head, and then remove the bones, being careful in doing so to keep the knife as close to them as possible, and to avoid piercing the outer skin: in this consists the whole art of boning, in which an attentive cook may easily render herself expert. Next wash the head and dry it in a clean cloth; sprinkle over the inside a little pounded mace, and cayenne or white pepper; roll it up tightly, and bind it round with tape or twine. Lay into a small stewpot three or four pounds of neck of veal or of beef, twice or thrice divided, and place the head upon it with the bones well broken; pour in half a gallon of cold water, or as much as will suffice to keep the head covered until it is done, and simmer it very gently from an hour and a quarter to an hour and three quarters. When it is extremely tender, lift it out, and if wanted for table, remove the binding, and serve it very hot, with currie sauce, rich oyster sauce, or egg sauce and brown gravy; but should the remains, or the whole of it be required for the

following receipts, pour no gravy over it: in the latter case do not take off the tape for several hours. The tongue may be stewed with the head, but will require rather less time. We do not think it needful to repeat in every receipt our directions for adding salt to, and removing carefully the scum from, meat that is stewed or boiled, but the cook must not neglect either. When the trouble of boning is objected to, it can be dispensed with for some of the dishes which follow, but not for all. After the head is taken out, boil the gravy until it is well reduced, and rich: it should be strongly jellied when cold. A bone of ham, or a slice of hung beef will much improve its flavour; but vegetables must be avoided if it be wanted to keep: a little spice and a faggot of parsley may be added to it, and a calf's foot will be sure to give it the requisite degree of firmness. This receipt is for a head without the skin.

BURLINGTON WHIMSEY.

Set aside until quite cold half a calf's head dressed by the preceding receipt. If, on cutting it, the gelatinous part should not appear perfectly tender, pare it off closely from the head, weigh, and mince it; put it into a pint of good gravy, and stew it gently from ten to fifteen minutes. Mince as much more of the head as will make up a pound in weight after the edges are trimmed off, and part of the fat is taken away; add to this three ounces of the lean of a boiled ham finely chopped, the grated rind of a large lemon, three teaspoonsful of parsley and one of thyme shred very small, three quarters of a teaspoonful of mace, half a small nutmeg grated, a teaspoonful of salt, and a half-quarter one of cayenne; stir the whole well together, and put it, with half a pint more of gravy, to the portion which has been already simmered. When the whimsey has boiled _softly_ from four to five minutes, pour it into moulds or pans, in which slices of the tongue have been evenly arranged, and when quite cold it will turn out very firmly. It may be garnished, before it is sent to table, with branches of parsley, which should, however, be perfectly dry; and when served for supper or luncheon, it may be accompanied by a salad dressing.

Calf's head, 1 lb.; lean of ham, 3 oz.; gravy, 1-1/2 pint; rind of 1 large lemon; parsley, 3 teaspoonsful; thyme and salt, each 1 teaspoonful; mace, 3/4 teaspoonful; 1/2 nutmeg; cayenne, 1/8 part of teaspoonful: 5 minutes.

Obs.—The remains of a plain boiled head may be made to serve for this dish, provided the gravy used with it be well jellied and of high flavour. Slices from the small end of a boiled and smoked ox-tongue, from their bright colour improve greatly its appearance. It should be tasted before it is poured out, that salt or any other seasoning may be added if needful. After three or four days' keeping, should any mould appear upon the surface, take it off, re-melt the whimsey, and give it two minutes' boil. For change, the herbs may be omitted, and the quantity of ham increased, or some minced tongue substituted for it.

CUTLETS OF CALF'S HEAD.

Prepare, by the Cook's Receipt, half a calf's head with or without the skin on; only, in the latter case, allow more time for the boiling. When it is quite cold, remove the fillets of tape, and cut the head into slices of half an inch thick, brush them with yolk of egg, and dip them into fine bread-crumbs, seasoned with the grated rind of half a lemon, half a teaspoonful of minced savoury herbs, some cayenne, and a little of the lean of a boiled ham chopped very small, should this last be at hand. Fry the cutlets in butter of a fine light brown, make some gravy in the pan as for veal cutlets, and add to it the juice of half a lemon; or mix a large teaspoonful of currie-powder, and one of flour, very smoothly with the butter, shake them over the fire for four or five minutes, and let the gravy simmer as much longer, after the water is added; or serve the cutlets, covered with good mushroom sauce.

HASHED CALF'S HEAD. (REMOVE.)

When the whole of this dish has to be prepared, make for it a quart of stock, and proceed in all else as directed for mock turtle soup (page 24); but after the head has been parboiled, cut down a full pound and a half of it for the hash, and slice it small and thick, instead of dividing it into dice. Make the brains into cakes (see page 162), and garnish the dish with forcemeat-balls, rolled in egg, and in the finest bread-crumbs, then fried a delicate brown, and well drained, and dried upon a warm sieve reversed. The wine and other seasonings should be the same as for the soup. Rich gravy, 1 quart; flesh of calf's head, full 1-1/2 lb.; wine, and other seasonings, as for mock turtle soup. _Obs._—The gravy for this should be stewed with ham, eschalots, &c., exactly as for the soup.

CHEAP HASH OF CALF'S HEAD.

Take the flesh from the bone of a cold boiled head, and put it aside until wanted; take about three pints of the liquor in which it was cooked; break the bones, and stew them down with a small bunch of savoury herbs, a carrot, or two should they be small, a little carefully fried onion, four cloves, a dozen corns of pepper, and either a slice or two of lean ham or of smoked beef. When the liquid

is reduced nearly half, strain it, take off the fat, thicken it with a little well made roux, or, if more convenient, with flour and butter, stirred into it, when it boils, or with rice flour or arrow-root, mixed with a little spice, mushroom catsup, or Harvey's sauce, and a small quantity of lemon pickle or chili vinegar. Heat the meat slowly in the sauce when it is ready, but do not allow it to boil. The forcemeat, No. 1, of Chapter VIII., may be rolled into balls, fried, and served round it. The gravy should be _well_ seasoned. A little of Liebeg's extract of beef (see Chapter I.), or as much good beef broth as may be required for the hash, will convert this into a really good dish. For preparations which are of themselves insipid, the _Jewish_ beef, of which we have often already spoken, is an admirable addition.

TO DRESS COLD CALF'S HEAD OR VEAL

À LA MÂITRE D'HÔTEL. (GOOD.)

(_English Receipt._)

Cut into small delicate slices, or into scollops of equal size, sufficient cold calf's head or veal for a dish. Next knead very smoothly together with a knife two ounces of butter, and a small dessertspoonful of flour; put these into a stewpan or well tinned saucepan, and keep them stirred or shaken over a gentle fire until they have simmered for a minute or two, but do not let them take the slightest colour; then add to them in very small portions (letting the sauce boil up after each is poured in) half a pint of pale veal gravy, or of good shin-of-beef stock, and when the whole is very smoothly blended, and has boiled for a couple of minutes, mix together and stir to it a tablespoonful of common vinegar, a dessertspoonful of chili vinegar, a little cayenne, a tablespoonful of good mushroom catsup, and a _very small_ bit of sugar; and when the sauce again boils, strew a tablespoonful of minced parsley over the meat, lay it in, and let it stand by the fire until it is quite heated through, but do not allow it to boil: if kept just at the simmering point for ten or twelve minutes it may be served perfectly hot without. The addition of the mushroom catsup converts this into an English sauce, and renders it in colour, as well as in flavour, unlike the French one which bears the same name, and which is acidulated generally with lemon-juice instead of vinegar. Pickled mushrooms are sometimes added to the dish: the parsley when it is objected to may be omitted, and the yolks of two or three eggs mixed with a little cream may be stirred in, but not allowed to boil, just before the meat is served. When veal is used for this hash instead of calf's, it should be cut into slices not much larger than a shilling, and freed entirely from fat, sinew, and the brown edges. When neither broth nor gravy is at hand, a morsel or two of lean ham, and a few of the trimmings or bones of the head or joint, may be boiled down to supply its place.

Sufficient cold calf's head, or meat, for a dish; butter, 2 oz.; flour, 1 small dessertspoonful; gravy, or strong broth, 1/2 pint; vinegar, and mushroom catsup, of each 1 tablespoonful; chili vinegar, 1 dessertspoonful; _small_ bit of sugar; little cayenne, and salt if needed; parsley, 1 tablespoonful (pickled mushrooms or not at pleasure).

Obs.—Soles or cod-fish are very good, if raised neatly from the bones, or _flaked_, and heated in this _Mâitre d'Hôtel_ sauce.

CALF'S HEAD BRAWN.

(_Author's Receipt._)

The half of a fine large calf's head with the skin on, will best answer for this brawn. Take out the brains, and bone it entirely, or get the butcher do this; rub a little fine salt over, and leave it to drain for ten or twelve hours; next wipe it dry, and rub it well in every part with three quarters of an ounce of saltpetre finely powdered (or with an ounce should the head be _very_ large) and mixed with four ounces of common salt, and three of bay-salt, also beaten fine; turn the head daily in this pickle for four or five days, rubbing it a little each time; and then pour over it four ounces of treacle, and continue to turn it every day, and baste it with the brine very frequently for a month. Hang it up for a night to drain, fold it in brown paper, and send it to be smoked where wood only is burned, from three to four weeks. When wanted for table, wash and scrape it very clean, but do not soak it; lay it, with the rind downwards, into a saucepan or stewpan, which will hold it easily; cover it _well_ with cold water, as it will swell considerably in the cooking; let it heat rather slowly, skim it thoroughly when it first begins to simmer, and boil it as gently as possible from an hour and three quarters to a couple of hours or more, should it not then be _perfectly_ tender quite through; for unless sufficiently boiled, the skin, which greatly resembles brawn, will be unpleasantly tough when cold. When the fleshy side of the head is done, which will be twenty minutes or half an hour sooner than the outside, pour the water from it, leaving so much only in the stewpan as will just cover the gelatinous part, and simmer it until this is thoroughly tender. The head thus cured is very highly flavoured, and most excellent eating. The receipt for it is entirely new, having originated with ourselves. We give the reader, in addition, the result of our _first_ experiment with it, which was entirely successful:—"A half calf's head, not very large, without the skin, pickled with three ounces of

common salt, two of bay-salt, half an ounce of saltpetre, one ounce of brown sugar, and _half an ounce of pepper_, left four days; then three ounces of treacle added, and the pickling continued for a month; smoked nearly as long, and boiled between one hour and a half, and two hours." The pepper was omitted in our second trial, because it did not improve the appearance of the dish, although it was an advantage in point of flavour. Juniper-berries might, we think, be added with advantage, when they are liked; and cayenne tied in a muslin might supply the place of the pepper. It is an infinite improvement to have the skin of the head left on.

TO ROAST A FILLET OF VEAL.

Take out the bone and put a good roll of forcemeat (No. 1, Chapter VIII.) under the flap, dividing first, with a sharp knife, the skin from the meat sufficiently to admit the quantity required; secure it well, truss the veal firmly into good shape, place it at a distance from the fire at first, and baste it with butter. The outside will have a richer crust of browning if the meat be washed, wiped tolerably dry, and well floured before it is laid to the fire. It should be carefully watched, and basted often, that the fat may not burn. Pour melted butter over it after it is dished, and serve with it a boiled cheek of bacon and a lemon. Roast it from three hours and a half, to four hours and a half, according to its size.

FILLET OF VEAL, AU BÉCHAMEL, WITH OYSTERS.

Roast, in the usual way, a delicate fillet of veal, and in preparing it for the spit be careful to bind it up tightly, so that no cavity may be left where the bone has been taken out. While it is at the fire, plump gently in their own strained liquor, without allowing them to boil, half a pint of fine native oysters, and, after having freed them from the beards, set them aside; then boil the beards for fifteen or twenty minutes in nearly three quarters of a pint of good veal stock, or in strong veal broth, made for the purpose; strain them out, add the liquor of the oysters, also passed through a muslin or other fine strainer, and convert the broth into rich white sauce, of which there should be a full pint. When the veal is ready to serve, take it from the spit, dish it in a very hot dish, and cut out quickly from the centre in a cup-like form, about a pound of the meat, leaving a wide margin round the joint, to be carved in the usual way. Mince, as rapidly as possible, the white part of the veal which has been cut from the fillet, and the plumped oysters; put the whole into the white sauce, which should be ready heated, bring it to the _point_ of boiling, pour it into the fillet, and send it immediately to table. The joint should be placed under a well-heated cover, while the mince is in course of preparation, and be kept near the fire.

When the knuckle of veal has been sent in with the fillet, a few thick slices from it may be taken for the sauce; but it should be boiled down sufficiently early to allow it to cool, and to have every particle of fat removed from it before it is used. A pound of the meat ought to make, with the addition of the oyster liquor, sufficient gravy for the sauce. When expense is not a consideration, the _béchamel_ of Chapter V. may be made for it, and the fillet may be filled up entirely with whole oysters heated in it; or these may be intermixed with the veal cut into shilling-sized collops. Mushroom-buttons, stewed white in butter, can be substituted for the oysters, when their season is past; and very small forcemeat balls, delicately fried, may then be piled entirely over the open part of the fillet.

Persons who may take exception at the idea of _oysters with roast veal_, as not being in accordance with the common etiquette of the table, are recommended to give the innovation a trial before they reject its adoption.

BOILED FILLET OF VEAL.

A small and delicately white fillet should be selected for this purpose. Bind it round with tape, after having washed it thoroughly; cover it well with cold water, and bring it gently to boil; watch, and clear off carefully, the scum as it rises, and be, at the same time, very cautious not to allow the water to become smoked. Let the meat be _gently simmered_ from three hours and a half to four and a half, according to its weight. Send it to table with rich white sauce, and a boiled tongue; or make for it in the first instance the oyster forcemeat of Chapter VIII., and serve with the veal a tureen of well-made oyster sauce.

3-1/2 to 4-1/2 hours.

ROAST LOIN OF VEAL.

It is not usual to stuff a loin of veal, but we greatly recommend the practice, as an infinite improvement to the joint. Make the same forcemeat as for the fillet; and insert it between the skin and the flesh just over the ends of the bones. Skewer down the flap, place the joint at a moderate distance from a sound fire, keep it constantly basted, and be especially careful not to allow the kidney fat to burn: to prevent this, and to ensure the good appearance of the joint, a buttered paper is often fastened round the loin, and

removed about half an hour before it is taken from the fire. It is the fashion in some counties to serve _egg-sauce_ and brown gravy with roast loin, or breast of veal.

The cook will scarcely need to be told that she must separate the skin from the flank, with a sharp knife, quite from the end, to the place where the forcemeat is to be put, and then skewer the whole very securely. When the veal is not papered, dredge it well with flour soon after it is laid to the fire.

2 to 2-1/2 hours.

BOILED LOIN OF VEAL.

If dressed with care and served with good sauces, this, when the meat is small and white is an excellent dish, and often more acceptable to persons of delicate habit than roast veal. Take from eight to ten pounds of the best end of the loin, leave the kidney in with all its fat, skewer or bind down the flap, lay the meat into cold water, and boil it _as gently as possible_ from two hours and a quarter to two and a half, clearing off the scum perfectly, as in dressing the fillet. Send it to table with well-made oyster sauce, or _béchamel_, or with white sauce well flavoured with lemon-juice, and with parsley, boiled, pressed dry, and finely chopped.

2-1/4 to 2-1/2 hours.

STEWED LOIN OF VEAL.

Take part of a loin of veal, the chump end will do; put into a large, thick, well-tinned iron saucepan, or into a stewpan, about a couple of ounces of butter, and shake it over a moderate fire until it begins to brown; flour the veal well all over, lay it into the saucepan, and when it is of a fine, equal, light brown, pour gradually in veal broth, gravy, or boiling water to nearly half its depth; add a little sauce, one or two sliced carrots, a small onion, or more when the flavour is much liked, and a bunch of parsley; stew the veal very softly for an hour or rather more; then turn it, and let it stew for nearly or quite another hour, or longer should it not be perfectly tender. As none of our receipts have been tried with large, coarse veal, the cooking must be regulated by that circumstance, and longer time allowed should the meat be of more than moderate size. Dish the joint, skim all the fat from the gravy, and strain it over the meat; or keep the joint hot while it is rapidly reduced to a richer consistency. This is merely a plain family stew.

BOILED BREAST OF VEAL.

Let both the veal and the sweetbread be washed with exceeding nicety, cover them with cold water, clear off the scum as it rises, throw in a _little_ salt, add a bunch of parsley, a large blade of mace, and twenty white peppercorns; simmer the meat from an hour to an hour and a quarter, and serve it covered with rich onion sauce. Send it to table very hot. The sweetbread may be taken up when half done, and curried, or made into cutlets, or stewed in brown gravy. When onions are objected to, substitute white sauce and a cheek of bacon for them, or parsley and butter, if preferred to it.

1 to 1-1/4 hour.

TO ROAST A BREAST OF VEAL.

Let the caul remain skewered over the joint till with within half an hour of its being ready for table: place it at a moderate distance from a brisk fire, baste it constantly, and in about an hour and a half remove the caul, flour the joint, and let it brown. Dish and pour melted butter over it, and serve it with a cut lemon, and any other of the usual accompaniments to veal. It may be garnished with fried balls of the forcemeat (No. 1, Chapter VIII.) about the size of a walnut.

2 to 2-1/2 hours.

TO BONE A SHOULDER OF VEAL, MUTTON, OR LAMB.

[Illustration:

Shoulder of Veal boned.]

Spread a clean cloth upon a table or dresser, and lay the joint flat upon it, with the skin downwards; with a sharp knife cut off the flesh from the inner side nearly down to the blade bone, of which detach the edges first, then work the knife _under_ it, keeping it

always _close to the bone_, and using all possible precaution not to pierce the outer skin; when it is in every part separated from the flesh, loosen it from the socket with the point of the knife, and remove it; or, without dividing the two bones, cut round the joint until it is freed entirely from the meat, and proceed to detach the second bone. That of the knuckle is frequently left in, but for some dishes it is necessary to take it out; in doing this, be careful not to tear the skin. A most excellent grill may be made by leaving sufficient meat for it upon the bones of a shoulder of mutton, when they are removed from the joint: it will be found very superior to the broiled blade-bone of a _roast_ shoulder, which is so much liked by many people.

STEWED SHOULDER OF VEAL.

(_English Receipt._)

Bone a shoulder of veal, and strew the inside thickly with savoury herbs minced small; season it well with salt, cayenne, and pounded mace; and place on these a layer of ham cut in thin slices and freed from rind and rust. Roll up the veal, and bind it tightly with a fillet; roast it for an hour and a half, then simmer it gently in good brown gravy for five hours; add forcemeat balls before it is dished; skim the fat from the gravy, and serve it with the meat. This receipt, for which we are indebted to a correspondent on whom we can depend, and which we have not therefore considered it necessary to test ourselves, is for a joint which weighs ten pounds before it is boned.

ROAST NECK OF VEAL.

The best end of the neck will make an excellent roast. A forcemeat may be inserted between the skin and the flesh, by first separating them with a sharp knife; or the dish may be garnished with the forcemeat in balls. From an hour and a half to two hours will roast it. Pour melted butter over it when it is dished, and serve it like other joints. Let it be floured when first laid to the fire, kept constantly basted, and always at a sufficient distance to prevent its being scorched.

1-1/2 to 2 hours.

For the forcemeat, see No. 1, Chapter VIII. From 8 to 10 minutes will fry the balls.

NECK OF VEAL À LA CRÊME.

(_Or Au Béchamel._)

Take the best end of a neck of white and well-fed veal, detach the flesh from the ends of the bones, cut them sufficiently short to give the joint a good square form, fold and skewer the skin over them, wrap a buttered paper round the meat, lay it at a moderate distance from a clear fire, and keep it well basted with butter for an hour and a quarter; then remove the paper and continue the basting with a pint, or more, of _béchamel_ or of rich white sauce, until the veal is sufficiently roasted, and well encrusted with it. Serve some _béchamel_ under it in the dish, and send it very hot to table. For variety, give the _béchamel_ in making it a high flavour of mushrooms, and add some small buttons stewed very white and tender, to the portion reserved for saucing the joint.

2 to 2-1/4 hours.

VEAL GOOSE.

(_City of London receipt._)

“This is made with the upper part of the flank of a loin of veal (or sometimes that of the fillet) covered with a stuffing of sage and onions, then rolled, and roasted or broiled. It is served with brown gravy and apple sauce, is extremely savoury, and has many admirers.” We transcribe the exact receipt for this dish, which was procured for us from a house in the city, which is famed for it. We had it tested with the skin of the best end of a fine _neck_ of veal, from which it was pared with something more than an inch depth of the flesh adhering to it. It was roasted one hour, and answered extremely well. It is a convenient mode of dressing the flank of the veal for eaters who do not object to the somewhat coarse savour of the preparation. When the _tendrons_ or gristles of a breast, or part of a breast of veal, are required for a separate dish, the remaining portion of the joint may be dressed in this way after the bones have been taken out; or, without removing them, the stuffing may be inserted under the skin.

KNUCKLE OF VEAL EN RAGOUT.

Cut in small thick slices the flesh of a knuckle of veal, season it with a little fine salt and white pepper, flour it lightly, and fry it in butter to a pale brown, lay it into a very clean stewpan or saucepan, and just cover it with boiling water; skim it clean, and add to it a faggot of thyme and parsley, the white part of a head of celery, a small quantity of cayenne, and a blade or two of mace. Stew it very softly from an hour and three quarters to two hours and a half. Thicken and enrich the gravy if needful with rice-flour and mushroom catsup or Harvey's sauce, or with a large teaspoonful of flour, mixed with a slice of butter, a little good store-sauce and a glass of sherry or Madeira. Fried forcemeat balls of No. 1, Chapter VIII. may be added at pleasure. With an additional quantity of water, or of broth (made with the bones of the joint), a pint and a half of young green peas stewed with the veal for an hour will give an agreeable variety of this dish.

BOILED KNUCKLE OF VEAL.

After the joint has been trimmed and well washed, put it into a vessel well adapted to it in size, for if it be very large, so much water will be required that the veal will be deprived of its flavour; it should be well covered with it, and _very gently_ boiled until it is perfectly tender in every part, but not so much done as to separate from the bone. Clear off the scum with scrupulous care when the simmering first commences, and throw in a small portion of salt; as this, if sparingly used, will not redden the meat, and will otherwise much improve it. Parsley and butter is usually both poured over, and sent to table with a knuckle of veal, and boiled bacon also should accompany it. From the sinewy nature of this joint, it requires more than the usual time of cooking, a quarter of an hour to the pound not being sufficient for it.

Veal 6 to 7 lbs.: 2 hours or more.

KNUCKLE OF VEAL WITH RICE.

Pour over a small knuckle of veal rather more than sufficient water to cover it; bring it slowly to a boil; take off all the scum with great care, throw in a teaspoonful of salt, and when the joint has simmered for about half an hour, throw in from eight to twelve ounces of well washed rice, and stew the veal gently for an hour and a half longer, or until both the meat and rice are perfectly tender. A seasoning of cayenne and mace in fine powder with more salt, should it be required, must be added twenty or thirty minutes before they are served. For a superior stew good veal broth may be substituted for the water.

Veal, 6 lbs.; water, 3 to 4 pints; salt, 1 teaspoonful: 30 to 40 minutes. Rice, 8 to 12 oz.: 1-1/2 hour.

Obs.—A quart or even more of full grown green peas added to the veal as soon as the scum has been cleared off will make a most excellent stew. It should be well seasoned with white pepper, and the mace should be omitted. Two or three cucumbers, pared and freed from the seeds, may be sliced into it when it boils, or four or five young lettuces shred small may be added instead. Green onions also, when they are liked, may be used to give it flavour.

SMALL PAIN DE VEAU, OR, VEAL CAKE.

Chop separately and very fine, a pound and a quarter of veal quite free from fat and skin, and six ounces of beef kidney-suet; add a teaspoonful of salt, a full third as much of white pepper and of mace or nutmeg, with the grated rind of half a lemon, and turn the whole well together with the chopping-knife until it is thoroughly mixed; then press it smoothly into a small round baking dish, and send it to a _moderate_ oven for an hour and a quarter. Lift it into a clean hot dish, and serve it plain, or with a little brown gravy in a tureen. Three ounces of the lean of a boiled ham minced small, will very much improve this cake, of which the size can be increased at will, and proportionate time allowed for dressing it. If baked in a _hot_ oven, the meat will shrink to half its proper size, and be very dry. When done, it should be of a fine light brown, and like a cake in appearance.

Veal, 1-1/4 lb.; beef-suet, 6 oz.; salt, 1 teaspoonful; pepper and mace, or nutmeg, 3/4 teaspoonful each; rind of 1/2 lemon; ham (when added) 3 oz.; baked 1-1/4 hour.

BORDYKE VEAL CAKE.

(_Good._)

Take a pound and a half of veal perfectly clear of fat and skin, and eight ounces of the nicest striped bacon; chop them separately, then mix them well together with the grated rind of a small lemon, half a teaspoonful of salt, a fourth as much of cayenne, the third part of a nutmeg grated, and a half-teaspoonful of freshly pounded mace When it is pressed into the dish, let it be somewhat higher

in the centre than at the edge; and whether to be served hot or cold, lift it out as soon as it comes from the oven, and place it on a strainer that the fat may drain from it; it will keep many days if the under side be dry. The bacon should be weighed after the rind, and any rust it may exhibit, have been trimmed from it. This cake is excellent cold, better indeed than the preceding one; but slices of either, if preferred hot, may be warmed through in a Dutch oven, or on the gridiron, or in a few spoonsful of gravy. The same ingredients made into small cakes, well floured, and slowly fried from twelve to fifteen minutes, then served with gravy made in the pan as for cutlets, will be found extremely good.

Veal, 1-1/2 lb.; striped bacon, 8 oz.; salt and mace, 1 teaspoonful each; rind of lemon, 1; third of 1 nutmeg; cayenne, 4 grains; baked 1-1/4 to 1-1/2 hour.

FRICANDEAU OF VEAL. (ENTRÉE).

French cooks always prefer for this dish, which is a common one in their own country, that part of the fillet to which the fat or udder is attached;[76] but the flesh of the finer part of the neck or loin, raised clear from the bones, may be made to answer the purpose nearly or quite as well, and often much more conveniently, as the meat with us is not divided for sale as in France; and to purchase the entire fillet for the sake of the fricandeau would render it exceedingly expensive. Lay the veal flat upon a table or dresser, with the skin uppermost, and endeavour, with one stroke of an exceedingly sharp knife, to clear this off, and to leave the surface of the meat extremely smooth; next lard it thickly with small _lardoons_, as directed for a pheasant (page 181), and make one or two incisions in the underside with the point of a knife, that it may the better imbibe the flavour of the seasonings. Take a stewpan, of sufficient size to hold the fricandeau, and the proper quantity of vegetables compactly arranged, without much room being left round the meat. Put into it a couple of large carrots, cut in thick slices, two onions of moderate size, two or three roots of parsley, three bay leaves, two small blades of mace, a branch or two of lemon thyme, and a little cayenne, or a saltspoonful of white peppercorns. Raise these high in the centre of the stewpan, so as to support the meat, and prevent its touching the gravy. Cover them with slices of very fat bacon, and place the fricandeau gently on them; then pour in as much good veal broth, or stock, as will nearly cover the vegetables without reaching to the veal. A calf's foot, split in two, may with advantage be laid under them in the first instance. Stew the fricandeau _very_ gently for upwards of three hours, or until it is found to be extremely tender when probed with a fine skewer or a larding-pin. Plenty of live embers must then be put on the lid of the stewpan for ten minutes or a quarter of an hour, to render the lardoons firm. Lift out the fricandeau and keep it hot; strain and reduce the gravy very quickly, after having skimmed off every particle of fat; glaze the veal, and serve it on a ragout of sorrel, cucumbers, or spinach. This, though rather an elaborate receipt, is the best we can offer to the reader for a dish, which is now almost as fashionable with us as it is common on the Continent. Some English cooks have a very summary method of preparing it; they merely lard and boil the veal until they can "cut it with a spoon." then glaze and serve it with "brown gravy in the dish." This may be very tolerable eating, but it will bear small resemblance to the French fricandeau.

Footnote 76:

Called by them the _noix_.

3-1/2 to 4 hours.

SPRING-STEW OF VEAL.

Cut two pound of veal, free from fat, into small half-inch thick cutlets; flour them well, and fry them in butter with two small cucumbers sliced, sprinkled with pepper, and floured, one moderate sized lettuce, and twenty-four green gooseberries cut open lengthwise and seeded. When the whole is nicely browned, lift it into a thick saucepan, and pour gradually into the pan half a pint, or rather more, of boiling water, broth, or gravy. Add as much salt and pepper as it requires. Give it a minute's simmer, and pour it over the meat, shaking it well round the pan as this is done. Let the veal stew gently from three quarters of an hour to an hour. A bunch of green onions cut small may be added to the other vegetables if liked; and the veal will eat better, if slightly seasoned with salt and pepper before it is floured; a portion of fat can be left on it if preferred.

Veal 2 lbs.; cucumbers, 2; lettuce, 1; green gooseberries, 24; water or broth, 1/2 pint or more: 3/4 to 1 hour.

NORMAN HARRICO.

Brown in a stewpan or fry lightly, after having sprinkled them with pepper, salt, and flour, from two to three pounds of veal cutlets. If taken from the neck or loin, chop the bones very short, and trim away the greater portion of the fat. Arrange them as flat as they can

be in a saucepan; give a pint of water a boil in the pan in which they have been browned, and pour it on them; add a small faggot of parsley, and, should the flavour be liked, one of green onions also. Let the meat simmer softly for half an hour; then cover it with small new potatoes which have had a single boil in water, give the saucepan a shake, and let the harrico stew very gently for another half hour, or until the potatoes are quite done, and the veal is tender. When the cutlets are thick and the potatoes approaching their full size, more time will be required for the meat, and the vegetables may be at once divided: if extremely young they will need the previous boil. Before the harrico is served, skim the fat from it, and add salt and pepper should it not be sufficiently seasoned. A few bits of lean ham, or shoulder of bacon browned with the veal, will much improve this dish, and for some tastes, a little acid will render it more agreeable. Very delicate pork chops may be dressed in the same way. A cutlet taken from the fillet and freed from fat and skin, answers best for this dish. Additional vegetables, cooked apart, can be added to it after it is dished. Peas boiled very green and well drained, or young carrots sliced and stewed tender in butter, are both well suited to it.

Veal, 2 to 3 lbs.; water (or gravy), 1 pint; new potatoes 1-1/2 to 2 lbs.; faggot, parsley, and green onions: 1 hour or more.

PLAIN VEAL CUTLETS.

Take them if possible free from bone, and after having trimmed them into proper shape, beat them with a cutlet-bat or paste-roller until the fibre of the meat is thoroughly broken; flour them well to prevent the escape of the gravy, and fry them from twelve to fifteen minutes over a fire which is not sufficiently fierce to burn them before they are quite cooked through: they should be of a fine amber brown, and _perfectly done_. Lift them into a hot dish, pour the fat from the pan, throw in a slice of fresh butter, and when it is melted, stir or dredge in a dessertspoonful of flour; keep these shaken until they are well-coloured, then pour gradually to them a cup of gravy or of boiling water; add pepper, salt, a little lemon-pickle or juice, give the whole a boil, and pour it over the cutlets: a few forcemeat balls fried and served with them, is usually a very acceptable addition to this dish, even when it is garnished or accompanied with rashers of ham or bacon. A morsel of _glaze_, or of the jelly of roast meat, should when at hand be added to the sauce, which a little mushroom powder would further improve: mushroom sauce, indeed, is considered by many epicures, as indispensable with veal cutlets. We have recommended in this one instance that the meat should be thoroughly _beaten_, because we find that the veal is wonderfully improved by the process, which, however, we still deprecate for other meat.

12 to 15 minutes.

VEAL CUTLETS A L'INDIENNE, OR INDIAN FASHION. (ENTRÉE.)

Mix well together four ounces of very fine stale bread-crumbs, a teaspoonful of salt, and a tablespoonful of the best currie powder. Cut down into small well-shaped cutlets or collops, two pounds of veal free from fat, skin, or bone; beat the slices flat, and dip them first into some beaten egg-yolks, and then into the seasoned crumbs; moisten them again with egg, and pass them a second time through bread-crumbs. When all are ready, fry them in three or four ounces of butter over a moderate fire, from twelve to fourteen minutes. For sauce, mix smoothly with a knife, a teaspoonful of flour and an equal quantity of currie-powder, with a small slice of butter; shake these in the pan for about five minutes, pour to them a cup of gravy or boiling water, add salt and cayenne if required and the strained juice of half a lemon; simmer the whole till well flavoured, and pour it round the cutlets. A better plan is, to have some good currie sauce ready prepared to send to table with this dish; which may likewise be served with only well-made common cutlet gravy, from the pan, when much of the pungent flavour of the currie-powder is not desired.

Bread-crumbs, 4 oz.; salt, 1 teaspoonful; currie powder, 1 tablespoonful; veal, 2 lbs.: 12 to 14 minutes.

Obs.—These cutlets may be broiled; they should then be well beaten first, and dipped into clarified butter instead of egg before they are passed through the curried seasoning.

VEAL CUTLETS, OR COLLOPS, À LA FRANÇAISE. (ENTRÉE.)

Cut the veal into small, thin, round collops of equal size, arrange them evenly in a sauté-pan, or in a small frying-pan, and sprinkle a little fine salt, white pepper, and grated nutmeg on them. Clarify, or merely dissolve in a clean saucepan with a gentle degree of heat, an ounce or two of good butter, and pour it equally over the meat. Set the pan aside until the dinner-hour, then fry the collops over a clear fire, and when they are lightly browned, which will be in from four to five minutes, lift them into a hot dish, and sauce them with a little _Espagnole_, or with a gravy made quickly in the pan, and flavoured with lemon-juice and cayenne. They are excellent even without any sauce.

3 to 4 minutes.

SCOTCH COLLOPS. (ENTRÉE.)

Prepare the veal as for the preceding receipt, but dip the collops into beaten egg and seasoned bread-crumbs, and fry them directly in good butter, over a moderate fire, of a light golden brown; drain them well in lifting them from the pan, and sauce them like the collops _à la Française_.

VEAL CUTLETS À LA MODE DE LONDRES, OR, LONDON FASHION. (ENTRÉE.)

Raise the flesh entire from the upper side of the best end of a neck of veal, free it from the skin, and from the greater portion of the fat, slice it equally into cutlets little more than a quarter of an inch thick, brush them with egg, strew them with fine bread-crumbs, and fry them of a light brown. Toast, or fry apart as many small slices of bacon as there are cutlets, and let them be trimmed nearly to the same shape; place them alternately on their edges round the inside of a hot dish (so as to form a sort of chain), and pour into the middle some rich gravy made in the pan, and very slightly flavoured with eschalot; or substitute for this some good brown mushroom sauce. Savoury herbs, grated lemon-rind, nutmeg or mace, salt, and white pepper or cayenne, should be mixed with the bread-crumbs, in the proportions directed at page 213, for cutlets of calf's head; or they may be varied at pleasure. A cheek of bacon is best adapted to this dish.

SWEETBREADS SIMPLY DRESSED. (ENTRÉE.)

In whatever way sweetbreads are dressed, they should first be well soaked in lukewarm water, then thrown into boiling water to _blanch_ them, as it is called, and to render them firm. If lifted out after they have boiled from five to ten minutes according to their size, and laid immediately into fresh spring water to cool, their colour will be the better preserved. They may then be gently stewed for three quarters of an hour in veal gravy, which with the usual additions of cream, lemon, and egg-yolks, may be converted into a fricassee sauce for them when they are done; or they may be lifted from it, _glazed_, and served with good Spanish gravy; or, the glazing being omitted, they may be sauced with the sharp _Maître d'Hôtel_ sauce of page 117. They may also be simply floured, and roasted in a Dutch oven, being often basted with butter, and frequently turned. A full sized sweetbread, after having been blanched, will require quite three quarters of an hour to dress it.

Blanched 5 to 10 minutes. Stewed 3/4 hour or more.

SWEETBREAD CUTLETS. (ENTRÉE.)

Boil the sweetbreads for half an hour in water or veal broth, and when they are perfectly cold, cut them into slices of equal thickness, brush them with yolk of egg, and dip them into very fine bread-crumbs seasoned with salt, cayenne, grated lemon-rind, and mace; fry them in butter of a fine light brown, arrange them in a dish placing them high in the centre, and pour _under_ them a gravy made in the pan, thickened with mushroom powder and flavoured with lemon-juice; or, in lieu of this, sauce them with some rich brown gravy, to which a glass of sherry or Madeira has been added. When it can be done conveniently, take as many slices of a cold boiled tongue as there are sweetbread cutlets; pare the rind from them, trim them into good shape, and dress them with the sweetbreads, after they have been egged and seasoned in the same way; and place each cutlet upon a slice of tongue when they are dished. For variety, substitute _croutons_ of fried bread stamped out to the size of the cutlets with a round or fluted paste or cake cutter. The crumb of a stale loaf, very evenly sliced, is best for the purpose.

STEWED CALF'S FEET.

(_Cheap and Good._)

This is an excellent family dish, highly nutritious, and often very inexpensive, as the feet during the summer are usually sold at a low rate. Wash them with nicety, divide them at the joint, and split the claws; arrange them closely in a thick stewpan or saucepan, and pour in as much cold water as will cover them about half an inch: three pints will be sufficient for a couple of large feet. When broth or stock is at hand, it is good economy to substitute it for the water, as by this means a portion of strong and well-flavoured jellied gravy will be obtained for general use, the full quantity not being needed as sauce for the feet. The whole preparation will be much improved by laying a thick slice of the lean of an unboiled ham, knuckle of bacon, hung beef, or the end of a dried tongue, at the bottom of the pan, before the other ingredients are added; or, when none of these are at hand, by supplying the deficiency with a few bits of lean beef or veal: the feet being of themselves insipid, will be much more palatable with one or the other of these additions. Throw in from half to three quarters of a teaspoonful of salt when they begin to boil, and after the scum has been all

cleared off, add a few branches of parsley, a little celery, one small onion or more, stuck with half a dozen cloves, a carrot or two, a large blade of mace, and twenty corns of whole pepper; stew them softly until the flesh will part entirely from the bones; take it from them, strain part of the gravy, and skim off all the fat, flavour it with catsup or any other store sauce, and thicken it, when it boils, with arrow-root or flour and butter; put in the flesh of the feet, and serve the dish as soon as the whole is very hot. A glass of wine, a little lemon juice, and a few forcemeat balls, will convert this into a very superior stew; a handful of mushroom-buttons also simmered in it for half an hour before it is dished, will vary it agreeably.

Calf's feet (large), 2; water, 3 pints; salt, 1/2 to 1/3 teaspoonful; onions, 1 to 3; cloves, 6; peppercorns, 20; mace, large blade; little celery and parsley; carrots, 1 or 2: stewed softly, 2-1/2 to 3-1/4 hours. Mushroom catsup, 1 tablespoonful; flour, or arrow-root, 1 large teaspoonful; butter, 1 to 2 oz. Cayenne, to taste.

CALF'S LIVER STOVED, OR STEWED.

From three to four pounds of the best part of the liver will be sufficient for a dish of moderate size. First lard it quite through by the directions of page 181, with large lardoons, rolled in a seasoning of spice, and of savoury herbs very finely minced; then lay it into a stewpan or saucepan just fitted to its size, and pour in about half a pint of broth or gravy; heat it very gently, and throw in, when it begins to simmer, a sliced carrot, a small onion cut in two, a small bunch of parsley, and a blade of mace; stew the liver as softly as possible over a very slow fire from two hours and a half to three hours; thicken the gravy with a little brown roux (see page 107), or with a dessertspoonful of browned flour; add a couple of glasses of white wine, and a little spice if needed, and serve it very hot, after having taken out the herbs and vegetable.

The liver may be stewed without being larded; it may likewise be browned all over in a carefully made _roux_, before the gravy is poured to it: this must then be made to boil, and be added in small portions, the stewpan being well shaken round as each is thrown in. The wine can be altogether omitted; or a wineglassful of port mixed with a little lemon-juice, may take the place of sherry. After the liver has been wiped very dry, minced herbs may be strewed thickly over it before it is laid into the stewpan; and it may be served in its own gravy, or with a _sauce piquante_.

Liver, 3 to 4 lbs: 2 to 3 hours.

TO ROAST CALF'S LIVER.

Take the whole or part of a fine white sound liver, and either lard it as a fricandeau upon the surface, or with large strips of highly-seasoned bacon in the inside (see Larding, page 181); or should either of these modes be objected to, merely wrap it in a well buttered paper, and roast it from an hour to an hour and a quarter at a moderate distance from a clear fire, keeping it constantly basted. Remove the paper, and froth the liver well from ten to fifteen minutes before it is done. It should be served with a sauce of some piquancy, such as a _poivrade_, or brown eschalot, in addition to some good gravy. French cooks steep the liver over-night in vinegar, with a sliced onion and branches of savoury herbs laid over it: this whitens and renders it firm. As an economical mode, some small bits of the liver may be trimmed off, floured, and lightly fried with a sliced onion, and stewed down for gravy in three quarters of a pint of water which has been poured into the pan, with the addition of a few peppercorns, and a small bunch of herbs. A seasoning of salt must not be forgotten, and a little lemon pickle, or juice, would generally be considered an improvement.

1 to 1-1/4 hour.

BLANQUETTE OF VEAL OR LAMB, WITH MUSHROOMS.

(ENTRÉE.)

Slice very thin the white part of some cold veal, divide and trim it into scallops not larger than a shilling, and lay it into a clean saucepan or stewpan. Wipe with a bit of new flannel and a few grains of salt, from a quarter to half a pint of mushroom-buttons, and slice them into a little butter which just begins to simmer; stew them in it from twelve to fifteen minutes, without allowing them to take the slightest colour; then lift them out and lay them on the veal. Pour boiling to them a pint of _sauce tournée_ (see page 108); let the _blanquette_ remain near, but not close to the fire for awhile: bring it nearer, heat it slowly, and when it is on the point of boiling mix a spoonful or two of the sauce from it with the well beaten yolks of four fresh eggs; stir them to the remainder; add the strained juice of half a small lemon; shake the saucepan above the fire until the sauce is just set, and serve the _blanquette_ instantly.

Cold veal, 3/4 lb.; mushrooms, 1/4 to 1/2 pint: stewed in 1-1/2 oz. butter, 12 to 15 minutes. Sauce _tournée_, or thickened veal gravy, 1 pint; yolks of eggs, 4; lemon-juice, 1 tablespoonful.

Obs.—Any white meat may be served _en blanquette_. The mushrooms are not indispensable for it, but they are always a great improvement. White sauce substituted for the thickened veal gravy will at once convert this dish into an inexpensive English fricassee. Mace, salt, and cayenne, must be added to either preparation, should it require seasoning.

MINCED VEAL.

When there is neither gravy nor broth at hand, the bones and trimmings of the meat must be boiled down to furnish what is required for the mince. As cold meat is very light in weight, a pound of the white part of the veal will be sufficient for a dish, and for this quantity a pint of gravy will be needed. Break down the bones of the joint well, add the trimmings of the meat, a small bunch of savoury herbs, a slice or two of carrot or of celery, a blade of mace, a few white peppercorns, and a bit or two of lean ham, boiled, or unboiled if it can be had, as either will improve the flavour of the mince. Pour to these a pint and a half of water, and stew them gently for a couple of hours; then strain off the gravy, let it cool, and clear it entirely from the fat. Cut the white part of the veal small with a very sharp knife, after all the gristle and brown edges have been trimmed away. Some persons like a portion of fat minced with it, others object to the addition altogether. Thicken the gravy with a teaspoonful and a half of flour smoothly mixed with a small slice of butter, season the veal with a saltspoonful or more of salt, and half as much white pepper and grated nutmeg, or pounded mace; add the lightly-grated rind of half a small lemon; mix the whole well, put it into the gravy, and heat it thoroughly by the side of the fire without allowing it to boil; serve it with pale toasted sippets in and round the dish. A spoonful or two of cream is always an improvement to this mince.

MINCED VEAL AND OYSTERS.

The most elegant mode of preparing this dish is to mince about a pound of the whitest part of the inside of a cold roast fillet or loin of veal, to heat it without allowing it to boil, in a pint of rich white sauce, or _béchamel_, and to mix with it at the moment of serving, three dozens of small oysters ready bearded, and plumped in their own strained liquor, which is also to be added to the mince; the requisite quantity of salt, cayenne, and mace should be sprinkled over the veal before it is put into the sauce. Garnish the dash with pale fried sippets of bread, or with _fleurons_[77] of brioche, or of puff-paste. Nearly half a pint of mushrooms minced, and stewed white in a little butter, may be mixed with the veal instead of the oysters; or should they be very small they may be added to it whole: from ten to twelve minutes will be sufficient to make them tender. Balls of delicately fried oyster-forcemeat laid round the dish will give another good variety of it.

Footnote 77:

Fleurons, flowers, or flower-like figures, cut out with tin shapes.

Veal minced, 1 lb.; white sauce, 1 pint; oysters, 3 dozen, with their liquor; or mushrooms, 1/2 pint, stewed in butter 10 to 12 minutes.

VEAL-SYDNEY. (GOOD.)

Pour boiling on an ounce and a half of fine bread-crumbs nearly half a pint of good veal stock or gravy, and let them stand till cool; mix with them then, two ounces of beef-suet shred very small, half a pound of cold roast veal carefully trimmed from the brown edges, skin, and fat, and finely minced; the grated rind of half a lemon, nearly a teaspoonful of salt, a little cayenne, the third of a teaspoonful of mace or nutmeg, and four well-beaten eggs. Whisk up the whole well together, put it into a buttered dish, and bake it from three quarters of an hour to an hour. Cream may be used instead of gravy when more convenient, but this last will give the better flavour. A little clarified butter put into the dish before the other ingredients are poured in will be an improvement.

Bread-crumbs, 1-1/2 oz.; gravy or cream, nearly 1/2 pint; beef-suet, 2 oz.; cold veal, 1/2 lb.; rind of 1/2 lemon; salt, small teaspoonful; third as much mace and nutmeg; little cayenne; eggs, 4 large or 5 small: 3/4 to 1 hour.

FRICASSEED VEAL.

Divide into small, thick, handsome slices of equal size, about a couple of pounds of veal, quite free from fat, bone, and skin; dissolve a couple of ounces of butter in a wide stewpan, and just as it begins to boil lay in the veal, and shake it over the fire until it

is quite firm on both sides, but do not allow it to take the slightest colour. Stir in a tablespoonful of flour, and when it is well mixed with the cutlets, pour gradually to them, shaking the pan often, sufficient boiling veal gravy to almost cover them. Stew them gently from fifteen to sixteen minutes, or longer should they not be perfectly tender. Add a flavouring of mace, some salt, a quarter-pint of rich cream, a couple of egg-yolks, and a little lemon-juice, observing, when the last are added, the directions given for a _blanquette_ of veal, page 229. Strips of lemon-rind can be stewed in the gravy at pleasure. Two or three dozens of mushroom-buttons, added twenty minutes before it is served, will much improve this fricassée.

SMALL ENTRÉES OF SWEETBREADS, CALF'S BRAINS AND EARS, &c. &c.

For tables of which the service consists rather of a great variety of light dishes (_entrées_) than of substantial English fare, the ears, brains, sweetbreads, gristles or _tendrons_, and the tail of a calf, may be dressed in many different ways to supply them; but they require a really good style of cookery, and many adjuncts to render them available for the purpose, as they do not possess much decided natural flavour, and their insipidity would be apt to tire if it were not relieved by the mode of preparing them. We shall give some few especial receipts for them in the chapter on Foreign Cookery, should sufficient space remain open for us to admit them; and insert here only such slight general directions as may suffice for preparing some of them in a simple form; as they are not in reality of first-rate importance. All of them may be served with good curried, or highly-flavoured tomato-sauce, after having been stewed in strong broth or gravy. The brains and sweetbreads cut into small dice or scallops, and mixed with _béchamel_, or with common white sauce, may be used to fill small _vol-au-vents_, or patty cases. The ears are usually filled in part with forcemeat, or a preparation of the brains, and placed upright when dished; and the upper part is cut into narrow fringe-like strips. For "_Tendrons de Veau_," and "Breast of veal rolled and stewed," the reader is referred to Chapter XXXIV.

CHAPTER XII.

=Mutton.=

[Illustration]

No. 1. Leg. 2. Best End of Loin. 3. Chump End of Loin. 4. Neck, Best End. 5. Neck, Scrag End. 6. Shoulder. 7. Breast. A Saddle is the Two Loins. A Chine, the Two Necks.

Mutton is best suited for table in autumn, winter, and early spring. It is not considered quite so good when grass-lamb is in full season, nor during the sultry months of summer.

TO CHOOSE MUTTON.

THE best mutton is small-boned, plump, finely-grained, and short-legged; the lean of a dark, rather than of a bright hue, and the fat white and clear: when this is yellow, the meat is rank, and of bad quality. Mutton is not considered by experienced judges to be in perfection until it is nearly or quite five years old; but to avoid the additional expense of feeding the animal so long, it is commonly brought into the market at three years old. The leg and the loin are the superior joints; and the preference would probably be given more frequently to the latter, but for the superabundance of its fat, which renders it a not very economical dish. The haunch consists of the leg and the part of the loin adjoining it; the saddle, of the two loins together, or of the undivided _back_ of the sheep: these last are always roasted, and are served usually at good tables, or for company-dinners, instead of the smaller joints. The shoulder, dressed in the ordinary way, is not very highly esteemed, but when boned, rolled, and filled with forcemeat, it is of more presentable appearance, and to many tastes, far better eating; though some persons prefer it in its natural form, accompanied by stewed onions. It is occasionally boiled or stewed, and covered with rich onion sauce. The flesh of that part of the neck which is commonly called the "best end," or the _back ribs_, and which adjoins the loin, is the most succulent and tender portion of the sheep, and makes an excellent small roast, and is extremely good served as cutlets, after being divested of the superabundant fat. It is likewise very frequently boiled; but so cooked it makes but an unsightly and insipid dish, though an idea prevails in this country that it is a very wholesome one. Cutlets (or _chops_, as the butchers term them) are commonly taken from the loin, and are generally charged at a higher rate than _joints_ of mutton, in consequence, probably, of the constant demand for them. They may likewise be cut from the saddle, but will then be very large, and of no better quality than when the two loins which form the saddle are divided in the usual way, though a certain degree of fashion has of late been accorded to them.[78] The scrag, or that part of it

which joins the head, is seldom used for any other purpose than making broth, and should be taken off before the joint is dressed. Cutlets from the thick end of the loin are commonly preferred to any others, but they are frequently taken likewise from the best end of the neck (sometimes called the _back-ribs_) and from the middle of the leg. Mutton kidneys are dressed in various ways, and are excellent in many. The trotters and the head of a sheep may be converted into very good dishes, but they are scarcely worth the trouble which is required to render them palatable. The loin and the leg are occasionally cured and smoked like hams or bacon.

Footnote 78:

Many years since, these "_saddle-back_" cutlets were supplied to us by a country butcher, and though of very fine South Down mutton, had no particular importance attached to them, nor were they considered as remarkably new.

TO ROAST A HAUNCH OF MUTTON.[79]

Footnote 79:

We recommend Liebig's directions for roasting (page 171), to be applied here, and for the joints which follow.

This joint should be well kept, and when the larder-accommodations of a house not are good, the butcher should be requested to hang it the proper time. Roast it carefully at a large sound fire, and let it remain at a considerable distance for at least a couple of hours; then draw it nearer, but never sufficiently so to burn or injure the fat. Keep it constantly basted; flour it soon after it is laid to the fire, instead of frothing it, as this latter mode is not generally relished, though fashion is in its favour. In from three and a half to four hours, the haunch will be done, and it will require something less of time when not kept back at first, as we have advised. Serve it with a good _Espagnole_, or with plain mutton-gravy and currant-jelly. This joint, when the meat is of very fine quality, may be dressed and served exactly like venison.

3-1/2 to 4 hours. 5 hours or more by the _slow_ method.

ROAST SADDLE OF MUTTON.

This is an excellent joint, though not considered a very economical one. It is usual for the butcher to raise the skin from it before it is sent in, and to skewer it on again, that in the roasting the juices of the meat may be better preserved, and the fat prevented from taking too much colour, as this should be but delicately browned. In less than half an hour before the mutton is done, remove the skin, and flour the joint lightly after having basted it well. Our own great objection to frothed meat would lead us to recommend that the skin should be taken off half an hour earlier, and that the joint should be kept at sufficient distance from the fire to prevent the possibility of the fat being burned; and that something more of time should be allowed for the roasting. With constant basting, great care, and good management, the cook may always ensure the proper appearance of this, or of any other joint (except, perhaps, of a haunch of venison) without having recourse to papering or pasting, or even to replacing the skin; but when unremitted attention cannot be given to this one part of the dinner, it is advisable to take all precautions that can secure it from being spoiled.

2-1/2 to 2-3/4 hours. More if _very_ large.

TO ROAST A LEG OF MUTTON.

In a cool and airy larder a leg of mutton will hang many days with advantage, if the kernel be taken out, and the flap wiped very dry when it is first brought in; and it is never tender when freshly killed: in warm weather it should be well dredged with pepper to preserve it from the flies. If washed before it is put upon the spit, it should be wiped as dry as possible afterwards, and well floured soon after it is laid to the fire. When the excellence of the joint is more regarded than the expense of fuel, it should be roasted by what we have denominated the _slow method_; that is to say, it should be kept at a considerable distance from the fire, and remain at it four hours instead of two: it may be drawn nearer for the last twenty or thirty minutes to give it colour. The gravy will flow from it in great abundance when it is cut, and the meat will be very superior to that roasted in the usual way. When this plan is not pursued, the mutton should still be kept quite a foot from the fire until it is heated through, and never brought sufficiently near to scorch or to harden any part. It should be _constantly basted_ with its own fat, for if this be neglected, all other precautions will fail to ensure a good roast; and after it is dished a little fine salt should be sprinkled lightly on it, and a spoonful or two of boiling water ladled over. This is the most palatable mode of serving it, but it may be frothed when it is preferred so, though we would rather recommend that the flour should be dredged on in the first instance, as it then prevents the juices of the meat from escaping, and forms a savoury coating to it; while the raw taste which it so often retains with mere frothing is to many eaters especially

objectionable.

Leg of mutton, 7 to 8 lbs.: slow method 4 hours, common method 1-3/4 to 2 hours.

Obs.—Many common cooks injure their roasts exceedingly by pouring abundance of hot water over them, "_to make gravy_" as they call it. This should never be done. The use of any portion may, perhaps, be rationally objected to; but when the joint is not carefully cooked it is sometimes very dry without it. A few spoonsful of Liebeg's extract of meat will supply excellent gravy for this, or for any other dish of roasted meat.

BRAISED LEG OF MUTTON.

Take out the bone as far as the first joint by the directions of the following receipt; roll some large strips of bacon in a seasoning of mixed spice, and of savoury herbs minced extremely fine or dried and reduced to powder, and with these lard the inside of the boned portion of the joint; or fill the cavity with forcemeat highly seasoned with eschalot or garlic. Sew up the meat, and place it in a braising-pan or ham-kettle nearly of its size, with slices of bacon under and over it, two or three onions, four or five carrots, two bay leaves, a large bunch of savoury herbs, a few bones, or bits of undressed mutton or veal, and about three quarters of a pint of gravy. Stew the meat as softly as possible from four to five hours, and keep live embers on the pan (or, as this mode of cooking is not general in England, set the mutton, if it can be done conveniently, into a moderately-heated oven, after having luted the edges of the vessel in which it is arranged with a bit of coarse paste); lift it out, strain the gravy, reduce it quickly to glaze, and brush the meat with it; or merely strain, free it from fat, and pour it over the mutton. White beans (_haricots blancs_), boiled tender and well drained, or a mild ragout of garlic or eschalots, may be laid in the dish under it. The joint can be braised equally well without any part of it being boned.

3 to 5 hours.

LEG OF MUTTON BONED AND FORCED.

Select for this dish a joint of South Down or of any other delicate-sized mutton, which has been kept sufficiently long to render it very tender. Lay it on a clean cloth spread upon a table, and turn the underside upwards. With a sharp-edged boning-knife cut through the middle of the skin, from the knuckle to the first joint, and raise it from the flesh on the side along which the bone runs, until the knife is just above it, then cut through the flesh down to the bone; work the knife round it in every part till you reach the socket; next remove the flat bone from the large end of the joint, and pass the knife freely round the remaining one, as it is not needful to take it out clear of the meat; when you again reach the middle joint, loosen the skin round it with great care, and the two bones can then be drawn out without being divided. This being done, fill the cavities with the forcemeat, No. 1. (Chapter VIII.), adding to it a somewhat high seasoning of eschalot, garlic, or onion; or cut out with the bone, nearly a pound of the inside of the mutton, chop it fine with six ounces of delicate striped bacon, and mix with it thoroughly three quarters of an ounce of parsley, and half as much of thyme and winter savoury, all minced extremely small; a half teaspoonful of pepper (or a third as much of cayenne); the same of mace, salt, and nutmeg, and either the grated rind of a small lemon, or four eschalots finely shred. When the lower part of the leg is filled, sew the skin neatly together where it has been cut open, and tie the knuckle round tightly, to prevent the escape of the gravy. Replace the flat bone at the large end, and with a long needle and twine, draw the edges of the meat together over it. If it can be done conveniently, it is better to roast the mutton thus prepared in a cradle spit or upon a bottle-jack, with the knuckle downwards. Place it at first far from the fire, and keep it constantly basted. It will require nearly or quite three hours' roasting. Remove the twine before it is served, and send it very hot to table with some rich brown gravy.

A BOILED LEG OF MUTTON WITH TONGUE AND TURNIPS.

(_An excellent Receipt._)

Trim into handsome form a well-kept, but perfectly sweet leg of mutton, of middling weight; wash, but do not soak it; lay it into a vessel as nearly of its size as convenient, and pour in rather more than sufficient cold water[80] to cover it; set it over a good fire, and when it begins to boil take off the scum, and continue to do so until no more appears; throw in a tablespoonful of salt (after the first skimming), which will assist to bring it to the surface, and as soon as the liquor is clear, add two moderate-sized onions stuck with a dozen cloves, a large faggot of parsley, thyme, and winter savoury, and four or five large carrots, and half an hour afterwards as many turnips. Draw the pan to the side of the fire, and let the mutton be simmered _gently_ from two hours to two and a half, from the time of its first beginning to boil. Serve it with caper, brown cucumber, or oyster sauce. If stewed _softly_, as we have

directed, the mutton will be found excellent dressed thus; otherwise, it will but resemble the unpalatable and ragged-looking joints of fast-boiled meat, so constantly sent to table by common English cooks. Any undressed bones of veal, mutton, or beef, boiled with the joint will improve it much, and the liquor will then make excellent soup or _bouillon_. A small smoked ox-tongue boiled very tender will generally be much approved as an accompaniment to the mutton, though it is out of the usual course to serve them together: innovation on established usages is, however, sometimes to be recommended. The tongue should be garnished with well-prepared mashed turnips, moulded with a tablespoon into the form of a half-egg, and sent to table as hot as possible; or the turnips may be dished apart.

Footnote 80:

We have left this receipt unaltered, instead of applying to it Baron Liebeg's directions for his improved method of boiling meat, because his objections to the immersion of the joint in _cold_ water are partially obviated, by its being placed immediately over a sound fire, and heated quickly; and the mutton is very good thus dressed.

2 to 2-1/2 hours.

ROAST OR STEWED FILLET OF MUTTON.

Cut some inches from either end of a large and well-kept leg of mutton, and leave the fillet shaped like one of veal. Remove the bone, and fill the cavity with forcemeat (No. 1, Chapter VIII.), which may be flavoured with a little minced eschalot, when its flavour is liked: more forcemeat may be added by detaching the skin sufficiently on the flap side to admit it. When thus prepared, the fillet may be roasted, and served with currant-jelly and brown gravy, or with only melted butter poured over it; or it may be stewed gently for nearly or quite four hours, in a pint of gravy or broth, after having been floured and browned all over in a couple of ounces of butter: it must then be turned every hour that it may be equally done. Two or three small onions, a faggot of herbs, a couple of carrots sliced, four or five cloves, and twenty whole peppercorns can be added to it at will.

Roasted 2 hours, or stewed 4 hours.

Obs.—At a large fire, half an hour less of time will roast the mutton sufficiently for English taste in general.

TO ROAST A LOIN OF MUTTON.

The flesh of the loin of mutton is superior to that of the leg, when roasted; but to the frugal housekeeper this consideration is usually overbalanced by the great weight of fat attached to it; this, however, when economy is more considered than appearance, may be pared off and melted down for various kitchen uses. When thus reduced in size, the mutton will be soon roasted. If it is to be dressed in the usual way, the butcher should be desired to take off the skin; and care should be taken to preserve the fat from being ever so lightly burned: it should be managed, indeed, in the same manner as the saddle, in every respect, and carved also in the same way, either in its entire length or in oblique slices.

Without the fat, 1 to 1-1/2 hour; with 1-1/4 to 1-3/4 hour.

TO DRESS A LOIN OF MUTTON LIKE VENISON.

Skin and bone a loin of mutton, and lay it into a stewpan, or braising-pan, with a pint of water, a large onion stuck with a dozen cloves, half a pint of port wine and a spoonful of vinegar; add, when it boils, a small faggot of thyme and parsley, and some pepper and salt: let it stew three hours, and turn it often. Make some gravy of the bones, and add it at intervals to the mutton when required. This receipt comes to us so strongly recommended by persons who have partaken frequently of the dish, that we have not thought it needful to prove it ourselves.

3 hours.

ROAST NECK OF MUTTON.

This is a very favourite joint in many families, the flesh being more tender and succulent than that even of the loin; and when only a small roast is required, the best end of the neck of mutton, or the middle, if divested of a large portion of the fat and cut into good shape, will furnish one of appropriate size and of excellent quality. Let the ends be cut quite even and the bones short, so as to give a handsome squareness of form to the meat. The butcher, if directed to do so, will chop off the chine bone, and divide the long

bones sufficiently at the joints to prevent any difficulty in separating them at table. From four to five pounds weight of the neck will require from an hour to an hour and a quarter of roasting at a clear and brisk, but not _fierce_, fire. It should be placed at a distance until it is heated through, and then moved nearer, and kept _thoroughly basted_ until it is done. Tomatas baked or roasted may be sent to table with it; or a little plain gravy and red currant-jelly; or it may be served without either.

When the entire joint, with the exception of the scrag-end (which should always be taken off), is cooked, proportionate time must be allowed for it.

TO ROAST A SHOULDER OF MUTTON.

Flour it well, and baste it constantly with its own dripping; do not place it close enough to the fire for the fat to be in the slightest degree burned, or even too deeply browned. An hour and a half will roast it, if it be of moderate size. Stewed onions are often sent to table with it. A shoulder of mutton is sometimes boiled, and smothered with onion sauce.

1-1/2 hour.

THE CAVALIER'S BROIL.

Half roast or stew, or parboil, a small, or moderate-sized shoulder of mutton; lift it into a hot dish, score it on both sides down to the bone, season it well with fine salt and cayenne or pepper, and finish cooking it upon the gridiron over a brisk fire. Skim the fat from any gravy that may have flowed from it, and keep the dish which contains it quite hot to receive the joint again. Warm a cupful of pickled mushrooms, let a part of them be minced, and strew them over the broil when it is ready to be served; arrange the remainder round it, and send it instantly to table. The reader will scarcely need to be told that this is an excellent dish.

FORCED SHOULDER OF MUTTON.

Cut off all the flesh from the inside of the joint down to the blade-bone, and reserve it for a separate dish. It may be lightly browned with some turnips or carrots, or both, and made into a small harrico or stewed simply in its own gravy, or it will make in part, a pie or pudding. Bone the mutton (see page 219), flatten it on a table, lay over the inside some thin and neatly-trimmed slices of striped bacon, and spread over them some good veal forcemeat (No. 1, Chapter VIII.) to within an inch of the outer edge; roll the joint up tightly towards the knuckle (of which the bone may be left in or not, at pleasure), secure it well with tape or twine, and stew it gently in good gravy, from four hours to four and a half.

4 to 4-1/2 hours.

Obs.—In France it is usual to substitute _sausage-meat_ for the bacon and veal stuffing in this dish, but it does not appear to us to be well suited to it.

MUTTON CUTLETS STEWED IN THEIR OWN GRAVY.

(_Good._)

Trim the fat entirely from some cutlets taken from the loin; just dip them into cold water, dredge them moderately with pepper, and plentifully on both sides with flour; rinse a thick iron saucepan with spring water, and leave three or four tablespoonsful in it; arrange the cutlets in one flat layer, if it can be done conveniently, and place them over a very gentle fire; throw in a little salt when they begin to stew, and let them simmer as _softly as possible_, but without ceasing, from an hour and a quarter to an hour and a half. If dressed with great care, which they require, they will be equally tender, easy of digestion, and nutritious; and being at the same time free from everything which can disagree with the most delicate stomach, the receipt will be found a valuable one for invalids. The mutton should be of good quality, but the excellence of the dish mainly depends on its being _most gently stewed_; for if allowed to boil quickly all the gravy will be dried up, and the meat will be unfit for table. The cutlets must be turned when they are half done: two or three spoonsful of water or gravy may be added to them should they not yield sufficient moisture; or if closely arranged in a single layer at first, water may be poured in to half their depth. The advantage of this receipt is, that none of the nutriment of the meat is lost; for that which escapes from the cutlets remains in the gravy, which should all be served with them: any fat which may be perceived upon it should be carefully skimmed off. Cold broth used for it instead of water will render it extremely good.

1-1/4 to 1-3/4 hour.

TO BROIL MUTTON CUTLETS. (ENTRÉE.)

These may be taken from the loin, or the best end of the neck, but the former are generally preferred. Trim off a portion of the fat, or the whole of it, unless it be liked; pepper the cutlets, heat the gridiron, rub it with a bit of the mutton suet, broil them over a brisk fire, and turn them often until they are done; this, for the generality of eaters, will be in about eight minutes, if they are not more than half an inch thick, which they should not be. French cooks season them with pepper and salt, and brush them lightly with dissolved butter or oil, before they are laid to the fire, and we have found the cutlets so managed extremely good.

Lightly broiled, 7 to 8 minutes. Well done, 10 minutes.

Obs.—A cold Maître d'Hôtel sauce may be laid under the cutlets when they are dished; or they may be served quite dry, or with brown gravy; or with good melted butter seasoned with mushroom catsup, cayenne, and chili vinegar or lemon-juice.

CHINA CHILO

Mince a pound of an undressed loin or leg of mutton, with or without a portion of its fat; mix with it two or three young lettuces shred small, a pint of young peas, a teaspoonful of salt, half as much pepper, four tablespoonsful of water, from two to three ounces of good butter, and, if the flavour be liked, a few green onions minced. Keep the whole well stirred with a fork over a clear and gentle fire until it is quite hot, then place it closely covered by the side of the stove, or on a high trivet, that it may stew as softly as possible for a couple of hours. One or even two half-grown cucumbers, cut small by scoring the ends deeply as they are sliced, or a quarter of a pint of minced mushrooms may be added with good effect; or a dessertspoonful of currie-powder and a large chopped onion. A dish of boiled rice should be sent to table with it.

Mutton, 1 pint; green peas, 1 pint: young lettuces, 2; salt, 1 teaspoonful; pepper, 1/2 teaspoonful; water, 4 tablespoonsful; butter, 2 to 3 oz.: 2 hours. Varieties: cucumbers, 2; or mushrooms minced, 1/4 pint; or currie-powder, 1 dessertspoonful, and 1 large onion.

A GOOD FAMILY STEW OF MUTTON.

Put into a broad stewpan or saucepan, a flat layer of mutton chops, freed entirely from fat and from the greater portion of the bone, or in preference a cutlet or two from the leg, divided into bits of suitable size, then just dipped into cold water, seasoned with pepper, and lightly dredged with flour; on these put a layer of mild turnips sliced half an inch thick, and cut up into squ

OF

HATS AND CAPS.

BY M. ELLIOTT,

(_Needlework Correspondent to The “Queen” Newspaper._)

Dedicated by permission to the Lady Marion Alford.

WHOLESALE ONLY OF FAUDEL, PHILLIPS & SONS, _NEWGATE STREET, LONDON_.

RETAIL AT ALL BERLIN REPOSITORIES.

Entered at Stationers’ Hall.

FAUDEL, PHILLIPS & SONS,

Manufacturers of all kinds of

Embroidery and Sewing Machine Silks.

FILOSELLES IN 400 SHADES.

Knitting and Crewel Silks in great variety.

Fast-dyed Embroidery Silk for Outlining.

THE PEACOCK ICE SILK

[Illustration: REGISTERED

ICE SILK

TRADE MARK]

Is one of the most successful materials ever made, it DOES NOT CHAFE in working, and after considerable wear RETAINS ITS SILKY CHARACTER.

It is well adapted for Socks, Stockings, Shawls, Vests, Ties, Gloves, &c., &c.

It is made in two sizes, two-fold and four-fold; the two-fold being more suitable for Crochet purposes, can also be used for Ladies’ fine Hose.

LIST OF SHADES IN STOCK (_four-fold_)

Black White Cream Grey Drab Old Gold Buff Bronze Prune Seal Brown Pale Blue ” ” No. 2 Light Blue Azuline Blue Royal ” Navy Flesh Salmon Pink Coral Crimson Cardinal Scarlet Ruby Violet

TWO-FOLD.—Pale Blue, Pale Blue 2, Light Blue, Azuline, Royal, Navy, Grey, Buff, Flesh, Old Gold, Prune, Pink, Coral, Cardinal, Scarlet, Ruby, Cream, White and Black.

Put up in Half-ounce Balls. Boxed One Dozen Balls of a Shade.

The qualities and sorts mentioned in the following instructions are of the very best kind and make, and eminently suitable for all Knitting and Crochet purposes.

Besides these, there are other qualities and makes of Peacock Brand, as—

Extra Fleecy. B. do. M. do. Pyrenees. Welsh. B. Shetland. B. Andalusian. B. Eider. D. Shetland. D. Andalusian. German Yarn. Bicycling Yarn. Arabian Yarn. Petticoat Fleecy Wool. Royal 60-turn Fingering. Princess' Knitting Yarn.

All of these are made from good quality Wool, are full value at their prices, and give great satisfaction: still, the PEACOCK QUALITIES are universally admitted to be superior to any other, and they were _Highly Commended_ and obtained a Certificate at the Sydney International Exhibition in 1879, in spite of the very large and extensive exhibits of numerous other makes and brands, all of which were deemed inferior.

Ladies should be most particular to procure Peacock Qualities, or qualities under Peacock Brand if they desire their work to be of a superior kind.

WHOLESALE ONLY AT FAUDEL, PHILLIPS, & SONS', 36, 37, 38, 39, & 40, NEWGATE STREET, LONDON.

In presenting this book to the Public of useful Knitted and Crochet Articles, I wish to give a few suggestions with regard to the Wools used and the mode of washing them.

No Wool is so cheap as the best. It is false economy (I have tested it constantly) to work with inferior Wools. From a very long and tried experience I have the greatest confidence in fully recommending Peacock Qualities; they are full measure, and extra good. If washed according to the directions I give, and not washed oftener than necessary, I have no doubt of their wear. Little children's knitted garments should always be washed in the nursery, or at home. The following is an admirable method; but, where it can be done, all Knitting and Crochet should be "blocked" to dry. The "block" is a piece of evenly-planed hard wood—generally box-wood—cut the size and shape of the garment. In some cases the blocks are earthenware. Little feet, and models of children's legs and feet, can be procured in nearly all sizes. The work, when washed and wringed, but not wrung, must be drawn on the blocks and left to dry quickly in a warm place.

TO WASH WOOL.

All fine Shetland, or other finely-combed and spun Wools, should be washed in a lather of bran—_no_ soap, unless very dirty. A gallon of boiling water should be poured over 1 lb. of bran, and the two stirred well together in a boiling state for five or six minutes; leave it in a pancheon or basin all night; in the morning pour off the water, make it lukewarm, wash your work in it, then rinse in lukewarm clean soft water and block till dry. Where you have not a block, cover a board with a clean cloth and pin the work out to dry. If the work is much soiled, take a little transparent soap (it is the most free from all injurious matters), mix into a lather in a little warm water, and gently wash the work in the lather (on no account rub the work with soap), rinse in cold water, and block.

_No. 1._

[Illustration: Tam o’Shanter cap]

TAM O’SHANTER CAP.

Knitted, for a Man.

You require 2 ozs. Navy Blue Eider Wool, ½ oz. Scarlet Single Berlin for the Tuft, 9 needles, No. 15 for a very tight knitter, No. 16 for a loose knitter. The cap knitted by these directions measured 12 stitches to the inch, laid perfectly flat, with no stretching whatever.

Cast 4 stitches on to one needle. Knit these off on to 4 separate needles, using a 5th, and work in rounds.

1st row—Knit plain.

2nd row—Knit 2 stitches on each of the 4 needles. You work these by knitting 2 in each stitch: knit the stitch, and before taking it from the left needle put the right needle between the two threads on the left needle, take up the back part and knit a stitch on it. All the increasings in the work are made in this manner.

3rd row—Knit plain.

4th row—Increase in the first stitch on each needle.

5th row—Knit plain. Repeat these two rows twice more.

10th row—Increase in every 3rd stitch.

11th, 12th and 13th rows—Knit plain. Repeat these 4 rows 3 more times.

26th row—Increase in every 4th stitch.

27th, 28th, 29th and 30th rows, plain. Repeat these 5 last rows 4 times.

51st row—Increase in every 5th stitch.

52nd and 4 next rows—Knit plain. Repeat from the 51st row 5 more times.

86th row—Increase every 6th stitch. In this round mark the beginning of the round with some white thread, as it is essential to keep the rows distinct. You will have to take more needles as they fill. 7 rounds plain.

94th round—Increase every 7th stitch.

95th and 7 next rounds plain.

103rd round—Increase every 8th stitch.

104th and next 8 rounds plain.

113th round—Increase every 9th stitch. Knit 10 rounds plain.

124th round—Increase every 10th stitch. 10 rounds plain.

134th round—Increase every 11th stitch. 20 rounds plain.

164th round—Decrease by knitting 2 together every 11th and 12th stitches. 10 rounds plain.

175th round—Knit together every 10th and 11th stitches. 9 rounds plain.

185th round—Knit together every 9th and 10th stitches. 9 rounds plain.

193rd round—Knit together every 8th and 9th stitches. 8 rounds plain.

201st round—Knit together every 7th and 8th stitches. 7 rounds plain.

208th round—Knit together every 6th and 7th stitches. 6 rows plain.

You now rib in alternate stitches of knit 1, purl 1, knitting each stitch from the back of the loop, 30 rows, and cast off.

The work must now be flattened, and shaped. Cut a round of stiff cardboard slightly larger than the work, put the work on the board and damp it, leave it on the board until it is quite dry. You line it with thin silk, and add the tuft.

The Tuft is made by winding the scarlet wool over card. Take a piece of card, 1½ in. wide—it must be smooth and strong—double over it a piece of fine wire the length of the card. Over the wire and the card wind the wool until the whole is wound, take the ends of the wire and twist the wool firmly and strongly together with it, slip the wool off the card; this makes a firm, compact tuft. You cut the top open, cut it level with sharp scissors, and sew into the middle of the hat.

_No. 2._

TAM O'SHANTER in Crochet.

Work with two contrasting colours of the Peacock A. A. Fingering, one skein of each, and a fine bone crochet hook, No. 12. Make a chain of 8, with one colour only, unite.

2nd row—Work in double crochet.

3rd row—Work 2 double crochet in every stitch.

4th row—Work each stitch in alternate colours, passing the wool at the back from one to the other, and increase in every 3rd stitch.

5th row—Plain.

6th row—Increase every 3rd stitch.

7th and 8th rows—Plain.

9th row—Increase every 3rd stitch.

10th and 3 next rows—No increasings. Repeat these 5 rows 5 more times.

34th row—Increase every 6th stitch. 4 rows plain. Repeat these 5 rows until your work measures 16 inches across, work 10 more plain rounds, and from that round begin to decrease every 6th stitch. This is done by taking up the 1st on the needle, then the 2nd, and working the two as one. Four rounds plain; repeat these 5 rounds until your work from the last of the 10 plain rounds measures 4½ inches. You then take up the stitches on 5 knitting needles, and knit 20 rounds, with one colour only, of 1 purl, 1 plain, and cast off.

The Cap should be lined, and a tuft made in the same manner as directed in the receipt for a Knitted Cap.

_No. 3._

[Illustration: Jack Tar cap]

JACK TAR, for a Man.

In imitation of Plush.

In some of our shops this shape is wrongly sold as the Tam O'Shanter; that shape is much larger, and the _under_ part much deeper than the Jack Tar.

This Cap has a very soft appearance, and is light and warm. For a fancy dress use light pink, blue, or cream; for general winter wear, maroon or dark grey. You will require 5 oz. of Peacock Fingering and a No. 12 hook: about the same quantity of Peacock Lady Betty, and more if Fleecy is used. If the work is _combed_ after it is finished, the Fleecy should be used, as it wastes the wool.

Make a chain of 40 stitches.

1st row—Double crochet.

2nd row—Put the hook in the 1st stitch, wind the wool over the hook and round the 1st finger of the left hand twice, draw the loops on the needle through the double crochet loop, and finish as usual. Work the whole row in this manner.

3rd row—Turn and work in single crochet.

These two rows are worked throughout; repeat them twice more. They will be called _one_ row in the remainder of the directions.

6th row—Work 8 stitches, turn, work back.

7th row—Work 8, and 4 more on the last long row, turn, work back.

8th row—Work 12, and 4 more, turn, work back. Work in this manner until all are raised, then work 3 more whole rows, working the 40 stitches. Repeat from the 6th row until the work lies flat on the table and meets easily. You will have to repeat it 9 more times according to some workers, perhaps more with a tight worker. When the top is finished and joined together, you work round the outside edge of the work 6 rounds of loop crochet, work round and round, and work 1 stitch on the stitch of the preceding row, always taking up the two edges of the stitch.

You now decrease for the under rim; this is not very wide, the whole depth not being more than 1 inch. If the hat is being made as a special fit, take the measure of the head, then measure the work, and decrease gradually to the exact size; 6 rows of decreasings only are required. For an ordinary hat, work for 6 rounds every 5th and 6th stitches as one. After these rounds, you work 12 rounds of plain double crochet for the head. The name of the wearer or a ship should be crocheted into the band.

The letters should be drawn out on a piece of point paper; this is divided into little squares 1-16th of an inch in size. Then you take a coloured wool; each square represents a stitch, the letters are worked in red or gold, in double crochet, by simply passing the wool used as the ground at the back of that used for the letters. It makes a better effect to work the letters by putting the needle into the stitch, pull the wool through, the wool on the needle, put the needle into the same stitch again, and draw through the wool on the needle and through all the loops on the needle. This stitch raises the work.

You must next cut the loops of wool open and trim them neatly with a sharp pair of scissors, and you have an exact imitation of fur.

The crochet work of the hat is now finished. Quilt a lining and sew in the head. Cut a piece of lining muslin, 3 doubles, for the brim (or a piece of leather), sew inside the 12 rows of crochet for the head, and add strings at the back.

A tassel of silk is made in the same way as the tuft, and placed in the middle of the crown.

_No. 4._

[Illustration: Dundee Bonnets]

DUNDEE BONNET.

Knitted in red and black Victoria yarn, or any other mixture; black Head-piece in crochet; a crochet-hook, No. 14.; six needles, No. 14.

Make a chain with the crochet-hook, working rather tightly, that will measure 22 inches. On this work a row of single crochet, thus, * the needle in the next stitch, draw the wool through and through the loop on the hook; repeat from *, at the end of the chain join to the first double crochet. On this foundation work very tightly, 12 rows of crochet. Work each row with the same stitch.

1st row of Head-piece—The wool on the needle, insert in the next stitch; draw the wool through, and then through the three stitches on the needle. When the 12 rows are finished, take up all the stitches on five knitting needles, an equal number on each; knit with the sixth. The 1st needle is the first half of the back; the 2nd, the side; the 3rd, the front; the 4th needle, the second side; the 5th, the last half of the back. Knit plain to the middle of the 4th needle, turn, purl the stitches to the middle of the 2nd needle, turn, slip the first, * knit 1, purl 1; repeat from * to the middle of the 4th needle, and increase in every 8th stitch; knit 4 stitches less on the 4th needle than you did before, * turn, purl the purled stitch of last row, knit the knitted, and leave 4 less at the end of this half-round. Repeat from *, increasing every 7th stitch in every 3rd row, and leaving 3 stitches instead of 4, as in the first repetition, then 2

stitches each repetition, until you have one quarter of the stitches left on the 3rd needle. You must now work all these stitches, and, as you take up each set of two, work an extra one on the side of the last, between it and the first of the two next; knit the whole round, increasing on the remainder of the 4th, 5th, 1st and 2nd needles, every 6th stitch. Work the increasings by knitting 2 in one stitch, as directed in the pattern, No. 1.

You must now knit in rounds, and increase every alternate round in the 6th stitch until the knitting at the back measures 1½ inches above the band. The front must be 5½ inches deep; it will require some more shaped rows, therefore, before you work the last 6 rounds of the back. Work on the 2nd, 3rd and 4th needles as many more half-rows, repeating the directions, until you have the right depth.

You now work the 6 rounds to finish the Head-piece, increasing every 6th stitch in _each alternate round_.

You next work 18 rounds with no decreasings; then decrease for the crown.

The knitting, according to the work from which this is written, measured 36 inches in circumference. Make a decreasing every 16th and 17th stitch by knitting those two stitches together; the 2nd and 3rd rounds no decreasings. Knit in this manner until there are only 10 stitches on the needle, cast these off with a row of double crochet, make a rosette, and place in the centre; add ribbons behind. Line the head with silk, and the band with thin leather or double linen.

_No. 5._

[Illustration: Bicycling Or Patrol Cap]

BICYCLING OR PATROL CAP.

Crocheted with Andalusian wool, and a fine bone crochet hook; a knot of fine mohair cord, or very fine black bobbin cord; the former is the best for use. The whole of the crochet is worked over this cord, which gives a raised appearance, and makes the shape better.

Make a chain of 4, unite, draw the cord through the chain, loop it securely over the cord and chain; work 8 double crochet. The cord must, throughout the work, be held in its place by the finger and thumb of the left hand, keeping it at the edge of the row, underneath and behind the needle.

2nd round—In the 8 double crochet work 16 treble. Take up all the stitches through _both_ loops, or your work will not have the ribbed appearance it should have.

3rd round—Work 2 treble in every stitch.

4th and successive rounds—Work round and round, increasing to keep the work flat, until you have 15 rounds. You now commence the band round the hat. In the first round you must slightly tighten together the cord, as well as in succeeding rounds, to keep it the right shape; work 9 rounds for this head-band, and finish with 2 of double crochet. You then line with black linen, and sew in a piece of leather. Work a small round of crochet to cover a button for the centre, and make a crochet rosette to go round it.

The Rosette.

Make a chain of 8, unite.

In this work 1 chain, 1 double crochet, 8 times.

2nd round—1 double crochet in the first chain, *2 treble on the double crochet, 1 double crochet in the next chain; repeat from *.

3rd round—1 double crochet on the double crochet, * 5 treble on the 2 treble, 1 double crochet on the next double crochet, repeat from *. Take the cord and work it round the next row.

4th round—* 1 double crochet on the double crochet, 2 treble on the 1st treble, 1 long on the 2nd, 2 double long on the 3rd, 1 long and 1 treble on the 4th, 1 treble on the 5th; repeat from *.

6th round—1 single on each stitch of last row. This is laid on the middle of the hat and the button placed in the centre.

_No. 6._

TARBUCH

In black netting silk and gold thread.

The Tarbuch is taken from one worked in Egypt, and is the correct shape. It is worked with very fine purse silk, twelve skeins; Japanese or Chinese gold thread, the finest size, wind this in balls; a fine crochet hook. The pattern consists of a star in the centre of the crown: this star has 10 divisions, a border of vine leaves round the edge, and powdered ground.

Commence the crown with black silk, with a chain of 4, unite; in this work 10 double crochet.

2nd round—In every stitch of last round work 1 black and 1 gold. In working with two colours you should knot the two threads together in beginning, and throughout the work hold both evenly over the same finger of the left hand, then, as you proceed, keep the thread _not_ in use in regular rotation over and under the thread in use; by this means you work them in. Care must be taken _never_ to completely finish a stitch with the one colour; if it _is_ done you have _two_ stitches of the colour and throw the pattern wrong. In this 2nd round put the needle into the stitch, draw through the _black_ silk, take up the _gold_ and finish the stitch; take up the next stitch with gold, finish it with black. You have now two distinct stitches.

3rd round—1 black on the black, 2 gold on the 1 in last round.

4th round—1 black on the black, 3 gold on the 2 in the last round.

5th round—1 black on the black, 4 gold on the 3 underneath.

6th round—1 black on the black, 5 gold on the 4 underneath.

7th round—1 black on the black, 6 gold on the 5 underneath.

8th round—1 black on the black, 7 gold over the 6.

9th round—1 black on the black, 8 gold over the 7.

10th round—1 black on the black, 9 gold over the 8.

11th round—1 black on the black, 10 gold over the 9.

12th round—1 black on the black, 11 gold over the 10.

13th round—1 black on the black, 12 gold over the 11.

14th round—1 black on the black, 13 gold over the 12.

15th round—1 black on the black, 14 gold over the 13.

16th round—1 black on the black, 15 gold over the 14.

17th round—2 black on the 1st black, * 14 gold over 14 gold, 1 black on the 15th, 2 black on the next black; repeat from *.

18th round—5 black over the 3 black, 13 gold over 13 gold.

19th round—Care must be taken to make the gold begin exactly on the same stitch in each division, as the right-hand side of each must be even, one less worked each row on the left side. 3 black, 1 gold, 3 black over the 3 black and the last gold; 12 gold over the 12 gold.

20th round—Over the 13th gold and 7 black work 9 black, 11 gold over 11.

21st round—10 gold over 10, on the last gold and the black work 11 black.

22nd round—9 gold over 9, 2 black, 1 gold, 7 black, 1 gold, 2 black, over the 11 and last.

23rd round—8 gold over 8, 15 black over the 13 black and 1 gold.

24th round—7 gold over 7, 17 black over the 15 and last gold.

25th round—6 gold over 6, 9 black, 1 gold, 9 black over the black.

26th round—5 gold over 5, 21 black over the black.

27th round—4 gold over 4, 23 black over 21 underneath.

28th round—3 gold over 3, 8 black, 1 gold, 7 black, 1 gold, 8 black, over the black.

29th round—2 gold over 2, 27 black.

30th round—1 gold over 1, 30 black.

31st round—On the point of the star (the one gold stitch) work 2 with black; on the next black work 7 black, 1 gold, 7 black, 1 gold, 7 black, 1 gold, 7 black; then repeat with 2 on the next gold.

32nd round—Between each point increase 3 stitches, and work entirely with black.

33rd round—Black, and no increasings.

34th round—You work 1 gold exactly between the 1st gold stitch in the 31st round and the point, then 7 black, 1 gold, repeating all round.

35th and 36th rounds—Black; repeat from 34th round 5 more times. In the last plain row work an extra stitch every 23rd stitch.

52nd round—* 8 black, 1 gold, 7 black, 1 gold, 7 black, 1 gold, 7 black, 1 gold; repeat from *.

53rd and 54th rounds—Repeat these 3 rounds twice more; increase until you have 360 stitches, which will bring you to the part for the border. Work a row of black double crochet, and begin

The Border.

1st round—2 black, 3 gold, * 12 black, 3 gold, repeat from *; end the round with 10 black.

2nd round—6 gold, 8 black, * 7 gold, 8 black, repeat from *; end the round with 1 gold.

3rd round—4 black, 3 gold, * 4 black, 4 gold, 4 black, 3 gold, repeat from *, and end the round with 4 gold.

4th round—* 7 gold, 3 black, 3 gold, 2 black, repeat from *.

5th round—2 gold, * 4 black, 1 gold, 3 black, 2 gold, 1 black, 4 gold, repeat from *, and end the round with 2 gold.

6th round—1 gold, * 7 black, 3 gold, 1 black, 4 gold, repeat from *; end the round with 3 gold.

7th round—* 8 black, 2 gold, 1 black, 4 gold, repeat from *.

8th round—* 9 black, 4 gold, repeat from *, and end the round with 2 black.

9th round—* 5 gold, 2 black, 2 gold, 1 black, 2 gold, 3 black, repeat from *.

10th round—1 gold, * 3 black, 3 gold, 6 black, 3 gold, repeat from *; end the row with 2 gold.

11th round—* 6 black, 3 gold, 2 black, 3 gold, 7 black, repeat from *, and end the round with 1 black.

12th round—* 2 gold, 1 black, 2 gold, 3 black, 4 gold, 2 black, 3 gold, 1 black, repeat from *; end round with 1 gold.

13th round—3 black, 4 gold, * 11 black, 4 gold, repeat from *, and end with 8 black.

14th round—1 black, * 2 gold, 1 black, 4 gold, 8 black, repeat from *, and end with 7 black.

15th round—1 black, 3 gold, * 1 black, 4 gold, 7 black, 3 gold, repeat from *; end the round with 6 black.

16th round—3 black, * 2 gold, 2 black, 3 gold, 4 black, 1 gold, 3 black, repeat from *, and end the round with 1 gold.

17th round—3 black, 4 gold, * 2 black, 6 gold, 3 black, 4 gold, repeat from *; end with 1 gold.

18th round—* 4 black, 5 gold, 3 black, 3 gold, repeat from *.

19th round—7 black, * 7 gold, 8 black, repeat from *.

20th round—10 black, * 4 gold, 11 black, repeat from *, and end the round with 1 black.

21st, 22nd and 23rd rounds—Black.

24th round—* 7 black, 1 gold, repeat from *.

25th round—* 5 black, 3 gold, repeat from *.

26th and 27th rounds—Gold only, and fasten off.

This completes the Cap. It should, properly speaking, be put upon a block; this may be made of cardboard. Line the Cap through with a blue satin lining, gathering it in at the top and sew over neatly with a large button covered with satin. This must not be sewn in until the tassel is passed through.

The Tassel.

Wind the netting silk round a piece of cardboard 5 inches long, wind a sufficient quantity to make it look handsome. Under the silk pass a doubled length, and tie it all together very tightly, slip it off the card, and wind two thicknesses of silk firmly over the tied end for the depth of three-quarters of an inch, leave an end about half a yard long, thread a strong needle with this end, pass it through the tassel, under the silk wound over, and bring the needle out at the top; make a firm chain of about 2 inches long with this silk.

You next crochet a covering for the top of the tassel. This is worked in double crochet. Begin with 5 chain, work 7 double crochet on it, on the 7 double crochet work 10, on the 10 work 14, and increase until it will fit tightly over the silk you have wound over; work the depth to cover the winding, sew it down strongly. Pass the chain through the foundation chain of the cap, and sew very securely.

_No. 7._

[Illustration: Fisherman’s Cap]

FISHERMAN’S CAP, for a Man.

One oz. of dark red, one oz. of gold wool.

These Caps should be knitted in stripes to suit the Jersey, jacket, or shirt of the wearer. They are knitted in Merino wool, or 2-fold Ice silk, on No. 17 needles. On a Lamb’s knitting machine use the finest red silk; knit the Cap the full length in stripes; then, on each side and in the middle, decrease until you come to a point; sew this together, and the hat is made.

To knit the Cap with the wool or silk named, cast on on 4 needles 260 stitches with red wool, knit 16 rounds; change, take the gold, knit 16 rounds. Knit 16 stripes in this manner, 8 of red, 8 of gold, then begin to decrease for the top.

Black stripe—Knit 2, knit 2 together, knit 57, knit 2 together, knit 4, knit 2 together, knit 57, knit 2 together, knit 4, knit 2 together, knit 57, knit 2 together, knit 4, knit 2 together, knit 57, knit 2 together, knit 2.

Knit 3 rounds plain.

5th round—Knit like the first row in the black stripe, but with 55 stitches between, instead of 57. Work in this manner, with 3 plain rounds between each round of decreasing, until you have 41 stitches between each set of decreasings, then decrease every 3rd round until you have only 27 on the needle between the decreasings; after that, decrease every alternate round until the decreased stitches come close together; you then * knit 2, knit 2 together, all round; repeat from *. In the next round knit 1, * knit 3 together, knit 2, repeat from *; then decrease by knitting 2 together every stitch until you have a point. Make a tassel of the two colors, and sew on to the point. Hem up the foundation round inside the work, folding the knitting evenly in the middle of the third black stripe.

* * * * *

This Cap can, of course, be knitted in any material; the finer the wool, the more suitable. The size must be determined by measuring the head; knit a small piece of knitting of 20 stitches square with the materials you intend to use, and measure this with a tape measure. A simple multiplication of the number of stitches you have in an inch will enable you at once to cast on the required number of stitches, then work as directed. A very handsome Cap is made by using a combination of colors. Commence with black, ¼-inch, 3 rounds of red, 1 of gold, 2 of blue, 1 of gold, 2 of red, 3 of gold, 2 of red, 1 of gold, 5 of blue, 1 of gold, 2 of red, 3 of gold, 2 of red, 1 of gold, 2 of blue, 1 of gold, 3 of red, 20 of black, then commence the red again for one or two more stripes, and work the remainder of the Cap in one color, or continue it in stripes.

_No. 8._

[Illustration: Football Cap]

CAP, TURBAN-SHAPE, FOR FOOTBALL, Etc.

Crocheted with Japanese Silk, using black and gold, or any of the colours required for clubs. You require a ball of gold Japanese silk, one of black, a steel crochet needle, No. 12.

With the black make a chain of 3, unite, work round and round, increasing to keep flat, until you have 32 stitches.

Take the gold silk, work 2 rounds of double crochet; turn.

3rd round—In the 1st stitch work * 2 double crochet, 1 in the 2nd, take up the 2nd double crochet in the 1st of these 3 rounds, work 4 treble in it, join the 1st and 4th of these long stitches together by a single; repeat from *. Work 2 stitches in every stitch after the treble stitches.

4th and 5th rounds—Black, double crochet, increasing to keep the work flat.

6th and 7th rounds—Gold silk, double crochet, increasing as necessary.

8th round—Like the 3rd round. Work in this manner until you have 7 rounds of raised work, which will make the cap the right shape; it should be 6½ to 7 inches in diameter. Then continue the same with no decreasings for the band round the head; you require 4 rows of patterns for this. Finish the work with 2 rounds of black silk. Line the cap, add a piece of leather round the edge, and put a button, covered with double crochet worked in gold silk, in the centre.

For a Smoking Cap this shape, add a silk tassel, to hang down over the side.

_No. 9._

FOOTBALL CAP.

Crocheted in Japanese Silk or Eider Wool; Crochet hook, No. 12; 3 balls of silk, or 1½ oz. of wool.

Make a chain of 3, unite, in this work 6 double crochet.

2nd round—Work 12 double crochet.

3rd round—* Insert the needle in the next stitch, draw the thread through the thread round the needle, draw through the same loop again, the thread on the needle, draw through all the loops on the needle; repeat from * for each stitch. Work the round, and make 2 stitches in every 3rd stitch of the round underneath.

4th round—Work the same stitch as last round, and in each successive round, but work _between_ the stitches of the previous round. The work must be kept rather tight. Increase every 5th stitch.

5th round—No increasings.

Work in this manner, increasing gradually, until the work is nearly 7 inches across. This will allow the size to be just under 21 inches; about 22½ is a usual size in hats. The brim of the hat is increased very gradually indeed. Work 4 rounds with no increasings; in the next, divide the work into quarters; work an extra stitch in beginning each quarter; and do the same every 3rd round, which will give the brim the desired slope. When you have worked the top, work round and round, with no increasings, for 6

rounds; then take the contrasting colour and work 1½ inches of it; fasten off. Work another small round of the same stitch in this colour, cover a large button or curtain ring with it, and place at the top of the cap. Line the crown and sides with black silk, and sew a piece of leather, 3 inches deep, round the rim.

Transcriber’s Notes

pg 18 Changed an unknown symbol to an asterisk at beginning of line: * knit 1, purl 1; repeat from * to the middle of the 4th needle

pg 23 Changed: knot the two threads together in begining to: knot the two threads together in beginning

Whether you are just learning the skills of food management and good cooking or are an experienced hand in the kitchen, this booklet—prepared by USDA food and nutrition scientists—can serve you well.

It combines good eating and good nutrition. It packs the results of years of food and nutrition research into a ready handbook for everyday use. It tells how to get the nutrients you need from a variety of foods—then translates this knowledge into taste-tested recipes and well-balanced meals.

Feeding your family well takes less time and work than it used to. Today’s foods can have built-in convenience. Meals can be more varied because more food choices are available.

* * * * *

In this publication you’ll find—

• A daily food guide—a simple, workable presentation of the kinds and amounts of foods to have each day.

• Tips on meal planning.

• Helpful information on buying, storing, measuring, and using foods.

• A selection of recipes—main dishes, vegetables, salads, soups, sauces, breads, sandwiches, desserts—plus variations of some of these recipes.

• Menu suggestions.

• A list of cooking terms.

NUTRITION....

Food At Work For You

Nutrition is the food you eat and how the body uses it.

People differ in how much they want to know about nutrition, but everyone needs to know a few facts about food and health as a basis for selecting the foods to eat.

You need food to get energy for work and play, to move, to breathe, to keep the heart beating—just to be alive. Children and youths need energy from food for growth.

Food also provides a variety of substances—nutrients—that are essential for the building, the upkeep, and the repair of body tissues, and for the efficient functioning of the body.

Everyone needs the same nutrients throughout life but in different amounts. Proportionately greater amounts are required for the growth of a body than just for its upkeep. Boys and men need more energy and nutrients than girls and women. Large people need more than small people. Active people require more food energy than inactive ones. People recovering from illness need more than healthy people.

You and your family can get all the nutrients you need from foods, but no one food contains all the nutrients in the amounts required for growth and health. Only a variety of different kinds of foods will supply all you need.

A guide to eat by

Nutrition scientists have translated knowledge of the nutrient needs of people and the nutritive values of foods into an easy-to-use guide for food selection.

This Daily Food Guide, on pages 4 and 5, sorts foods into four groups on the basis of their similarity in nutrient content. Each of the broad food groups has a special contribution to make toward an adequate diet.

Here are some of the reasons different food groups are emphasized in the guide and the names of some of the nutrients these foods provide.

Meat, poultry, fish, and eggs from the _meat group_ and their alternates—dry beans, dry peas, and nuts—are valued for their protein. This is needed for the growth and repair of body tissues—muscle, organs, blood, skin, and hair. These foods also contribute iron and the B-vitamins—thiamine, riboflavin, and niacin.

Vegetables and fruits from the _vegetable-fruit group_ are valuable sources of vitamins and minerals. In the guide, this group is counted on to supply most of the vitamin C and a large share of the vitamin A value in the diet. Choices are directed toward the citrus fruits and some other foods that are among the better sources of vitamin C; and toward the dark-green and deep-yellow ones for vitamin A value.

Vitamin C is needed for healthy gums and body tissues. Vitamin A is important for growth, normal vision, and a healthy condition of the skin and other body surfaces.

Foods from the _milk group_ are relied on to meet most of the calcium needs for the day. Milk is the leading source of the mineral calcium, which is needed for bones and teeth.

Milk also provides protein, riboflavin, vitamin A, and many other nutrients. Cheese and ice cream also supply these nutrients, but in different proportions.

The _bread-cereal group_, with its whole-grain and enriched bread and other cereal products, furnishes important amounts of protein, iron, several of the B-vitamins, and food energy.

Fats, oils, sugars, and sweets are not emphasized in the guide because they are common in every diet. Some of the fats and oils provide certain of the vitamins, and some furnish essential fatty acids, but the chief nutritional contribution of these foods is energy value.

How to use the guide

Homemakers who follow the guide will find it flexible enough to use in choosing foods for families.

Food choices within the groups are wide enough to allow for a variety of everyday foods. Meals can be planned to include family favorites, foods in season, and foods to fit the family budget.

The size of servings can be suited to the needs of family members—small servings for children and for those wanting to lose weight; extra large servings (or seconds) for very active adults, teenagers, and those wanting to gain weight. Pregnant and nursing women also need more food.

Foods from the Daily Food Guide fit easily into a three-meals-a-day pattern of eating. Foods from each group often appear in each meal—but this isn't essential. The important thing is that the suggested number of servings from each food group be included sometime during the day.

Many people want and need more food than the minimum servings suggested from the four food groups. To round out meals and satisfy appetites, you can include additional foods from the four groups as well as other foods not listed in these groups.

A Daily Food Guide

MEAT GROUP

Foods Included

Beef; veal; lamb; pork; variety meats, such as liver, heart, kidney.

Poultry and eggs.

Fish and shellfish.

As alternates—dry beans, dry peas, lentils, nuts, peanuts, peanut butter.

Amounts Recommended

Choose 2 or more servings every day.

Count as a serving: 2 to 3 ounces of lean cooked meat, poultry, or fish—all without bone; 2 eggs; 1 cup cooked dry beans, dry peas, or lentils; 4 tablespoons peanut butter.

VEGETABLE-FRUIT GROUP

Foods Included

All vegetables and fruits. This guide emphasizes those that are valuable as sources of vitamin C and vitamin A.

Sources of Vitamin C

Good sources.—Grapefruit or grapefruit juice; orange or orange juice; cantaloup; guava; mango; papaya; raw strawberries; broccoli; brussels sprouts; green pepper; sweet red pepper.

Fair sources.—Honeydew melon; lemon; tangerine or tangerine juice; watermelon; asparagus tips; raw cabbage; collards; garden cress; kale; kohlrabi; mustard greens; potatoes and sweetpotatoes cooked in the jacket; spinach; tomatoes or tomato juice; turnip greens.

Sources of Vitamin A

Dark-green and deep-yellow vegetables and a few fruits, namely: Apricots, broccoli, cantaloup, carrots, chard, collards, cress, kale, mango, persimmon, pumpkin, spinach, sweetpotatoes, turnip greens and other dark-green leaves, winter squash.

Amounts Recommended

Choose 4 or more servings every day, including:

1 serving of a good source of vitamin C or 2 servings of a fair source.

1 serving, at least every other day, of a good source of vitamin A. If the food chosen for vitamin C is also a good source of vitamin A, the additional serving of a vitamin A food may be omitted.

The remaining 1 to 3 or more servings may be of any vegetable or fruit, including those that are valuable for vitamin C and for vitamin A.

Count as 1 serving: ½ cup of vegetable or fruit; or a portion as ordinarily served, such as 1 medium apple, banana, orange, or potato, half a medium grapefruit or cantaloup, or the juice of 1 lemon.

MILK GROUP

Foods Included

Milk—fluid whole, evaporated, skim, dry, buttermilk.

Cheese—cottage; cream; Cheddar-type, natural or process.

Ice cream.

[Illustration: Dairy products]

Amounts Recommended

Some milk every day for everyone.

Recommended amounts are given below in terms of 8-ounce cups of whole fluid milk:

Children under 9 2 to 3 Children 9 to 12 3 or more Teen-agers 4 or more Adults 2 or more Pregnant women 3 or more Nursing mothers 4 or more

Part or all of the milk may be fluid skim milk, buttermilk, evaporated milk, or dry milk.

Cheese and ice cream may replace part of the milk. The amount of either it will take to replace a given amount of milk is figured on the basis of calcium content. Common portions of cheese and of ice cream and their milk equivalents in calcium are:

1-inch cube Cheddar-type cheese = ½ cup milk ½ cup cottage cheese = ■ cup milk 2 tablespoons cream cheese = 1 tablespoon milk ½ cup ice cream = ¼ cup milk

BREAD-CEREAL GROUP

Foods Included

All breads and cereals that are whole grain, enriched, or restored; _check labels to be sure_.

Specifically, this group includes: Breads; cooked cereals; ready-to-eat cereals; cornmeal; crackers; flour; grits; macaroni and spaghetti; noodles; rice; rolled oats; and quick breads and other baked goods if made with whole-grain or enriched flour. Bulgur and parboiled rice and wheat also may be included in this group.

[Illustration: Bread products]

Amounts Recommended

Choose 4 servings or more daily. Or, if no cereals are chosen, have an extra serving of breads or baked goods, which will make at least 5 servings from this group daily.

Count as 1 serving: 1 slice of bread; 1 ounce ready-to-eat cereal; ½ to ¾ cup cooked cereal, cornmeal, grits, macaroni, noodles, rice, or spaghetti.

OTHER FOODS

To round out meals and meet energy needs, almost everyone will use some foods not specified in the four food groups. Such foods include: unenriched, refined breads, cereals, flours; sugars; butter, margarine, other fats. These often are ingredients in a recipe or added to other foods during preparation or at the table.

Try to include some vegetable oil among the fats used.

Maintaining desirable weight

It is best to maintain desirable weight for one's height at all ages, even during childhood. Here are two principles that you can use—

• Reduce food intake as you become less active. Exercise and activity use up energy—or calories. If you cut down activity but not food, you are providing more energy than the body needs. The excess is stored as fat.

• Reduce food intake as you—as an adult—get older. As adults grow older, less energy is needed to keep the body functioning.

To reduce food intake without shortchanging the body of essential nutrients, follow the pattern of choices suggested by the Daily Food Guide. Weight watchers need the same types of food for health as everyone else. Crash diets and food fads are not the answer and may be dangerous to health.

Cut down on food, but don't cut out any important kinds of foods.

Snacks are counted as a part of the day's total food. Sensible snacking can help meet nutritional needs, but indiscriminate eating between meals usually leads to more calories than are wanted, less of some nutrients than are needed.

Specific information on controlling weight is given in Home and Garden Bulletin 74, "Food and Your Weight." It includes basic weight-control facts, suggestions for reducing or gaining weight, meals and menus, and calorie values of common foods.

Tips on meal planning

Keep these points in mind when you plan meals for your family:

• Include a variety of foods each day and from day to day. Introduce a new food from time to time.

• Vary flavors and textures. Contrast strong flavor with mild, sweet with sour. Combine crisp textures with smooth.

• Try to have some meat, poultry, fish, eggs, milk or cheese at each meal.

• Make a collection of nutritious recipes that the family enjoys and serve them often.

• Brighten food with color—a slice of red tomato, a sprig of dark greens, or other garnish.

• Combine different sizes and shapes of food in a meal, when possible.

Servings and Pounds

If you are a thrifty food shopper, you learn to buy the kinds and amounts of food that your family will use—with a minimum of waste. To avoid waste and to make the most of your food dollar, you also need to know how many servings you get from a market unit, such as 1 pound of fresh carrots or a 10-ounce package of frozen peaches.

Information in this section can help you decide how much to buy to feed your family.

The amount of meat, poultry, and fish to buy varies with the amount of bone, fat, and breading.

Meat, poultry, and fish

Servings per pound[1] =MEAT= Much bone or gristle 1 or 2 Medium amounts of bone 2 or 3 Little or no bone 3 or 4 =POULTRY (READY-TO-COOK)= Chicken 2 or 3 Turkey 2 or 3 Duck and goose 2 =FISH= Whole 1 or 2 Dressed or pan-dressed 2 or 3 Portions or steaks 3 Fillets 3 or 4

[1] Three ounces of cooked lean meat, poultry, or fish per serving.

Vegetables and fruits

For this table, a serving of vegetable is ½ cup cooked vegetable unless otherwise noted. A serving of fruit is ½ cup fruit; 1 medium apple, banana, peach, or pear; or 2 apricots or plums. A serving of cooked fresh or dried fruit is ½ cup fruit and liquid.

Servings per pound[2] =FRESH VEGETABLES= Asparagus 3 or 4 Beans, lima[2] 2 Beans, snap 5 or 6 Beets, diced[3] 3 or 4 Broccoli 3 or 4 Brussels sprouts 4 or 5 Cabbage: Raw, shredded 9 or 10 Cooked 4 or 5 Carrots: Raw, diced or shredded[3] 5 or 6 Cooked[3] 4 Cauliflower 3 Celery: Raw, chopped or diced 5 or 6 Cooked 4 Kale[4] 5 or 6 Okra 4 or 5 Onions, cooked 3 or 4 Parsnips[3] 4 Peas[5] 2 Potatoes 4 Spinach[6] 4 Squash, summer 3 or 4 Squash, winter 2 or 3 Sweetpotatoes 3 or 4 Tomatoes, raw, diced or sliced 4

[2] As purchased.

[3] Bought in pod.

[4] Bought without tops.

[5] Bought untrimmed.

[6] Bought prepackaged.

Servings per package (9 or 10 oz.) =FROZEN VEGETABLES= Asparagus 2 or 3 Beans, lima 3 or 4 Beans, snap 3 or 4 Broccoli 3 Brussels sprouts 3 Cauliflower 3 Corn, whole kernel 3 Kale 2 or 3 Peas 3 Spinach 2 or 3

Servings per can (1 lb.) =CANNED VEGETABLES= Most vegetables 3 or 4 Greens, such as kale or spinach 2 or 3

Servings per pound =DRY VEGETABLES= Dry beans 11 Dry peas, lentils 10 or 11

Servings per market unit[7] =FRESH FRUIT= Apples } Bananas } Peaches } 3 or 4 per pound Pears } Plums }

Apricots } Cherries, sweet } 5 or 6 per pound Grapes, seedless }

Blueberries } Raspberries } 4 or 5 per pint Strawberries 8 or 9 per quart

[7] As purchased.

Servings per package (10 or 12 oz.) =FROZEN FRUIT= Blueberries 3 or 4 Peaches 2 or 3 Raspberries 2 or 3 Strawberries 2 or 3

Servings per can (1 lb.) =CANNED FRUIT= Served with liquid 4 Drained 2 or 3

Servings per package (8 oz.) =DRIED FRUIT= Apples 8 Apricots 6 Mixed fruits 6 Peaches 7 Pears 4 Prunes 4 or 5

Smart Buying

Meat

Your best guides for selecting meat are the U.S. Department of Agriculture grades. Federally graded meats carry a purple grade stamp—a shield enclosing the letters “USDA” and the grade name. These stamps divide the wide range of meat quality into several groups.

Grade stamps appear on most retail beef, veal, calf, lamb, and mutton cuts. Pork is not usually graded. Some meat packers, wholesalers, and retailers use their own brand names to designate the quality levels of their products.

USDA Prime, the top grade, is used largely by hotels and restaurants. USDA Choice and USDA Good are the grades most commonly found in retail markets. USDA Standard and Commercial grades are not often sold at retail.

[Illustration:

38 U. S. INSP'D & P'S'D

U. S. INSPECTED AND PASSED BY DEPARTMENT OF AGRICULTURE EST. 38

USDA meat inspection marks.]

Another purple stamp that may appear on fresh retail meat cuts is the circular mark of Federal meat inspection (below, left). This shows that meat is inspected and passed for wholesomeness, and that it is processed under strict sanitary conditions. A round mark of Federal meat inspection (below, right) also appears on processed meat products to show they are made from wholesome meat, are processed under sanitary conditions, and are truthfully labeled. All fresh or processed meat products that are shipped from one State to another must bear a mark of Federal inspection.

Not all meat is federally inspected. Some States and cities have their own regulations for locally produced meats. However, the Wholesome Meat Act of 1967 will ultimately assure consumers that all meat is inspected by either the Federal Government or an adequate State system.

Meat and your money

At the meat counter, consider the amount of cooked lean meat you will get for the money you pay.

The prices for a pound of beef chuck roast, pork rib roast, ground beef, and beef liver may be about the same at your store. In many instances, a pound of these roasts will provide only about half as much cooked lean meat as a pound of ground beef or beef liver. The other half of the pound of roast is bone, excess fat, and drippings.

So it would take twice as many pounds—and twice as much money—to feed your family the roasts as it would the ground beef or liver, even though the price per pound is the same.

Poultry

In retail markets, ready-to-cook poultry is available chilled or frozen, whole or cut up. Processed poultry products are also on the market in canned, frozen, dehydrated, and other convenient forms.

[Illustration: USDA poultry inspection and grademarks.]

Look for both the round U.S. Department of Agriculture inspection mark and the shield-shaped grademark on the poultry you buy.

The round USDA inspection mark (above, left) means that poultry and poultry products have been officially inspected for wholesomeness, are truthfully labeled, and are not adulterated. USDA inspection is required in plants that produce poultry products for sale across State lines or in foreign trade.

The shield-shaped grademark (above, right) shows that the poultry has been officially graded for quality. Poultry must be USDA-inspected before it can be federally graded. The U.S. grades for poultry are based on meatiness, freedom from defects, and general appearance. The best grade of poultry is marked "USDA Grade A."

Chicken, turkey, duck, and goose are common forms of poultry. Guinea is available in some markets. The label may suggest suitable cooking methods and indicate the age of the poultry—for chicken: "broiler or fryer," "roaster," "stewing chicken;" for turkey: "fryer-roaster," "young hen," "young tom," "mature turkey."

Types of poultry

Broilers, fryers, roasters, capons, and Rock Cornish game hens are young chickens with tender meat. Stewing chickens, hens, and fowl are mature chickens with less tender meat. Turkeys labeled fryer-roaster or young turkey are young birds with tender meat. Most ducks are marketed young as ducklings—broilers, fryers, and roasters. Most geese and guineas are marketed as young geese and young guineas.

Ready-to-cook chickens are sold chilled or frozen—whole or cut into parts. Most ready-to-cook turkeys are marketed frozen whole, in a wide range of sizes; some are available chilled. Frozen turkey halves, quarters, or parts are sometimes available. Ducks, geese, and guineas—like turkeys—are generally marketed frozen whole. Ducklings are also available as cut-up parts.

Frozen poultry, stuffed and ready for the oven, is available in many markets. Boneless poultry roasts and rolls—so convenient—are also on the market.

Fish

Today there are about 240 commercial species of fish and shellfish marketed in the United States. They may be fresh, frozen, or canned.

Fresh fish are generally available by the pound in these forms—whole, dressed, and in steaks, fillets, and chunks. Most fish dealers will clean, dress, or fillet your fish for you. They can also tell you what fish are in season and what fish are a good buy.

Frozen fish are usually packed during the season when they are plentiful and are held in freezer storage until distributed. This means that you can buy most fish throughout the year. Frozen fish come whole, dressed, and in steaks, fillets, chunks, portions, and sticks.

Canned fish and specialty items containing fish are ready to serve or use as bought. Canned tuna, salmon, mackerel, and Maine sardines are widely available.

Market forms

Familiarize yourself with these market forms of fish:

Whole.—Fish marketed just as they come from the water. Ask your dealer to scale, eviscerate, and remove head, tail, and fins.

Dressed or pan-dressed.—Fish with scales and entrails removed, and—usually—head, tail, and fins removed. Small fish are called pan-dressed and are ready to cook as purchased. Large dressed fish may be cooked as purchased, but often are filleted or cut into steaks or chunks.

Steaks.—Cross-section slices from large dressed fish cut ■ to 1 inch thick. Steaks can be cooked as purchased.

Fillets.—Sides of the fish cut lengthwise away from the backbone. They may be skinned or the skin may be left on. Fillets are ready to cook as purchased.

Chunks.—Cross sections of large dressed fish. A cross section of the backbone is the only bone in a chunk. They are ready to cook as purchased.

Raw breaded fish portions.—Portions cut from frozen fish blocks, coated with a batter, breaded, packaged, and frozen. Raw breaded fish portions weigh more than 1½ ounces. They are ready to cook as purchased.

Fried fish portions.—Portions cut from frozen fish blocks, coated with a batter, breaded, partially cooked, packaged, and frozen. Fried fish portions weigh more than 1½ ounces. They are ready to heat and serve as purchased.

Fried fish sticks.—Sticks cut from frozen fish blocks, coated with a batter, breaded, partially cooked, packaged, and frozen. Fried fish sticks weigh up to 1½ ounces. They are ready to heat and serve as purchased.

Inspection and grading

The U.S. Department of the Interior provides an official inspection service that enables you to identify high-quality seafoods. Such products may be identified by the official USDI grade or inspection shields that appear on the label. Fishery products that display these shields have been processed under continuous in-plant inspection and have met definite quality, processing, and packaging requirements.

Eggs

Buy graded eggs in cartons at a store that keeps them in refrigerated cases. Federally graded eggs are identified with a shield-shaped grademark that indicates the quality at the time of grading. If they have been properly handled since grading, there

should be little loss in quality.

Quality.—U.S. Grade AA (or Fresh Fancy) and Grade A eggs are excellent for all purposes, but are especially good for poaching and frying where the appearance of the finished product is important. Grade B eggs are satisfactory for use in cooked dishes.

The grade of the egg does not affect its food value; lower grades are as high in nutrients as top grades. Buy either white or brown eggs. The color of the shell does not affect the nutritive value or quality of the egg.

Size.—Eggs are also classified by size according to weight per dozen. Size is independent of quality; large eggs may be of high or low quality and high-quality eggs may be of any size. Common market sizes of eggs and the minimum weight per dozen:

U.S. Extra Large—27 ounces. U.S. Large—24 ounces. U.S. Medium—21 ounces. U.S. Small—18 ounces.

The substitution of one size egg for another often makes little difference in recipe results. However, in some recipes—for example in sponge and angelfood cakes—the proportion of egg to other ingredients is very important. For these recipes, it may be necessary to increase the number of eggs if you are using a smaller size.

Fresh fruits and vegetables

Fresh fruits and vegetables are usually best in quality and lowest in cost when in season.

Whatever fruit or vegetable you are buying, look first for freshness. Pointers on selecting some fruits and vegetables follow on page 12.

Fruits

Apples.—Good color usually indicates full flavor.

Bananas.—Bananas should be firm, fresh in appearance, and unscarred. Yellow or brown-flecked ones are ready for immediate use. Select slightly green-colored bananas for use within a few days.

Berries.—Select plump, solid berries with good color. Avoid wet or leaky berries. Blackberries and raspberries with clinging caps may be underripe. Strawberries without caps may be too ripe.

Grapes.—Grapes should be plump, fresh in appearance, and firmly attached to the stems. Red or black varieties should be well colored for the variety. Most white or green varieties should have a slightly amber tone.

Melons (except watermelons).—Ripe cantaloups have a yellowish surface color; honeydews, a creamy color; crenshaws, a golden-yellow color mottled with green; casabas, a yellow color; and persian melons, a dull gray-green color. Ripe melons of these types usually have a fruity aroma and a slight softening at the blossom end. A ripe cantaloup has no stem; other melons may have stems attached.

Oranges, grapefruit, and lemons.—Choose those heavy for their size. Smooth, thin skins usually indicate more juice. Most skin markings do not affect quality. Oranges with a slight greenish tinge may be just as ripe as fully colored ones. Light or greenish-yellow lemons are more tart than deep-yellow ones.

Peaches.—Best quality peaches are fairly firm, not bruised, with yellow or red color over the entire surface.

Pears.—Some pears, especially winter varieties, are marketed when slightly underripe and need to be ripened at home—at room temperature. Pears are ripe and ready to eat when they yield slightly to moderate pressure.

Pineapples.—Pineapple varieties vary greatly in color. Ripe pineapples have a fragrant, fruity aroma. Usually, the heavier the fruit for its size, the better the quality. Avoid pineapples that have decayed or moldy spots.

Watermelons.—Ripe watermelons have a somewhat dull surface and a creamy color underneath. The interior should be fully red and firm, and should have few immature seeds.

Vegetables

Asparagus.—Stalks should be tender and firm; tips should be close and compact. Choose the stalks with little white—they are more tender. Use asparagus promptly—it toughens rapidly.

Beans, snap.—Choose slender beans with no large bumps (bumps indicate large seeds). Avoid beans with dry-looking pods.

Broccoli.—Look for small flower buds on compactly arranged heads with good green color. Avoid yellowing, soft, or spreading heads.

Brussels sprouts.—The heads should be firm with good green color. Yellowing outer leaves and softness indicate aging. Smudgy, dirty spots may indicate insect damage or decay.

Cabbage.—Choose heads that are firm and heavy. Outer leaves should be fresh, green, and free from worm-holes.

Cauliflower.—Choose heads that are compact, firm, and white or creamy white. Avoid discolored heads and those with soft spots.

Celery.—Best-quality celery is fresh and crisp. It is clean and has leaves that appear fresh; stems do not have black or brown discoloration. Avoid pithy, woody, or very stringy celery.

Corn.—Good-quality fresh corn has husks that are fresh and green. The ears are well filled with plump, firm, milky kernels. Immature ears of corn have small, undeveloped, watery kernels. Overmature ears have very firm, large, starchy kernels, often indented.

Cucumbers.—Choose firm, slender cucumbers for best quality. Avoid yellowed cucumbers and those with withered or shrivelled ends.

Lettuce (head).—Select heads that are green, fresh, crisp, and fairly firm to firm. Head lettuce should be free from rusty appearance and excessive outer leaves.

Onions (dry).—Size and color do not affect flavor or quality of dry onions. Clean, hard, well-shaped onions with dry skins are usually of good quality. Moisture at the neck may be a sign of decay. Mild-flavored onions, which are often large, may be elongated or flat. Stronger-flavored onions are usually medium size and globe shaped.

Peas and lima beans.—Select pods that are well filled but not bulging. Avoid dried, spotted, yellowed, or flabby pods.

Potatoes.—Best-quality potatoes are firm, smooth, and well shaped. They are free from cuts, blemishes, and decay. To judge quality more easily, look for potatoes that are reasonably clean. Avoid potatoes with wasteful deep eyes. Potatoes with green skins may be bitter. If you plan to buy a large quantity of potatoes, buy a few first to see if they are the kind you want. Early-crop potatoes, harvested in spring and summer, tend to be less mealy when cooked than those harvested later.

Root vegetables.—Choose smooth, firm vegetables. Very large carrots may have woody cores; oversized radishes may be pithy; oversized turnips, beets, and parsnips may be woody. The size and condition of the tops on root vegetables do not necessarily indicate the eating quality.

Sweetpotatoes.—Choose sweetpotatoes that are clean, smooth, well shaped, and firm. Damp or soft spots may indicate decay. There are two types of sweetpotatoes. The moist type has soft, moist, orange-colored flesh and bronze or rosy skin. The dry type has firm, dry, somewhat mealy, yellow-colored flesh and yellow or light-brown skin.

Tomatoes.—Choose tomatoes that are plump, firm, and uniformly pink, red, or yellow in color. They should be free from growth cracks, scars, and bruises. The best flavored tomatoes are ripened on the vine.

For more information, see Home and Garden Bulletins 141, “How to Buy Fresh Fruits,” and 143, “How to Buy Fresh Vegetables.”

Canned and frozen foods

Canned.—You may want to choose the highest quality for salads, or for serving “as is.” But second quality may do for combination dishes such as stews, casserole dishes, soups, and fruit puddings, where uniform size, shape, or color is not important.

Frozen.—Buy only packages that are frozen solid. Avoid partially thawed packages that feel soft or are stained. Thawing and refreezing lower quality.

Wise Storing

Meat, poultry, and fish

All meat should be promptly refrigerated.

The transparent wrap on prepackaged meat, poultry, or fish is designed for refrigerator storage at home for 1 or 2 days.

Meat or poultry wrapped in meat paper when brought from the store—or prepackaged roasts and steaks that may be stored in the refrigerator for 3 to 5 days—should be unwrapped, placed on a platter or tray, and loosely covered before refrigerating. Wrap and store fish separately from other foods. Poultry giblets should also be wrapped and stored separately.

Keep cooked meat, poultry, and fish, and the gravy or broth made from them, in covered containers in the refrigerator. Use within 1 or 2 days.

Cured and smoked meats.—ham, frankfurters, bacon, sausage—can be stored in their original containers in the refrigerator. Mild-cured hams are similar to fresh meats in keeping quality. Use whole hams within a week, half hams and slices within 3 to 5 days. For best flavor, use bacon, franks, and smoked sausages within a week.

Eggs

To help maintain quality, store eggs in the refrigerator promptly after purchase—large end up.

For best flavor and cooking quality, use eggs within 1 week if possible. Eggs held in the refrigerator for a long time may develop off-flavors and lose some thickening and leavening power.

Cover leftover yolks with cold water and refrigerate in a tightly covered container. Refrigerate leftover egg whites, too, in a tightly covered container. Use leftover yolks or whites within 1 or 2 days.

Fresh fruits and vegetables

Fresh fruits should be ripe when stored in the refrigerator. Some unripe fruits will ripen if left for a time at room temperature—preferably in a cool room between 60° and 70° F.

Keep bananas at room temperature. They will turn dull brown if refrigerated. Sort berries and cherries; then refrigerate, unwashed. Use promptly. Refrigerate ripe pineapples.

Sweet corn keeps best if refrigerated uncovered in husks; use it promptly. Removing tops from carrots, beets, and radishes reduces wilting. Storing potatoes in a cool, dark place prevents greening.

STORAGE GUIDE FOR FRUITS AND VEGETABLES.

Hold at room temperature until ripe; then refrigerate, uncovered:

Apples Apricots Avocados Berries Cherries Grapes Melons, except watermelons Nectarines Peaches Pears Plums Tomatoes

Store in cool room or refrigerate, uncovered:

Grapefruit Lemons Limes Oranges

Store in cool room, away from bright light:

Onions, mature Potatoes Rutabagas Squash, winter Sweetpotatoes

Refrigerate, covered:

Asparagus Beans, snap or wax Beets Broccoli Cabbage Carrots Cauliflower Celery Corn, husked Cucumbers Greens Onions, green Parsnips Peas, shelled Peppers, green Radishes Squash, summer Turnips

Refrigerate, uncovered:

Beans, lima, in pods Corn, in husks Peas, in pods Pineapples Watermelons

Fats and oils

Refrigerate lard, butter, margarine, drippings, and opened containers of cooking and salad oils. You can store most firm vegetable shortenings (those that have been hydrogenated), covered, at room temperature. Refrigerate opened jars of salad dressing; do not freeze.

Canned, frozen, and dried foods

Canned foods.—Store in a dry place at room temperature (not above 70° F.).

Frozen foods.—Can be stored in freezing unit of refrigerator up to 1 week. For longer storage, keep in a freezer at 0° F.

Dried foods.—Store _dried fruits_ in tightly closed containers at room temperature (not above 70° F.). In warm, humid weather, refrigerate.

Store _nonfat dry milk_ in a closed container at a temperature of 75° F., or lower. Because of its higher milkfat content, _dry whole milk_ does not keep as well as nonfat dry milk. Keep dry whole milk in a tightly closed container in the refrigerator. Refrigerate _reconstituted dry milk_ as you would fresh fluid milk.

Ingredients and Measurements

About ingredients

Ingredients that may be used in place of other ingredients are listed on the next page.

Recipes in this bulletin were tested with the ingredients listed. Sometimes a choice of ingredients is given in the recipe or under Variations of the recipe.

“Flour” refers to _all-purpose flour, unsifted_. In a few recipes, where “cake flour” is specified it is also unsifted. Recipes in this bulletin are not intended for use with either instantized or self-rising flour.

“Baking powder” refers to _double-acting baking powder_ that leavens during mixing and again during baking. Quick-acting baking powder (containing cream of tartar) is single-acting; it can be used most satisfactorily in foods that are mixed and baked immediately. (See One Ingredient For Another, p. 17, for amounts.)

“Fat or oil” refers to any type—butter, margarine, shortening, lard, or any kind of vegetable oil. In recipes specifying a particular type of fat—“butter or margarine,” for example—you’ll have best results with the fat suggested. Recipes in this bulletin are not intended for use with whipped fats.

Measuring foods

All measurements given in this bulletin are level.

Frequently used food measurements are given below.

1 tablespoon = 3 teaspoons 1 fluid ounce = 2 tablespoons ¼ cup = 4 tablespoons ■ cup = 5■ tablespoons ½ cup = 8 tablespoons ■ cup = 10■ tablespoons ¾ cup = 12 tablespoons 1 cup = 16 tablespoons or 8 fluid ounces 1 pint = 2 cups 1 quart = 2 pints or 4 cups

Part of cup.—Use tablespoons or small measures-½, ■, ¼ cup—for greater accuracy.

Brown sugar.—Pack firmly into cup or spoon and level off top with straight, thin edge of spatula or knife.

Solid fats.—Pack fat firmly into cup or smaller measure and level off top with straight, thin edge of spatula or knife.

To measure less than 1 cup, you can also use the water method: Partly fill a cup with cold water, leaving enough space for the amount of fat needed. (To measure ¼ cup of fat, for example, fill cup with water to ¾ mark.) Spoon fat into cup, push under water until water level reaches 1-cup mark. Drain thoroughly before using fat.

For solid fat in sticks or pounds, cut off amount needed. A 1-pound form measures about 2 cups; a ¼-pound stick of butter or margarine measures ½ cup.

Flour.—Spoon flour lightly into measuring cup until measure is overflowing. Do not shake or tap cup. Level off top with straight, thin edge of spatula or knife.

Fine meal, fine crumbs.—Stir lightly with fork or spoon. Measure like flour.

Baking powder, cornstarch, cream of tartar, spices.—Dip spoon into container and bring it up heaping full. Level off top with straight, thin edge of spatula or knife.

Dry milk.—Pour dry milk from spout or opening in package, or spoon lightly, into measuring cup until measure is overflowing. Do not shake. Level off top with straight, thin edge of spatula or knife.

ONE INGREDIENT FOR ANOTHER

=For these= =You may use these=

1 whole egg, for baking or thickening • 2 egg yolks.

1 cup butter or • ■ cup vegetable or animal shortening margarine for plus ½ teaspoon salt. baking

1 ounce unsweetened chocolate • 3 tablespoons cocoa plus 1 tablespoon fat.

1 teaspoon double-acting {• 2 teaspoons quick-acting baking powder. baking {• ¼ teaspoon baking soda plus ½ cup sour powder { milk or buttermilk instead of ½ cup { sweet milk.

1 cup buttermilk or {• 1 cup fluid whole milk plus 1 sour milk, for { tablespoon vinegar or lemon juice. baking {• 1 cup fluid whole milk plus 1¾ { teaspoons cream of tartar.

1 cup fluid whole milk {• ½ cup evaporated milk plus ½ cup water. {• 1 cup reconstituted nonfat dry milk {• plus 2½ teaspoons butter or margarine.

1 cup fluid skim milk • 1 cup reconstituted nonfat dry milk.

1 tablespoon flour, {• ½ tablespoon cornstarch. for thickening {• 2 teaspoons quick-cooking tapioca.

1 cup cake flour, for baking • ■ cup all-purpose flour.

NOTE: Seven-eighths cup equals 1 level cup minus 2 tablespoons.

Main Dishes

Foods that abound in protein—meat, poultry, fish, eggs, and cheese—make satisfying main dishes. Thrifty main dishes often combine these protein-rich foods with vegetables and cereals—beef stew with vegetables or dumplings, chicken with rice, fish with stuffing, cheese with macaroni.

Dry beans and peas are also economical choices for main dishes.

If the main dish is not high in protein, you can supply additional protein with other foods in the meal. If, for example, a pound of meat is to serve eight persons, you might combine it with vegetables or cereal in a casserole or stew, have milk to drink, and serve cheese-topped apple pie for dessert.

Meat

Meat cooked at low to moderate temperatures is more tender, juicy, and flavorful than meat cooked at high temperatures. There is more meat to serve because there is less shrinkage at low temperatures.

Beef may be cooked rare, medium, or well done. Lamb is enjoyed either medium or well done, but veal and pork are usually cooked well done.

Broiling, pan-frying, and roasting are recommended for tender meats only. Less tender cuts are more satisfactory if braised, pot-roasted, or simmered. For suggested methods for cooking, see guide on [page 19].

Frozen meat need not be thawed before cooking, but extra cooking time will be required if it is not thawed first.

Roasting ... beef, veal, lamb, pork

Place roast, fat side up, on a rack in a shallow pan. Do not add water; do not cover. Season either before or after cooking.

Check the timetable (p. 20) for approximate roasting times. The quality of the meat, its size and shape, and its temperature at the start of cooking will affect the roasting time. Times given here are for meats at refrigerator temperature. Frozen roasts may take 1½ to 2 times as long to cook as unfrozen roasts of the same weight and shape.

If you are using a meat thermometer, insert it so the tip is at the center of the thickest part of the roast, and not touching bone or fat.

Broiling ... beef, lamb, cured ham

Slash fat around edge of meat to prevent curling. Place meat on cold broiler grid.

Broiling temperature can be regulated by the distance meat is placed from heat source and whether the door is open or closed during broiling. Because broilers vary widely, follow the manufacturer’s directions. If you like meat well done, place it farther from the heat source than for medium or rare meat—to avoid burning the outside before the center is cooked. Place thicker cuts farther from the heat source than thin ones, for the same reason.

[8] Can also be served without heating, if desired.

Broil until top side of meat is browned, about half of total cooking time. Season, turn, and brown other side. Use timetable (next page) as a guide to total broiling time. To tell if meat is done, cut into it along bone and observe color.

Use a low temperature for broiling frozen meat, so the surface does not char before the interior thaws and cooks. Allow 1½ to 2 times as long as specified in the timetable on page 21.

Pan broiling ... beef, lamb, pork

Choose thin steaks, chops, or ham slices (1 inch thick or less). Or shape meat patties less than an inch thick.

Slash fat around edge of meat to prevent it from curling. Grease pan lightly with fat or rub pan with fat edge of meat.

Cook meat slowly over moderate heat, turning occasionally as necessary. Pour off excess fat as it accumulates. Total cooking time will be 10 to 20 minutes, depending on the degree of doneness desired. Pork chops may take a little longer.

Remove meat from pan, season, and serve.

Braising ... beef, veal, lamb, pork

Brown meat slowly on all sides in enough added fat to keep meat from sticking. Use a heavy pan. Meats may be floured or not, as desired, before browning. Floured meats brown better than unfloured meats. Meats that have a considerable amount of fat and that are not floured can be browned without added fat.

Season the meat. If necessary to prevent overbrowning, add a small amount of liquid (about ½ cup for a roast). Many cuts of meat can be braised without added liquid. Steam from meat juices trapped in a covered pan provides enough moisture. Cover pan tightly.

Cook slowly over low heat or in a 350° F. oven until tender, adding more liquid if needed. Use the timetable (p. 22) as a guide to braising time.

Quick beef pie

6 servings

1½ pounds ground beef 1 medium-size onion, chopped ½ teaspoon salt 1 can (10½ ounces) condensed tomato soup 1 can (1 pound) cut green beans, drained ¼ teaspoon pepper 1½ cups seasoned mashed potatoes ½ cup shredded Cheddar cheese

Crumble beef into large frypan. Add onion and salt, and cook until browned. Drain off excess fat.

Add soup, green beans, and pepper; simmer 5 minutes. Pour into greased 2-quart casserole.

Drop potatoes in mounds onto hot meat mixture. Sprinkle with cheese. Bake at 350° F. (moderate oven) 20 minutes.

Menu suggestion

Serve with buttered carrots, stuffed prune salad, and brownies.

Beef stroganoff

6 servings

■ cup flour 1 teaspoon salt ¼ teaspoon pepper 1 pound sirloin tip steak, cut in very thin strips ½ cup finely chopped onion ¼ cup fat or oil 1 can (10½ ounces) condensed cream of mushroom soup 1 can (8 ounces) sliced mushrooms, drained 1 cup sour cream Cooked rice Paprika Parsley

Combine flour, salt, and pepper. Coat meat strips with flour mixture. Brown meat in hot fat in a large frypan. Add onion and cook until clear. Drain off excess fat.

Add soup and mushrooms. Simmer, covered, 10 to 15 minutes. Blend in sour cream and remove from heat. Serve over rice. Sprinkle with paprika and garnish with parsley.

Menu suggestion

Serve with green beans, cucumber and tomato salad, and have sliced peaches and poundcake for dessert.

Luncheon special

6 servings

2 cups medium white sauce (p. 57) 2 cups shredded Cheddar cheese 1 package (10 ounces) frozen cut green beans, cooked and drained 1 can (12 ounces) luncheon meat, cut in thin strips 1 tablespoon chopped pimiento White pepper, as desired Toast triangles

To hot white sauce, add remaining ingredients except toast. Cook over low heat 10 minutes, or just until cheese melts and mixture is hot. Serve on toast triangles.

Menu suggestion

Serve with glazed carrots, fruit salad, and chocolate pudding.

Curried meat

6 servings

2 beef bouillon cubes 1■ cups hot water 1½ cups sliced celery 2 tablespoons chopped onion 3 tablespoons fat or oil 1 tablespoon cornstarch 1 teaspoon curry powder ½ teaspoon salt 3 cups chopped, cooked lamb, pork, or veal

Dissolve bouillon cubes in hot water.

Lightly brown celery and onion in hot fat in a large frypan. Blend in cornstarch and seasonings. Slowly stir in bouillon. Add meat. Cook mixture over moderate heat 15 to 20 minutes, stirring as needed to prevent sticking. Serve on rice.

Menu suggestion

Serve with italian green beans, citrus fruit salad, and spiced prune cake.

Sausage and potatoes au gratin

6 servings

1 can (10½ ounces) condensed cream of mushroom soup ½ cup milk ½ cup finely chopped onion ¼ cup chopped green pepper 1 tablespoon chopped pimiento ½ teaspoon salt ¼ teaspoon pepper 4 cups thinly sliced potatoes 1 package (8 ounces) precooked small smoked sausages, cut in bite-size pieces 1 tablespoon butter or margarine ½ cup shredded Cheddar cheese

Combine soup, milk, onion, green pepper, pimiento, salt, and pepper; blend well.

Place half the potatoes in a greased 2-quart casserole. Add half the sausage. Cover with half the soup mixture. Repeat layers. Dot with fat. Cover and bake at 350° F. (moderate oven) about 1¼ hours.

Remove cover. Sprinkle with cheese and bake, uncovered, 15 minutes more, or until potatoes are tender.

Menu suggestion

Serve with brussels sprouts, fruit, and gingerbread.

Ham patties

6 servings

2 cups ground cooked ham 1 cup mashed potatoes 1 tablespoon chopped onion ¼ teaspoon dry mustard ¼ teaspoon salt 1 tablespoon milk 1 egg, beaten ½ cup fine dry breadcrumbs 3 tablespoons fat or oil

Combine ground ham, mashed potatoes, onion, mustard, and ¼ teaspoon salt. Chill about 1 hour. Shape into 12 patties.

Blend milk into beaten egg. Dip patties in egg mixture and then in crumbs.

Fry patties in hot fat until golden brown. Serve with egg sauce (p. 57).

Menu suggestion

Serve with asparagus, molded fruit salad, cheese biscuits, and peanut butter cookies.

Braised liver and onions

6 servings

1½ pounds sliced beef liver ½ cup flour 2 tablespoons fat or oil 1½ teaspoons salt ¼ teaspoon pepper 1 large onion, sliced ¼ cup water

Remove skin and large veins from liver. Coat meat with flour. Heat fat in large frypan over moderate heat and brown liver on one side.

Turn liver, sprinkle with seasonings and cover with onions. Add water and cover pan tightly. Cook over low heat 20 to 30 minutes, or until liver is tender.

Menu suggestion

Serve with stewed okra and tomatoes, spinach salad, and apple crisp.

Spaghetti with meat sauce

6 servings

1 pound ground beef 1 medium-size onion, finely chopped 1 clove garlic, peeled ½ teaspoon oregano 1 teaspoon salt ¼ teaspoon pepper 1 can (6 ounces) tomato paste ¾ cup water 1 can (15 ounces) spanish-style tomato sauce 1 bay leaf 1 tablespoon sugar 4 cups cooked spaghetti ½ cup grated Parmesan or Romano cheese

Crumble ground beef into 4-quart saucepan. Add onion, garlic, oregano, salt, and pepper. Heat to brown meat.

Add tomato paste, water, tomato sauce, and bay leaf. Bring to a boil. Then simmer, uncovered, over low heat 45 minutes. Remove garlic. Add sugar and simmer 15 minutes longer.

Place hot spaghetti on a platter. Cover with meat sauce. Sprinkle with cheese.

Menu suggestion

Serve with tossed green salad and upside-down cake.

Meat loaf

6 servings

1½ pounds ground beef 3 slices soft white bread, torn into very small pieces 1 cup tomato juice or milk ½ cup finely chopped onion 1 egg, beaten 1 teaspoon salt ¼ teaspoon pepper

Mix ingredients thoroughly. Press into a 9- by 5- by 3-inch loafpan or shape into loaf.

Bake uncovered at 350° F. (moderate oven) about 1½ hours. Remove from oven and drain off excess fat.

Menu suggestion

Serve with green bean-mushroom casserole, baked potatoes, celery sticks and olives, and orange sherbet.

Stuffed green peppers

6 servings

3 large green peppers 2 teaspoons salt Boiling water 1 pound ground beef 1½ cups cooked rice 2 tablespoons finely chopped celery 2 tablespoons finely chopped onion ¼ cup chili sauce 2 teaspoons salt ¼ teaspoon pepper 1 egg 2 tablespoons shredded Cheddar cheese

Halve peppers lengthwise; remove stems, seeds, and membranes. Add 2 teaspoons salt to enough boiling water to cover peppers; boil peppers 5 minutes. Drain.

Combine other ingredients except cheese; mix well. Fill pepper halves with this mixture and place in ½ inch of hot water in a baking pan.

Bake uncovered at 350° F. (moderate oven) 45 to 55 minutes. Sprinkle cheese over peppers and bake 5 minutes longer, or just until cheese melts.

Menu suggestion

Serve with corn pudding and coleslaw, and have your favorite ice cream for dessert.

Saucy luncheon meat

6 servings

2 packages (3 ounces each) cream cheese 2 tablespoons milk 1 pound bologna or other luncheon meat, finely diced ¼ cup finely chopped onion 2 tablespoons sliced ripe olives 2 teaspoons prepared mustard ¾ cup canned condensed cream of mushroom soup Biscuits, cooked rice, or noodles

Blend cream cheese with milk in top of double boiler. Add meat, onion, olives, mustard, and soup; mix thoroughly. Heat over simmering water 15 to 20 minutes, stirring occasionally. Serve over biscuits, rice, or noodles.

Menu suggestion

Serve with kale, carrot and pineapple salad, and chocolate chip cookies.

Beef stew

6 servings

■ cup flour 1½ teaspoons salt ■ teaspoon pepper 1½ pounds boneless stew beef, cut in 1-inch cubes 2 tablespoons fat or oil 3 cups water 3 medium-size onions, sliced 4 medium-size potatoes, cut in 1-inch cubes 5 medium-size carrots, quartered 1½ cups frozen peas ¼ cup water

Combine flour, salt, and pepper; coat meat with seasoned flour. Save remaining flour. Brown meat in hot fat in a 4-quart saucepan.

Add water and cover tightly. Simmer until meat is tender, about 1½ hours.

Add onions, potatoes, and carrots. Cover and simmer 15 minutes.

Add peas. Cover and simmer until all vegetables are tender.

Blend ¼ cup water with remaining flour. Add to stew, stirring gently; cook until thickened.

Variation

Irish stew.—Use lean lamb instead of beef. Add 1 turnip, diced, with potatoes and carrots.

Menu suggestion

Serve with tossed green salad and hot biscuits. Have fruit sherbet and cookies for dessert.

Poultry

Serve poultry often—it’s versatile, flavorful, and economical. You can buy chicken and turkey in convenient sizes—chilled or frozen—any day of the year. And for variety, try duck and goose.

Preparing poultry

Ready-to-cook poultry needs little preparation before cooking. Inspect for pinfeathers. Wash and drain poultry.

Keep _frozen poultry_ frozen until time to thaw or cook. Frozen poultry usually is thawed before cooking, but poultry parts or whole poultry frozen without giblets can be cooked without thawing. Cooking time will be longer than for unfrozen poultry. Do not thaw commercially frozen stuffed poultry before cooking.

To thaw poultry in the refrigerator, place frozen poultry on a tray or shallow pan to catch the thawing drip; if unwrapped, cover lightly. Remove giblets from cavity when bird is pliable.

If it is not practical to thaw poultry in the refrigerator, immerse poultry in a watertight wrapper in cold water. Change water often to hasten thawing. Or you can partially thaw poultry in the refrigerator and partially in cold water. It takes 1 to 8 hours to thaw poultry in cold water, or 1 to 3 days in a refrigerator.

Cook poultry promptly after thawing. Stuff poultry just before roasting.

Cooking guides

Most poultry sold whole can be roasted. Stewing chickens and mature turkeys, however, are more tender if braised or stewed. They are good for stews, or to provide cooked meat for casseroles, sandwiches, and salads.

Broiler or fryer chickens can be roasted, ovenbaked, barbecued, or cooked on a rotisserie as well as broiled or fried. Fryer-roaster turkeys weighing 4 or 5 pounds can be roasted whole, or can be cut into parts and fried or broiled.

Rock Cornish game hens can be cooked like broiler or fryer chickens. Small ducks are suitable for broiling or frying; larger ones, for roasting or rotisserie cooking. Geese roast very well.

Roast poultry uncovered for best color and to reduce splitting and shrinkage. Poultry can be roasted with or without stuffing; unstuffed birds take slightly less time to cook. Cook poultry until tender and juicy; do not overcook.

Roasting

Prepare the poultry as directed above. Stuff the body and neck cavities lightly; allow about ½ cup of stuffing per pound of ready-to-cook poultry. See stuffing recipe (p. 28). Or if desired, leave poultry unstuffed.

Fold loose neck skin toward back; fasten with a skewer. Turn wingtips back of heavy wingbone to rest against neck skin. Tuck ends of legs under band of skin at tail or fasten legs together close to body.

To roast poultry, place breast side up on a rack in a shallow pan. Do not cover pan and do not add water.

See roasting guide (p. 28) for approximate times for roasting poultry.

A meat thermometer is the best guide to doneness of turkeys. Insert the thermometer into the center of the inner thigh muscle. Make sure it does not touch the bone.

Salt the giblets and neck, seal them in aluminum foil, and roast along with the poultry. Or simmer them in salted water until tender.

You can baste poultry with pan drippings or a little fat if you like.

If poultry browns early in the roasting period, cover the breast and drumsticks lightly with aluminum foil or with a thin cloth moistened with fat. After poultry is partly roasted, cut band of skin that holds legs together.

Use any one or more of the following ways to tell if poultry is done:

• A meat thermometer inserted in the center of the inner thigh muscle of a turkey reaches 180° to 185° F. If turkey is stuffed, also check stuffing temperature by inserting a thermometer into the body cavity for 5 minutes. Temperature should reach 165° F.

• Drumstick feels soft when you press meaty part with protected fingers.

• Drumstick moves up and down easily and leg joint gives readily.

CAUTION: Do not partly roast poultry on one day and complete roasting the following day.

ROASTING GUIDE

———————————————————+———————————+———————————+———————————— | | Approximate | Internal |Ready-to-cook | roasting time| temperature Kind of poultry | weight[10] |at 325° F. for| of poultry | | stuffed | when done | | poultry[11] | ———————————————————+———————————+———————————+———————————— | _Pounds_ | _Hours_ | °F. | | | Chickens |1½ to 2½ |1 to 2 | (Broilers, fryers,| | | or roasters) |2½ to 4½ |2 to 3½ | | | | Ducks |4 to 6 |2 to 3 | | | | Geese |6 to 8 |3 to 3½ | |8 to 12 |3½ to 4½ | | | | Turkeys |6 to 8 |3 to 3½ | } 180 to 185 |8 to 12 |3½ to 4½ | } in center |12 to 16 |4½ to 5½ | } of inner |16 to 20 |5½ to 6½ | } thigh |20 to 24 |6½ to 7 | } muscle. ———————————————————+———————————+———————————+————————————

[10] Weight of giblets and neck included.

[11] Unstuffed poultry may take slightly less time than stuffed poultry. Cooking time is based on chilled poultry or poultry that has just been thawed—temperature not above 40° F. Frozen unstuffed poultry will take longer. Do not use this roasting guide for frozen commercially stuffed poultry; follow package directions.

Stuffing

About 1 quart

3 tablespoons butter, margarine, or poultry fat ¾ cup chopped celery 3 tablespoons chopped parsley 2 tablespoons chopped onion 1 quart soft breadcrumbs ½ teaspoon savory seasoning ½ teaspoon salt Pepper, as desired

Melt fat in heavy pan; add celery, parsley, and onion, and cook a few minutes.

Combine all ingredients. Mix lightly but well.

Use to stuff poultry, or bake in a separate pan during the last hour of cooking.

NOTE: Allow about ½ cup stuffing per pound of ready-to-cook poultry. This stuffing may be used for baked fish, if desired.

Variation

Nut stuffing.—Omit parsley and savory seasoning and add ½ cup of chopped nutmeats—roasted almonds, pecans, filberts, or cooked chestnuts.

Braised boneless turkey roast

Place boneless turkey roast on a rack in a pan; insert a meat thermometer in the center of the roast; cover pan tightly. Braise in an oven at 400° F. (hot) until thermometer registers about 170° F. Or, follow cooking directions on package.

NOTE: A 3-pound boneless turkey roast requires about 1½ hours cooking time. If desired, uncover roast last 20 minutes to brown.

Broiled chicken

Plump young chicken, about 1½ to 2¼ pounds ready to cook Melted fat or oil Salt and pepper, as desired

Prepare chicken for cooking according to directions on page 26.

Split chicken down the back and, if desired, cut into halves through the breastbone. Break joints and cut off wingtips.

Brush chicken on both sides with melted fat and sprinkle with salt and pepper.

Preheat the broiler and grease broiler rack lightly. Place chicken on the rack, skin side down. Place broiler pan at the distance from heat recommended by the range manufacturer.

Broil chicken 20 to 30 minutes on one side or until browned; turn, brush with fat or oil, and broil until done, 15 to 25 minutes longer.

Menu suggestion

Serve with broccoli, creamed potatoes, and lemon chiffon pie.

Stewed chicken

Use a plump stewing chicken, 3 to 4 pounds ready to cook. Or, you can stew a broiler-fryer chicken, although the flavor will be somewhat milder.

Prepare chicken for cooking according to the directions on page 26. Leave whole or cut in serving-size pieces.

Place the chicken in a deep pan. Add enough water to half cover a whole chicken or to cover pieces. Season as desired.

Cover pan and cook over low heat until the chicken is tender—2 to 3 hours for a stewing chicken, 45 minutes to 1 hour for a broiler-fryer.

Cook giblets with the chicken or separately.

Serve stewed chicken in gravy made by thickening the broth, or use in any recipe that calls for cooked chicken.

Fried chicken

Plump young chicken, 1½ to 3 pounds ready to cook Salt, pepper, flour Fat or oil

Prepare chicken for cooking according to the directions on page 26. Cut in serving pieces.

Season chicken with salt and pepper and roll in flour.

In a heavy frypan, heat ¼ to ¾ cup fat or oil—just enough to cover bottom of pan. Use moderate heat.

Brown chicken pieces on one side; turn and brown on other side.

Continue to cook slowly, uncovered, until tender. Or, if more convenient, cook in oven at 350° F. (moderate) until tender. Cooking time will be from 30 to 45 minutes.

Variation

Oven-fried chicken.—Prepare the chicken according to directions on page 26. Cut in serving pieces. Preheat oven to 400° F. (hot). Shake or roll chicken pieces in seasoned flour and place in a baking pan containing hot fat (■ inch deep or less). Turn pieces to coat both sides with fat. Cook chicken skin side down for 30 minutes; turn; and cook 20 to 30 minutes longer, or until tender.

Menu suggestion

Serve with mashed potatoes, carrots, and green salad. For dessert have cherry pie.

Chicken a la king

6 servings

1 cup frozen green peas 2 tablespoons finely chopped onion ¼ cup chopped green pepper ■ cup boiling water ■ cup flour 1 cup cold milk 2 cups chicken broth 2 teaspoons salt Pepper, as desired ½ teaspoon poultry seasoning 2 cups diced cooked chicken or turkey 1 can (4 ounces) mushroom stems and pieces, drained and chopped 1 tablespoon chopped pimiento Cooked rice, toast, or biscuits

Cook peas, onion, and green pepper in boiling water in a covered pan 5 minutes. Drain; save the liquid.

Blend flour with milk. Combine vegetable cooking liquid, broth, and seasonings; slowly stir in flour mixture. Bring to a boil, stirring constantly; cook 1 minute.

Add chicken, cooked vegetables, mushrooms, and pimiento. Heat thoroughly and serve on rice, toast, or biscuits.

NOTE: Two chicken bouillon cubes and 2 cups of hot water may be used to make broth. Decrease salt to 1 teaspoon.

Menu suggestion

Serve with green beans, molded pineapple and carrot salad, and apple crisp.

Turkey-noodle bake

6 servings

4-ounce package noodles (about 2 cups uncooked) ¼ cup flour 2 cups mushroom liquid and water 2 chicken bouillon cubes ¼ teaspoon salt Pepper, as desired ½ teaspoon poultry seasoning 1 tablespoon chopped pimiento 4-ounce can mushroom stems and pieces, drained, chopped 2 cups cooked turkey, cubed ¾ cup shredded sharp process cheese ■ cup fine dry breadcrumbs 1 tablespoon butter or margarine

Cook noodles as directed on package; drain.

In a saucepan, blend flour with a little of the liquid to make a paste. Gradually stir in remaining liquid. Add bouillon cubes and seasonings.

Bring to a boil, stirring constantly. Reduce heat to simmer; cook 1 minute longer, stirring as needed.

Add pimiento and mushrooms to sauce.

In a 2-quart casserole place half the noodles and half the turkey in layers. Cover with half the sauce. Repeat layers.

Top with cheese; sprinkle with breadcrumbs; dot with fat.

Bake, uncovered, at 350° F. (moderate oven) 30 to 40 minutes or until bubbly and browned.

Variation

Chicken-noodle bake.—Use chicken instead of turkey, and chicken broth instead of water and bouillon cubes.

Menu suggestion

Serve with buttered beets, coleslaw, and have ice cream for dessert.

Chicken pie

6 servings, 9- or 10-inch pie

Filling

3 tablespoons chicken fat, butter, or margarine ¼ cup flour 1¼ cups chicken broth 1 cup milk 1½ teaspoons salt ■ teaspoon pepper ¼ teaspoon poultry seasoning, if desired 2 cups cooked chicken, diced 1■ cups cooked peas and carrots

Pastry for top crust

1 cup flour ¾ teaspoon baking powder ½ teaspoon salt ■ cup shortening 2½ to 3 tablespoons water

Melt fat for the filling in a saucepan; blend in flour. Add broth, milk, and seasonings. Cook, stirring constantly, until thickened.

Add chicken and vegetables; heat thoroughly.

For the pastry, mix flour, with baking powder and salt.

Mix in fat until mixture is crumbly. Add a little water at a time, blending lightly.

Dough should be just moist enough to cling together when pressed into a ball.

Roll dough on a lightly floured surface; shape to fit top of 9- or 10-inch piepan. Make a few small slits near center.

Pour filling into piepan; top with pastry. Turn under pastry edges and press firmly to pan.

Bake at 400° F. (hot oven) 30 minutes, or until browned.

Variation

Turkey pie.—Use turkey broth and cooked turkey in place of chicken broth and cooked chicken.

Menu suggestion

Serve with sliced tomatoes and celery strips and have spicy fruit for dessert.

Braised chicken with vegetables

6 servings

½ cup flour 1 teaspoon salt ¼ teaspoon pepper 3-pound ready-to-cook broiler-fryer chicken, cut up 3 tablespoons fat or oil ¾ cup hot water ½ teaspoon salt 1½ cups sliced carrots 3 cups sliced celery ¾ cup finely chopped onion ¾ cup chopped green pepper

Combine flour, 1 teaspoon salt, and pepper; coat chicken pieces with mixture. Brown chicken in hot fat in large frypan. Drain excess fat from pan. Add water and ½ teaspoon salt. Cover tightly and simmer 45 minutes to 1 hour, or until chicken is almost tender.

Add vegetables and cook 20 to 30 minutes longer, or until vegetables are tender.

Menu suggestion

Serve with rice, lettuce and tomato salad, and fruit for dessert.

Homemade noodles with chicken

6 servings

1 cup flour 1 egg or ¼ cup egg yolks (3 or 4 yolks), slightly beaten 1 tablespoon half-and-half or table cream 1½ teaspoons salt ¾ teaspoon poultry seasoning Pepper, as desired 5 cups chicken broth 3 cups cubed cooked chicken (p. 29) Paprika Parsley

Combine first three ingredients thoroughly and form into a ball. Do not knead. Divide into two parts. Roll each part on lightly floured surface until paper thin. Allow dough to dry 5 to 10 minutes.

With a thin sharp knife, cut dough into strips of desired width and length.

Add seasonings to broth; bring to a boil. Add noodles and boil 9 to 12 minutes, or until tender. Add chicken and continue cooking only until chicken is hot. Sprinkle with paprika and garnish with parsley.

NOTE: One chicken bouillon cube and 1 cup of water may be used for each cup of broth; decrease salt to taste.

Timesaver

Use 1½ cups uncooked packaged noodles instead of making noodles.

Menu suggestion

Serve with broccoli, tossed vegetable salad, and brownies.

Fish

Fish may be cooked by any of the basic methods with excellent results. Fish should not be overcooked; cook only until it flakes easily when tested with a fork. This will leave the fish moist and tender and will bring out its flavor.

Pan-fried fish fillets or steaks

6 servings

2 pounds fish fillets or steaks, fresh or frozen ¼ cup milk 1 egg, beaten 1 teaspoon salt Pepper, as desired 1½ cups fine dry bread, cereal, or cracker crumbs Fat or oil

Thaw frozen fish. Cut fish into 6 portions.

Combine milk, egg, salt, and pepper. Dip fish in milk mixture and roll in crumbs.

Place fish in a single layer in hot fat in a 10-inch frypan. Fry over moderate heat 4 to 5 minutes, or until brown. Turn carefully. Fry 4 to 5 minutes longer, or until fish are brown and flake easily when tested with a fork. Drain on absorbent paper.

Variation

Deep-fat fried fish fillets or steaks.—Prepare fish as for pan-fried fish. Fill fry kettle one-third full of fat; heat to 350° F.

Place fish in a single layer in a fry basket. Fry 3 to 5 minutes, or until fish are brown and flake easily when tested with a fork. Drain on absorbent paper.

TIMETABLE FOR COOKING FISH

[12] Turn once.

Menu suggestion

Serve with tartar sauce, baked potatoes, snap beans, tossed green salad, and upside-down cake.

Salmon loaf

6 servings

1 can (1 pound) salmon ½ cup milk 3 cups soft breadcrumbs ¼ cup butter or margarine, melted ■ cup salmon liquid 3 egg yolks, beaten 2 tablespoons finely chopped green pepper 2 tablespoons finely chopped onion 1 tablespoon lemon juice ■ teaspoon pepper 3 egg whites, stiffly beaten

Drain salmon; save the liquid. Flake salmon.

Heat milk. Add breadcrumbs and butter or margarine and let stand 5 minutes. Add salmon liquid and beat until smooth. Add egg yolks, green pepper, onion, lemon juice, pepper, and salmon; mix well. Fold in egg whites. Pour into a well-greased 1½-quart loafpan.

Bake at 350° F. (moderate oven) 40 to 50 minutes, or until firm in center. Remove from oven and let stand 5 minutes. Loosen from sides of pan with a spatula and invert on a serving platter. Serve plain or with a sauce.

Menu suggestion

Serve with onion or pea sauce, scalloped potatoes, lettuce salad, and apple crisp.

Broiled pan-dressed fish

6 servings

3 pounds pan-dressed fish, fresh or frozen ¼ cup melted fat or oil ¼ cup lemon juice 1½ teaspoons salt ¾ teaspoon paprika Pepper, as desired

Thaw frozen fish. Clean, wash, and dry fish.

Combine fat and seasonings. Place fish on well-greased broiler pan. Brush fish inside and out with seasoned fat.

Broil about 4 inches from heat 5 to 8 minutes. Turn fish carefully and brush on remaining fat. Broil 5 to 8 minutes longer, or until fish flake easily when tested with a fork.

Menu suggestion

Serve with fried potatoes, spinach, grapefruit salad, and gingerbread.

Baked fish fillets or steaks

6 servings

2 pounds fish fillets or steaks, fresh or frozen 2 tablespoons melted fat or oil 2 tablespoons lemon juice 1 teaspoon salt ½ teaspoon paprika Pepper, as desired

Thaw frozen fish. Cut into 6 portions.

Place fish in a single layer, skin side down, in a well-greased baking dish. Combine remaining ingredients and pour over fish.

Bake at 350° F. (moderate oven) 20 to 25 minutes, or until fish flake easily when tested with a fork.

Menu suggestion

Serve with french-fried potatoes, cabbage, molded vegetable salad, and lemon chiffon pie.

Oven-fried fish fillets or steaks

6 servings

2 pounds fish fillets or steaks, fresh or frozen ½ cup milk 1 teaspoon salt 1½ cups cereal crumbs or toasted fine dry bread crumbs ¼ cup melted fat or oil

Thaw frozen fish. Cut into 6 portions.

Combine milk and salt. Dip fish in milk and roll in crumbs. Place fish in a single layer, skin side down, on a well-greased baking pan. Pour fat over fish.

Bake at 500° F. (extremely hot oven) 10 to 15 minutes, or until fish are brown and flake easily when tested with a fork.

Menu suggestion

Serve with broccoli, potatoes with cheese sauce, lettuce salad, and peach crisp.

Baked stuffed fish

6 servings

1 dressed fish (3 pounds), fresh or frozen Salt and pepper, as desired 3 cups stuffing (p. 28) 2 tablespoons melted fat or oil

Thaw frozen fish. Clean, wash, and dry fish.

Sprinkle inside with salt and pepper. Place fish on a well-greased 18- by 13-inch bake-and-serve platter. Stuff fish loosely. Brush fish with fat.

Bake at 350° F. (moderate oven) 45 to 60 minutes, or until the fish flakes easily when tested with a fork.

NOTE: Fish may be baked without stuffing.

Menu suggestion

Serve with broiled tomatoes, peas and celery, coleslaw, and fruit pie.

Topsy turvy tuna pie

6 servings

1 can (6½ or 7 ounces) tuna 2 tablespoons chopped onion 1 tablespoon tuna oil 1 can (10½ ounces) condensed cream of mushroom soup 2 eggs, beaten ½ cup soft breadcrumbs 6 thin slices lemon or orange 1 package (12 ounces) cornbread or corn muffin mix

Drain tuna; save oil. Flake tuna.

Cook onion in oil until tender. Add soup, eggs, breadcrumbs, and tuna; mix well. Arrange lemon or orange slices on the bottom of a well-greased 10-inch piepan. Pour tuna mixture over fruit slices.

Prepare cornbread mix as directed on package. Spread batter over tuna mixture.

Bake at 400° F. (hot oven) 25 to 30 minutes, or until brown. Remove from oven and let stand 5 minutes. Loosen from sides of pan with a spatula and invert on a serving plate.

Menu suggestion

Serve with stewed okra and tomatoes, celery sticks, brownies, and fruit.

Sardine puff

6 servings

2 cans (3¾ or 4 ounces each) Maine sardines 8 slices white bread 1½ tablespoons butter or margarine ¼ cup chopped green pepper ¾ cup shredded sharp natural Cheddar cheese 3 eggs ½ teaspoon salt ¼ teaspoon dry mustard Pepper, as desired 2 cups milk Paprika

Drain sardines and cut into thirds.

Remove crusts from bread, spread with butter or margarine, and cut bread into ½-inch cubes. Place half the bread cubes in a well-greased 12- by 8- by 2-inch baking dish. Cover with sardines, green pepper, and half the cheese. Top with remaining bread cubes and cheese.

Beat eggs, salt, mustard, and pepper. Add milk and mix well. Pour over bread and sprinkle with paprika.

Bake at 350° F. (moderate oven) 45 to 50 minutes, or until firm in the center. Remove from oven and let stand 5 minutes before serving.

Menu suggestion

Serve with green peas, a relish plate, and orange bavarian cream.

Eggs, cheese, dry beans

Main dishes made with eggs, cheese, or dry beans are economical choices for family meals.

Cooking eggs

For best eating quality, eggs should be cooked with low to moderate heat, for just the right amount of time. If cooking temperature is too high or the egg is cooked too long, the white becomes tough and the yolk mealy.

Caution on Use of Cracked or Soiled Eggs

Cracked or soiled eggs may contain bacteria that can produce food poisoning. For your protection, use cracked or soiled eggs only when they are thoroughly cooked or when the foods in which they are an ingredient are thoroughly cooked.

In this publication, a warning note is given with each recipe in which cracked or soiled eggs should not be used.

Scrambled eggs

Break eggs into a bowl. Add milk as follows: For creamy scrambled eggs, add 1 tablespoon milk for each ego; for dry scrambled eggs, add ½ tablespoon milk for each egg. For a product with uniform yellow color, beat mixture enough to blend yolks and whites thoroughly. If you prefer scrambled eggs with flecks of yellow and white, beat only slightly. Season with salt and pepper.

Pour the mixture into a heated frypan in which a little fat has been melted. Cook slowly, stirring occasionally to let the uncooked portion flow to the bottom. Cook until the mixture is set, but still moist.

Or, if preferred, use a double boiler. Melt a little fat in the top part, pour in the egg mixture, place over simmering water in the bottom of the boiler, and cook as above.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Variation

Before cooking the mixture, add herbs, chopped onion, shredded cheese, or small pieces of cooked bacon or ham.

Eggs cooked in shell

Put eggs in a pan; cover them completely with cold water.

For soft-cooked eggs, heat water slowly to simmering. Cover pan and remove from heat. Let stand 3 to 5 minutes; allow the longer time for a larger number of eggs or for a firmer consistency.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

For hard-cooked eggs, bring water to simmering and simmer 20 to 25 minutes. Do not let the water boil. Serve the eggs hot or plunge them at once into cold running water and leave until cold.

NOTE: The green discoloration that sometimes appears between the white and the yolk of a hard-cooked egg results from a chemical reaction, which is harmless. To help prevent this discoloration, cook eggs at low temperature, avoid overcooking, and cool promptly.

Fried eggs

Heat a small amount of fat in a frypan. Bacon or ham drippings may be used for flavor. Break eggs, one at a time, into a saucer, and slip them into the fat. Sprinkle with salt and pepper. Cook over low heat, basting with the fat, until whites are firm.

Or, if you prefer eggs with less fat, use this “fry-poach” method. Melt a little fat in a frypan over low heat—just enough to grease the bottom. Add eggs one at a time, pour in 2 or 3 tablespoons of water, cover pan tightly, and steam until eggs are done. Season before serving.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

French toast

6 servings

4 eggs, beaten ■ cup milk ¼ teaspoon salt 12 slices white bread 2 tablespoons fat or oil

Combine eggs, milk, and salt. Dip each side of bread in egg mixture.

Brown on both sides in fat on a hot griddle—3 to 4 minutes on each side. Serve immediately.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Variation

Add ½ teaspoon cinnamon or nutmeg to egg mixture before dipping bread.

Plain or french omelet

6 servings

6 eggs ¾ teaspoon salt Pepper, as desired 6 tablespoons milk 3 tablespoons butter or margarine

Beat eggs until yolks and whites are well mixed.

Add salt, pepper, and milk.

Melt the fat in a large frypan and pour in the egg mixture.

Cook over moderate heat. As the omelet cooks, lift edges toward center and tip pan so that the uncooked mixture flows under the cooked portion. Continue cooking until bottom is light brown.

Fold one half of the omelet over the other half and serve at once.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Variations

Spread tart jelly or browned mushrooms on half the omelet just before folding.

Sprinkle top of the omelet with shredded cheese, your favorite herbs, or bits of crisp bacon or ham.

Poached eggs

Break eggs into a saucer or custard cup, one at a time, then slip them into gently boiling, salted water—enough water to cover the eggs in a shallow pan.

Reheat water to simmering, take pan from heat, cover. Let stand 5 minutes, or until eggs are of desired firmness. Remove eggs from water and sprinkle with salt and pepper.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Poached eggs supreme

6 servings

1 can (10½ ounces) condensed Cheddar cheese soup 2 tablespoons chopped green pepper ¼ cup process sharp Cheddar cheese spread 6 slices toast 6 eggs

Combine soup and green pepper; heat. Spread cheese on toast. Poach eggs until firm (p. 38). Place eggs on toast and cover with hot soup mixture. Serve immediately.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Menu suggestion

Serve with green beans, fruit salad, and oatmeal cookies.

Deviled eggs

6 servings

6 eggs ¼ cup mayonnaise 1 teaspoon prepared mustard ½ teaspoon vinegar ¼ teaspoon salt White pepper, as desired Paprika

Hard-cook eggs as directed on page 37. Cool eggs under cold running water 5 to 10 minutes. Peel shells from eggs. Cut eggs in half lengthwise. Mash yolks with remaining ingredients except paprika until mixture is smooth. Fill whites with this mixture; sprinkle with paprika.

Variation

Ham-deviled eggs.—Omit salt. Add 1 can (2¼ ounces) deviled ham to yolk mixture.

Baked eggs in hash nests

6 servings

1 can (1 pound, 8 ounces) corned beef hash 6 eggs 2 tablespoons fine dry breadcrumbs, if desired Salt and pepper, as desired 1 tablespoon butter or margarine

Spread hash evenly in a 10½- by 7- by 2-inch baking pan. Form six depressions by pressing the bottom of a ½-cup measure into the hash.

Break an egg into each depression. Sprinkle each egg with breadcrumbs, if desired. Sprinkle with salt and pepper; dot with fat.

Bake at 325° F. (slow oven) 20 to 25 minutes, or until eggs are as firm as desired.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Menu suggestion

Serve with mixed vegetables, lettuce wedges, and brownies.

Cooking cheese

Cheese, like eggs, should be cooked at low temperatures and never overcooked.

Melt cheese over simmering water, or add it to a hot mixture. Add cheese to a sauce after the sauce is cooked and heat only long enough to melt the cheese. Add cheese to an omelet just before folding.

Bake casseroles containing cheese at low to moderate temperatures. To keep cheese toppings from toughening or hardening, cover the cheese with crumbs or add cheese just a few minutes before the casserole comes out of the oven.

Cheese blends more readily with other ingredients and melts more quickly if you shred or dice it first.

Spanish rice with cheese

6 servings

3 slices bacon 1 small onion, finely chopped ¼ cup chopped green pepper ¼ cup chopped celery 1 cup water ½ teaspoon salt ¾ cup packaged precooked rice 2 cups cooked or canned tomatoes 1 teaspoon sugar ¼ teaspoon worcestershire sauce 1 cup shredded Cheddar cheese

Fry bacon in a heavy 2-quart saucepan. Drain bacon on paper. In 1 tablespoon bacon drippings, lightly brown onion, green pepper, and celery.

Add water and salt; bring to a boil. Stir in rice, tomatoes, sugar, and worcestershire sauce. Simmer until rice is just tender, stirring occasionally.

Crumble bacon and stir into rice mixture. Sprinkle cheese over top. Cover and continue cooking over very low heat until cheese is melted, about 5 minutes.

Menu suggestion

Serve with kale, fruit salad, and ice cream.

Pizza

2 pizzas, 14 inches in diameter

1 yeast roll recipe (p. 59) 4 cups shredded cheese (Mozzarella, Muenster, Colby, or process Swiss or Cheddar) 2 cans (8 ounces each) Spanish-style tomato sauce ½ teaspoon oregano ½ cup grated Parmesan cheese

Preheat oven with oven regulator set at broil; leave oven door closed.

Prepare roll dough as directed in recipe, but do not allow to rise. Divide dough into two equal portions; form each into a ball. On a floured surface, roll out each ball of dough into a 14-inch circle. Place on lightly greased pizza pans or baking sheets, turning up edges of dough slightly to form rim.

Sprinkle each pizza with 2 cups shredded cheese. Combine tomato sauce and oregano; spread half the mixture over each pizza. Sprinkle half the Parmesan cheese over each pizza.

Place pizzas in preheated oven and turn oven regulator to 525° F. (extremely hot). Bake 20 to 25 minutes, or until crust is crisp.

NOTE: Any of toppings below may be added before Parmesan cheese. Amounts are for 1 pizza:

1 can (8 ounces) sliced mushrooms, drained ¾ pound ground beef, browned and drained ¼ pound pepperoni, thinly sliced ¾ pound fresh pork sausage, browned and drained

Menu suggestion

Serve with mixed vegetable salad and fruit for dessert.

Macaroni with cheese sauce

6 servings

¼ cup butter or margarine ¼ cup flour ½ teaspoon salt 2 cups milk ½ teaspoon mustard 1½ cups cut-up processed Cheddar cheese 3 cups cooked macaroni

Melt fat and mix in flour and salt. Add milk slowly, stirring constantly, until sauce starts to boil. Lower heat and cook 3 minutes, or until thick.

Add mustard and cheese. Stir over low heat until cheese softens.

Mix in cooked macaroni and heat through.

Menu suggestion

Serve with broiled tomatoes, asparagus, lettuce, and apple crisp.

Baked cheese fondue

6 servings

12 slices white bread ¾ pound process Cheddar cheese, thinly sliced 3 eggs, beaten 3 cups milk ½ teaspoon salt ¼ teaspoon pepper Sage, as desired 1 tablespoon butter or margarine

Grease an 8- by 12- by 2-inch baking dish. Trim crusts from bread. Lay 6 slices in dish; cover with cheese. Top with remaining bread. Combine eggs and milk. Add seasonings and pour over bread. Dot with fat.

Bake at 350° F. (moderate oven) 45 minutes to 1 hour, or until set.

Variation

Place a layer of ¾ cup ground cooked ham on top of cheese before topping with bread.

Menu suggestion

Serve with peas, coleslaw, and apple pie.

Cooking dry beans

Dry beans need soaking before cooking. Use 2½ cups water for 1 cup of blackeye beans (blackeye peas, cowpeas), Great Northern beans, and lima beans. Use 3 cups water for 1 cup of kidney beans, pea (navy) beans, and pinto beans.

To soak them quickly, boil beans 2 minutes, remove from heat, and let stand 1 hour. Or if you prefer, boil beans 2 minutes and let them stand overnight.

Cook the beans in the soaking water. Add 1 teaspoon salt for 1 cup of beans; boil gently for the time given below. One cup of uncooked beans yields about 2½ cups cooked beans.

Approximate cooking time Kind of beans (hours)

Blackeye (blackeye peas, ½ cowpeas). Great Northern 1 to 1½ Kidney 2 Lima 1 Pea (navy) 1½ to 2 Pinto 2

Dry beans will cook more quickly if you add baking soda to the water before soaking. If tap water is of medium hardness, adding ■ teaspoon soda to the water for each cup of dry beans reduces cooking time about one-fourth. Measure soda exactly; too much soda affects flavor and nutritive value of beans.

To reduce foaming when cooking dry beans, add 1 tablespoon meat drippings or other fat to the cooking water for each cup of beans.

Cooked dry beans may be seasoned and eaten without further cooking, or they may be baked, or combined with other foods.

If acid ingredients like tomatoes, catsup, or vinegar are included in the recipe, add them after the beans are tender. Acids prevent softening of the beans.

Boston baked beans

6 servings

2 cups dry navy beans 6 cups (1½ quarts) water ¼ pound salt pork, cut in chunks or slices 1½ teaspoons salt ¼ cup brown sugar, packed 1 teaspoon dry mustard 2 teaspoons chopped onion ½ cup dark molasses

Boil beans in water 2 minutes. Soak 1 hour, or overnight if preferred.

Add salt pork and salt to beans and simmer until beans are tender, about 1½ hours. Drain; save ½ cup liquid. Place beans in a 3-quart casserole.

Combine bean cooking liquid, brown sugar, mustard, onion, and molasses. Pour over beans. Bake uncovered at 350° F. (moderate oven) 1 hour, or until beans are lightly browned on top and of desired consistency.

Menu suggestion

Serve with frankfurters or cold cuts, coleslaw, and baked apples.

Vegetables

Knowing how to prepare vegetables to retain their nutritive value and appetite appeal is a test of any good cook. To help you improve your skill with vegetables, here are some cooking tips—

• Boil vegetables in as little water as possible; losses in vitamins and minerals will be less, the less water you use. Serve the cooking liquids with your vegetables, or make them into sauces, gravies, or soups.

• Cook vegetables until just tender, and serve them immediately; they will taste better and retain more nutrients.

• Trim leafy vegetables like lettuce and cabbage sparingly. Use the dark outer leaves—they are especially rich in nutrients. Remove woody midribs from kale leaves—there is little nutritive loss and the kale cooks more uniformly.

Fresh vegetables

Preparing for cooking

Wash vegetables thoroughly. Use plenty of water for leafy greens; wash several times, lifting vegetables from the water.

Remove bruised, wilted, or tough parts; trim sparingly.

Soak fresh brussels sprouts and broccoli in cold salt water (2 teaspoons salt for each quart of water) 30 to 60 minutes to remove any insects.

Cooking times

In using the Boiling Guide for Fresh Vegetables on the following page, remember that vegetables may require shorter or longer cooking time than given, the exact time depending on quality and variety of vegetable. The altitude at which you live will also affect cooking times; you can shorten the time by cutting, slicing, dicing, or coarsely shredding vegetables.

Boiling fresh vegetables

Bring salted water to a boil. One-half to 1 cup water usually is enough for 6 servings of young, tender vegetables. Older root vegetables that need longer cooking may require water to cover. Spinach and other greens need only the water clinging to their leaves from washing if cooked over low heat in a pan with a tight-fitting lid. Tomatoes can be cooked in their own juice.

Add vegetable. Cover, and quickly bring water back to a boil. Reduce heat and cook gently until vegetable is just tender. Start timing after water returns to boiling.

Frozen and canned vegetables

Frozen.—Cook frozen vegetables according to package directions. For uniform cooking, thaw leafy vegetables just enough to separate the leaves before you put them in boiling water. Partly thaw corn on the cob before cooking it. If necessary, separate pieces of frozen vegetables with a fork during cooking.

Canned.—Commercially canned vegetables need reheating only. If liquid is not served with the vegetable, save it for other uses. (See Ways to Use Leftovers, p. 75.)

Unless you are absolutely sure home-canned vegetables have been processed correctly, bring them to a rolling boil. Then cover and boil for at least 10 minutes. Boil spinach and corn 20 minutes. If food looks spoiled, foams, or has an off-odor during heating, destroy it.

Serving boiled vegetables

Hot, seasoned.—Any vegetable or a combination of two or more.

Before cooking, add a pinch of an herb, such as marjoram or thyme. Or after cooking, season with butter, margarine, or drippings—or with salad oil and lemon juice, horseradish, or garlic. Or sprinkle cooked vegetables with herb vinegar or crumbled bacon.

Mashed.—Potatoes, sweetpotatoes, turnips, rutabagas, kohlrabi, carrots, winter squash.

Drain and mash cooked vegetable. Add hot milk or cream to moisten if needed. Season with salt, pepper, and butter or margarine. Beat until fluffy.

Creamed.—Peas, carrots, celery, cabbage, asparagus, broccoli, potatoes, snap beans, onions, lima beans, cauliflower, spinach.

For 6 servings, combine 3 cups drained cooked vegetable with 1½ cups medium white sauce (p. 57); heat. You may prefer thin white sauce with potatoes or lima beans.

For quick creamed vegetables, pour 1 can (10½ ounces) undiluted condensed soup—Cheddar cheese or cream of celery or mushroom—over 3 cups drained cooked vegetable; heat.

BOILING GUIDE FOR FRESH VEGETABLES

Boiling time Vegetable (minutes)

Asparagus: Whole 10 to 20 Tips 5 to 15 Beans: Lima 25 to 30 Snap, 1-inch pieces 12 to 16 Beets: Young, whole 30 to 45 Older, whole 45 to 90 Sliced or diced 15 to 25 Beet greens, young 5 to 15 Broccoli, heavy stalks, split 10 to 15 Brussels sprouts 15 to 20 Cabbage: Shredded 3 to 10 Quartered 10 to 15 Carrots: Young, whole 15 to 20 Older, whole 20 to 30 Sliced or diced 10 to 20

Cauliflower: Separated 8 to 15 Whole 15 to 25 Celery, cut up 15 to 18 Chard 10 to 20 Collards 10 to 20 Corn, on cob 5 to 15 Kale 10 to 15 Okra 10 to 15 Onions 15 to 30 Parsnips: Whole 20 to 40 Quartered 8 to 15 Peas 12 to 16 Potatoes: Whole, medium size 25 to 40 Quartered 20 to 25 Diced 10 to 15 Rutabagas, pared, cut up 20 to 30 Spinach 3 to 10 Squash: Summer, sliced 8 to 15 Winter, cut up 15 to 20 Sweetpotatoes, whole 35 to 55 Tomatoes, cut up 7 to 15 Turnips: Cut up 10 to 20 Whole 20 to 30 Turnip greens 10 to 30

Chilled, in salads.—Chill cooked vegetables and marinate them in sweet french or italian dressing. See recipes on page 53.

With a sauce.—Suggestions for vegetable and sauce combinations follow. Sauce recipes begin on page 57.

• Asparagus—mock hollandaise sauce, lemon-butter sauce, egg sauce.

• Green beans—quick mushroom or celery sauce.

• Broccoli—sour cream sauce, lemon-butter sauce, mock hollandaise sauce.

• Cauliflower—lemon-butter sauce, cheese sauce.

• Peas—onion sauce, quick mushroom or celery sauce.

• Potatoes—sour cream sauce, cheese sauce.

• Spinach—lemon-butter sauce, mock hollandaise sauce, egg sauce.

• Sweetpotatoes—honey-orange sauce.

Panned vegetables

Panning is a good way to cook cabbage, carrots, or corn.

For 6 servings, use 1½ quarts finely shredded cabbage or 1 quart cut corn or thinly sliced carrots.

Heat 1½ to 2 tablespoons butter, margarine, meat drippings, or oil in a heavy pan over moderate heat. Add vegetable and sprinkle with ½ teaspoon salt. Add 3 tablespoons water (6 tablespoons for corn) and cover pan tightly to hold in steam.

Cook over low heat until vegetable is tender; stir occasionally to prevent sticking. Cabbage will require 6 to 8 minutes, carrots about 10 minutes, and corn 15 to 18 minutes.

Variation

Add finely chopped onion or onion juice before cooking. Or add bits of crumbled crisp bacon or diced ham to cooked vegetable.

Spinach souffle

6 servings

1 package (10 ounces) frozen chopped spinach 1 tablespoon finely chopped onion ¼ cup fat or oil ■ cup flour 1½ cups milk 1½ teaspoons salt ¼ teaspoon pepper 4 eggs, separated ½ teaspoon cream of tartar

Cook spinach as directed on package, but omit salt. Drain.

Lightly brown onion in fat in a heavy 1-quart saucepan. Blend in flour. Slowly stir in milk. Bring to a boil, stirring constantly. Reduce heat and cook 1 minute more, stirring constantly. Add salt, pepper, and spinach.

Beat egg yolks slightly; stir in a little of hot mixture. Then stir egg yolks into remaining hot mixture and cook 1 minute more. Cool slightly.

Add cream of tartar to egg whites and beat until stiff but not dry. Fold in spinach mixture. Pour into a greased 2-quart casserole. Set casserole in a pan of hot water.

Bake at 350° F. (moderate oven) about 1¼ hours. Souffle is done when a knife inserted in the center comes out clean.

Broiled tomatoes

6 servings

3 large or 6 small ripe tomatoes Salt and pepper, as desired 2 teaspoons butter or margarine 2 tablespoons fine dry breadcrumbs

Wash tomatoes; cut off stem ends. Cut large tomatoes in 1-inch slices; cut small tomatoes in half crosswise.

Place cut side up on broiler rack. Sprinkle with salt and pepper. Dot each slice with fat and sprinkle with breadcrumbs.

Broil until tomatoes are soft and crumbs lightly browned, 5 to 7 minutes.

Sweetpotatoes in orange shells

6 servings

3 oranges 1 can (1 pound) sweetpotatoes, undrained 2 tablespoons butter or margarine, melted 3 tablespoons brown sugar, packed ½ teaspoon salt ¼ cup flaked coconut 6 miniature marshmallows

Squeeze oranges; save juice.

Remove membranes from orange shells.

Mash sweetpotatoes. Blend in 3 tablespoons orange juice, fat, brown sugar, and salt. Stir in coconut.

Spoon sweetpotato mixture into the orange shells. Place in a shallow baking pan.

Bake at 350° F. (moderate oven) for 20 to 30 minutes, or until lightly browned on top.

Top with marshmallows and bake about 5 minutes longer to melt and brown marshmallows.

Hungarian cabbage

6 servings

2 slices bacon 2 quarts coarsely shredded cabbage (about 1 pound) ¾ teaspoon salt Pepper, as desired 2 tablespoons vinegar 2 tablespoons water

Fry bacon until crisp; remove from pan. Add remaining ingredients to fat in pan.

Cover tightly and cook over low heat, stirring occasionally, for 20 to 25 minutes. Cabbage should be tender but crisp.

Crumble bacon over top before serving.

Stewed okra and tomatoes

6 servings

1 small onion, chopped 2 tablespoons fat or oil 1 package (10 ounces) frozen okra 1 can (1 pound) tomatoes ½ teaspoon salt ¼ teaspoon pepper

Cook onion in fat in saucepan over moderate heat until lightly browned.

Add remaining ingredients and cook until okra is tender and mixture thickens, 10 to 15 minutes. Stir occasionally to prevent sticking.

Quick cauliflower au gratin

6 servings

2 packages (10 ounces each) frozen cauliflower 1 can (10½ ounces) condensed Cheddar cheese soup 2 tablespoons fine dry breadcrumbs 1 teaspoon melted butter or margarine

Cook frozen cauliflower according to package directions.

Drain cauliflower and place in a greased 1-quart casserole. Pour undiluted soup over cauliflower. Mix crumbs with fat and sprinkle over top. Bake at 350° F. (moderate oven) 20 to 30 minutes, or until sauce bubbles and crumbs are brown.

NOTE: Two pounds of fresh cauliflower, separated into small flowerets and cooked until tender, can be used instead of frozen cauliflower.

Variation

Quick spinach au gratin.—Use 2 packages (10 ounces each) frozen chopped spinach. Crumble 6 slices crisp fried bacon over mixture before topping with crumb mixture.

Lima bean creole

6 servings

2 packages (10 ounces each) frozen lima beans 6 slices bacon ¼ cup finely chopped onion 2 tablespoons chopped green pepper ½ teaspoon salt Pepper, as desired 2 cups cooked or canned tomatoes

Cook beans as directed on package; drain.

Fry bacon; drain on absorbent paper. In 2 tablespoons bacon drippings, brown onion and green pepper. Crumble bacon. Add browned onion and green pepper, bacon, seasonings, and tomatoes to beans. Cover and simmer gently 15 minutes.

Variations

Green bean creole.—Use 2 packages (10 ounces each) frozen cut green beans instead of lima beans.

Eggplant creole.—Use 1 medium-size eggplant, pared and cubed, instead of beans. Do not cook eggplant before combining with other ingredients. Increase salt to 1 teaspoon. Cook 15 to 20 minutes, until eggplant is tender.

Scalloped zucchini squash

6 servings

6 cups thinly sliced zucchini squash 1 cup boiling water ¾ cup medium white sauce (p. 57) 2 eggs, beaten 1 teaspoon salt ½ teaspoon worcestershire sauce 1 teaspoon finely chopped onion ¼ cup fine dry breadcrumbs 1 tablespoon butter or margarine, melted

Cook squash in boiling water until tender, about 5 minutes. Drain.

Make white sauce.

Stir a little hot white sauce into beaten eggs; then gradually stir eggs into remaining sauce. Stir in salt, worcestershire sauce, onion, and cooked squash.

Put in a greased 1-quart casserole. Mix breadcrumbs with fat; sprinkle over squash mixture. Bake at 325° F. (slow oven) about 35 minutes.

Ham-seasoned green beans

6 servings

1½ pounds green beans, broken into short pieces 2 small onions, quartered ½ stalk celery, sliced About 2 ounces cooked ham, cut into bite-sized pieces 2 teaspoons salt Pepper, as desired ½ cup water 1 tablespoon butter or margarine

Place beans in a 2-quart saucepan. Add remaining ingredients. Simmer until beans are tender, 12 to 20 minutes.

NOTE: Instead of fresh green beans, use 2 packages (10 ounces each) frozen cut green beans.

Harvard beets

6 servings

3 tablespoons cornstarch ■ cup sugar ¾ teaspoon salt 1½ cups beet liquid (or beet liquid plus water) 2 tablespoons vinegar 1½ tablespoons butter or margarine 3 cups sliced cooked or canned beets

Mix cornstarch, sugar, and salt. Blend in beet liquid, vinegar, and fat. Cook over moderate heat, stirring constantly, until thickened.

Add beets to sauce. Let stand 10 minutes, if desired, to blend flavors. Heat to serving temperature.

Eggplant casserole

6 servings

2 cups pared, cubed eggplant 2 tablespoons finely chopped onion ¼ cup water 2 eggs, slightly beaten 2 slices soft bread, torn in very small pieces ½ cup milk 1 teaspoon salt Pepper, as desired 1¼ cups shredded sharp Cheddar cheese

Cook eggplant and onion in unsalted water until eggplant is tender, about 7 minutes; drain. Combine all ingredients except ¼ cup cheese; mix well. Pour into a greased 1-quart casserole. Bake uncovered at 350° F. (moderate oven) 25 minutes. Sprinkle with remaining cheese and bake 5 minutes longer.

Glazed carrots

6 servings

2 tablespoons butter or margarine ¼ cup brown sugar, packed 1 tablespoon water 3 cups cooked carrots, cut in strips

Blend fat, sugar, and water in a heavy fry pan over low heat. Add carrots. Cook over low heat 5 to 10 minutes, turning carrots to coat all sides with sirup. Keep heat low to prevent scorching.

Potato patties

6 patties

2 cups seasoned mashed potatoes 1 egg or 2 egg yolks, slightly beaten 1 tablespoon finely chopped onion 1 tablespoon chopped green pepper 2 tablespoons fat or oil

Combine all ingredients except fat; mix well. Shape into six patties. Brown well in hot fat, about 4 minutes on each side.

NOTE: Leftover mashed potatoes or instant mashed potatoes, prepared according to package directions, may be used in this recipe.

Stuffed baked potatoes

6 servings

6 medium-size baking potatoes 1 package (3 ounces) cream cheese, at room temperature ■ cup milk 1 teaspoon salt ■ cup butter or margarine Paprika

Rub potatoes with a little fat if soft skins are desired. Bake at 425° F. (hot oven) 50 to 60 minutes, or until potato is soft when pressed. Slash tops lengthwise and crosswise. Fold back flaps, scoop out inside, and mash thoroughly.

Soften cream cheese and blend in milk, salt, and fat until smooth and creamy. Add cream cheese mixture gradually to hot potato, blending thoroughly.

Stuff skins with potato mixture. Sprinkle with paprika. Return to oven a few minutes to brown tops.

Green bean-mushroom casserole

6 servings

2 packages (10 ounces each) frozen cut green beans ¼ cup finely chopped onion ¼ cup water 1 teaspoon salt 1 can (10½ ounces) condensed cream of mushroom soup 1 can (4 ounces) mushroom stems and pieces, drained, chopped ½ cup canned french-fried

onion rings

Cook beans and chopped onion in water with salt until beans are tender, 12 to 15 minutes. Drain.

Stir in undiluted soup and mushrooms. Pour into greased 1½-quart casserole. Top with onion rings. Cover and bake at 350° F. (moderate oven) 30 minutes, or until mixture is heated through and top is brown.

Onions in mushroom sauce

6 servings

1½ pounds small yellow onions 1 cup water 1 teaspoon salt 1 can (10½ ounces) condensed cream of mushroom soup Parsley

Peel and quarter onions. Leave very small onions whole. Simmer onions in salted water 15 to 20 minutes, or until just tender. Drain.

Add undiluted soup and simmer 10 to 15 minutes longer. Garnish with parsley before serving.

Salads and Salad Dressings

What better way to serve a variety of fruits, vegetables, even meats—than in a colorful salad? As an appetizer, a side dish, a dessert, or the main course of your meal, a salad brings lots of goodness to your table. Salads can be light or hearty, depending on the ingredients you choose.

Summertime salads often feature a medley of fresh fruits. Tossed green salads are year-round favorites. Salads made from eggs and potatoes, from seafoods, and from meats and cheeses also deserve a place in your meal planning.

Tips on salad making

Selecting top-quality fruits and vegetables is a good start toward a good salad. Fresh food has eye and taste appeal.

Give salad foods the best care to avoid damage and to keep them fresh. If you prepare salad ingredients ahead of time, store them, without dressing, in the refrigerator.

If you plan to use unpeeled fruits or vegetables in a salad, choose those with smooth, tender, colorful skins.

See page 12 for other pointers on selecting fresh fruits and vegetables. You'll find suggestions for storing them on page 14.

For appetite appeal

Chill ingredients before you mix your salad.

For tossed green salads, tear greens into fairly large pieces. This will give your salad more body.

Always thoroughly drain the greens you use in salads.

Vary your salad greens. Try chicory, escarole, endive, kale, spinach, dandelion greens, romaine, watercress, and chinese cabbage.

Some salad fruits are likely to turn dark on standing; dip these in a little citrus juice.

Drain canned fruits and vegetables before you add them to a salad.

Tips on dressings

Main-dish salads made with meat, fish, poultry, eggs, beans, cheese, or potatoes usually call for a mayonnaise-type dressing, but some are good with french or italian dressing (p. 53).

On vegetable salads and vegetable-fruit combinations, try french, italian, thousand island, or Roquefort or blue cheese dressing (p. 53). Fruit salads taste best with sweet dressings—sweet french, orange-honey, or celery seed dressing ([p. 53]).

Prevent sogginess and wilting by using just enough salad dressing to moisten ingredients. Add dressing to raw vegetable salads at the last minute unless your recipe calls for marinated vegetables.

Salad go-togethers

Some salad combinations are traditional—lettuce and sliced tomatoes, canned peaches and cottage cheese. You can make a variety of salads by sometimes contrasting flavors and textures, sometimes complementing them.

Ingredients that go well together in salads are suggested below.

Fruit salad combinations

6 servings

• Pare and section 2 grapefruit and 3 oranges. For each salad arrange grapefruit and orange sections on a lettuce leaf; garnish with a maraschino cherry half.

• Lightly mix 1½ cups each of cantaloup, honeydew, and watermelon balls or cubes. Serve on crisp salad greens. Allow about ■ cup fruit per serving.

• Drain 1 can (13½ ounces) pineapple tidbits; combine with 3 oranges, pared and sectioned, and 1 banana, sliced. Place on crisp salad greens and sprinkle with ¼ cup chopped walnuts. Allow about ½ cup fruit per serving.

• Lightly mix 2 cups cantaloup cubes; ½ cup fresh blueberries; and 1 large banana, sliced. Serve on crisp salad greens; allow about ½ cup fruit per salad.

• Combine 4 peaches, peeled and sliced; ½ cup halved seedless grapes; ½ cup halved, seeded Tokay grapes; and 1 large banana, sliced. Serve on crisp salad greens; allow about ■ cup fruit per serving.

Vegetable salad combinations

6 servings

• Lightly toss together ½ pound young spinach leaves, torn in bite-size pieces; 2 green onions, thinly sliced; and 4 crisp bacon strips, crumbled. Garnish with 2 hard-cooked eggs, chopped.

• Lightly toss together 2 carrots, thinly sliced; ½ head raw cauliflower, thinly sliced; ½ head lettuce, torn in bite-size pieces; ¼ cup chopped green pepper; and 2 tomatoes, cut in wedges.

• Cook, drain, and chill 1 package (10 ounces) frozen mixed vegetables; lightly toss together with ½ head lettuce, torn in bite-size pieces.

Marinated vegetable salads

6 servings

Asparagus spear salad.—Hard cook 2 eggs; chill. Drain 1 can (1 pound) asparagus spears and marinate overnight in ½ cup sweet french dressing (p. 53). For each salad arrange asparagus spears on a lettuce leaf, top with a strip of canned pimiento, and sprinkle with chopped hard-cooked egg.

Cucumber and onion salad.—Score 2 cucumbers with a fork; pare first, if desired. Slice thinly. Slice ½ medium onion and separate it into rings. Marinate cucumber and onion slices 3 to 4 hours in ½ cup sweet french dressing (p. 53). Serve garnished with tomato wedges.

Green bean salad.—Drain 1 can (1 pound) cut green beans and 1 can (8 ounces) cut wax beans. Thinly slice 1 small onion and separate into rings. Toss beans and onion rings with ½ cup chopped sweet red or green pepper. Marinate overnight in ½ cup sweet french dressing (p. 53).

Three-bean salad.—Drain 8-ounce cans of green beans, wax beans, and kidney beans; continue as directed for green bean salad.

Creamy fruit salad

6 servings

1 package (3 ounces) cream cheese 1 tablespoon sirup from canned mandarin oranges 1 can (11 ounces) mandarin orange sections, drained 1 can (13½ ounces) pineapple tidbits, drained 1 cup miniature marshmallows ■ cup halved, drained maraschino cherries Lettuce

Beat cream cheese with liquid from mandarin oranges until creamy. Add oranges, pineapple, and marshmallows; combine gently but thoroughly. Lightly fold in cherries. Chill. Serve in lettuce cups.

Variation

Frozen fruit salad.—Blend ¼ cup mayonnaise with cream cheese and liquid before adding the fruits. Whip 1 envelope of dessert topping mix as directed on package label. Fold whipped topping and cherries into the fruit mixture. Pour into a 1½-quart mold and freeze overnight. Dip in warm water to unmold.

Molded pineapple-carrot salad

6 servings

1 package (3 ounces) lemon-flavored gelatin 1 cup shredded raw carrots 1 can (10½ ounces) crushed pineapple, drained ¼ cup raisins Lettuce Mayonnaise

Prepare gelatin according to package directions, using pineapple sirup as part of the liquid. Chill until mixture is slightly thickened.

Fold in carrots, pineapple, and raisins; pour into a 1-quart mold. Chill until firm. Serve on lettuce; top with mayonnaise if desired.

Souffle meat salad

6 servings

1 package (3 ounces) lemon-flavored gelatin 1 cup boiling water ½ cup cold water ½ cup salad dressing 2 tablespoons vinegar ¼ teaspoon salt Pepper, as desired ½ cup chopped celery 1 tablespoon chopped parsley 1 tablespoon grated onion 2 cups chopped cooked meat Salad greens

Dissolve gelatin in boiling water. Add cold water, salad dressing, vinegar, salt, and pepper. Beat until smooth. Chill until slightly thickened.

Whip until fluffy. Fold in celery, parsley, onion, and meat. Pour into a 1-quart mold. Chill until firm.

Unmold on salad greens.

Variations

Souffle poultry salad.—Use 2 cups chopped cooked poultry as the meat.

Souffle fish salad.—Use 2 cups flaked canned or cooked fish as the meat.

Menu suggestion

Serve with broiled tomatoes, asparagus, and have apple pie with cheese for dessert.

Stuffed prune salad

6 servings

½ cup creamed cottage cheese 1 to 2 tablespoons milk, if needed 1 to 2 teaspoons grated orange rind, as desired ¼ cup chopped peanuts ¼ teaspoon salt (if peanuts are unsalted) 18 chilled, pitted, cooked prunes Salad greens

If cottage cheese is dry, soften it with milk. Mix in orange rind, 3 tablespoons peanuts, and salt; stuff into prunes.

Arrange prunes on salad greens and sprinkle with rest of peanuts.

Luncheon chef salad bowl

6 main-dish salads

2 medium heads lettuce 8 radishes, thinly sliced 4 green onions, with tops, thinly sliced 3 large ripe tomatoes, cut into 8 wedges each 3 cups cooked ham (about 1 pound), cut into 1-inch cubes 2 cups coarsely shredded Swiss cheese Croutons (p. 56) Salad dressing

Wash and drain lettuce. Reserve outer lettuce leaves; tear remaining lettuce into bite-size pieces. Combine torn lettuce, radishes, and green onions; toss lightly.

Line 6 individual salad bowls with lettuce leaves. For each salad, use 2 cups lettuce mixture and top with 4 tomato wedges, ½ cup ham cubes, and ■ cup shredded cheese. Top with croutons. Serve with dressing of your choice.

Menu suggestion

Serve with garlic bread and have quick cherry cobbler for dessert.

Coleslaw

6 servings

1½ teaspoons salt ½ teaspoon dry mustard White pepper, as desired ¼ cup sugar 2 tablespoons lemon juice 1 tablespoon tarragon vinegar ¼ cup table cream 3 cups coarsely shredded cabbage ¼ cup finely chopped green pepper 1 tablespoon chopped pimiento ½ cup finely chopped celery 2 tablespoons finely chopped onion

Thoroughly mix all ingredients except vegetables.

Combine vegetables; mix well. Gently stir in the dressing. Chill before serving.

Potato salad

6 servings

½ cup mayonnaise 1 teaspoon dry mustard 2½ teaspoons salt 2 tablespoons finely chopped onion 2 tablespoons chopped green pepper ¾ cup finely chopped celery ¼ cup sweet pickle relish 1 tablespoon chopped pimiento 6 medium-size boiled potatoes, diced 3 hard-cooked eggs, chopped

Combine ingredients except potatoes and eggs; mix thoroughly. Pour this mixture over potatoes and mix gently. Add chopped eggs. Chill several hours before serving.

Variation

Pea salad.—Use 1 package (10 ounces) frozen peas, cooked and drained, or 1 can (1 pound) peas, drained, in place of potatoes. Reduce salt to 1 teaspoon. Add 1 cup process Cheddar cheese cubes.

Basic french dressing

About 1 cup

■ cup salad oil 1 tablespoon tarragon vinegar 2 tablespoons lemon juice 1½ teaspoons salt ½ teaspoon paprika ½ teaspoon dry mustard White pepper, as desired

Thoroughly mix all ingredients. Chill. Shake well just before serving.

Variations

Sweet french dressing.—Increase vinegar to 2 tablespoons and add ¼ cup sugar.

Italian dressing.—Use ¼ teaspoon white pepper. Add ¼ cup finely chopped onion, 1 teaspoon finely chopped garlic, 2 tablespoons sugar, ½ cup catsup, and ½ teaspoon oregano. Refrigerate, covered, overnight to blend flavors. Strain to remove onion and garlic before serving. About 1½ cups.

Roquefort (blue) cheese dressing

About 1 cup

1 cup mayonnaise 1 package (4 ounces) Roquefort or blue cheese, crumbled 2 tablespoons half-and-half or table cream ½ teaspoon tabasco sauce

Mix all ingredients.

Refrigerate until used.

Orange-honey french dressing

About 1¼ cups

¼ cup orange juice frozen concentrate 1 tablespoon vinegar ¼ cup honey ½ teaspoon dry mustard ½ teaspoon salt ■ cup salad oil

Thoroughly mix all ingredients except salad oil.

Add the oil slowly while beating constantly with rotary or electric beater.

Refrigerate until used.

Celery seed dressing

About 1 cup

■ cup sugar 2 tablespoons lemon juice 1 tablespoon tarragon vinegar 1½ teaspoons salt ½ teaspoon paprika ½ teaspoon dry mustard 1 teaspoon celery seed ■ cup salad oil

Thoroughly mix all ingredients except salad oil.

Add the oil slowly while beating constantly with rotary or electric beater.

Refrigerate until used.

Thousand island dressing

About 2 cups

1 cup mayonnaise ¼ cup sweet pickle relish 2 tablespoons chili sauce 1 tablespoon chopped green pepper 1 tablespoon finely chopped onion 1 hard-cooked egg, finely chopped

Mix all ingredients except the egg. Gently mix in the chopped egg.

Refrigerate until used.

Soups

Steaming hot, hearty soups and chowders make delicious dishes for luncheon or supper. When they contain substantial amounts of fish, meat, milk, dry beans or peas, they are filling enough to be the main part of your meal. Or you can serve soup with a salad or a sandwich.

Turkey-vegetable soup

6 servings

1 small onion, chopped 2 tablespoons butter or margarine 2 cups water 2 chicken bouillon cubes 2 cups cooked turkey, diced ½ cup celery tops and pieces 1½ cups diced potatoes 1 cup diced carrots 2½ cups milk 2 tablespoons flour 1 teaspoon salt ■ teaspoon pepper

Cook onion in fat until tender. Add water, bouillon cubes, turkey, and vegetables.

Boil gently, covered, until vegetables are tender.

Stir a little of the milk into the flour until mixture is smooth; add remaining milk, salt, and pepper. Add milk mixture to soup.

Simmer, stirring occasionally to prevent sticking, until soup is slightly thickened.

Variation

Chicken-vegetable soup.—Use chicken instead of turkey, and chicken broth instead of water and bouillon cubes.

Menu suggestion

Serve with a cucumber salad, toast, and cherry pie.

Hearty vegetable soup

6 servings

1 cup cooked beef, cut in small pieces 6 cups beef broth 2 cups fresh or canned tomatoes 1 cup diced potatoes ¾ cup diced carrots ½ cup sliced onion 3 cups other uncooked vegetables (green peas, chopped cabbage, diced celery, cut green beans, chopped green pepper, sliced okra, diced turnips, cut corn) 1½ teaspoons salt ■ teaspoon pepper

Combine beef and broth in a large saucepan. Add remaining ingredients.

Cook, covered, about 35 minutes, or until vegetables are tender.

NOTES: In place of beef broth use 6 beef bouillon cubes and 6 cups water. (Liquid from canned or cooked vegetables may replace some of the water.)

Canned or leftover vegetables may be used instead of uncooked vegetables. Add to soup during last few minutes of cooking.

Menu suggestion

Serve with toasted cheese sandwiches and have fruit gelatin for dessert.

Bean soup

6 servings

1½ cups dry beans 7 cups water Ham pieces or ham bone 1 small onion, chopped 2 celery stalks, chopped 1 teaspoon salt ¼ teaspoon pepper

Boil beans in the water for 2 minutes; remove from heat. Let soak in cooking water 1 hour, or overnight if preferred.

Add remaining ingredients. Simmer, covered, until beans are soft, about 2 to 3 hours.

Remove ham bone and partially mash beans before serving soup.

Menu suggestion

Serve with coleslaw, cornbread, and apple pie with cheese.

New England fish chowder

6 servings

1 pound fish fillets or steaks, fresh or frozen 2 tablespoons chopped bacon or salt pork ½ cup chopped onion 2½ cups diced potatoes 1½ cups boiling water 1 teaspoon salt Pepper, as desired 2 cups milk 1 tablespoon butter Chopped parsley

Thaw frozen fish. Remove skin and bones. Cut fish into 1-inch pieces.

Fry bacon or salt pork in a 3-quart saucepan until crisp. Add onion and cook until tender. Add potatoes, water, salt, pepper, and fish. Cover; simmer 15 to 20 minutes, or until potatoes are tender.

Add milk and butter. Heat. Garnish with parsley.

Menu suggestion

Serve with crackers, fruit salad, and chocolate cake.

Manhattan fish chowder

6 servings

1 pound fish fillets or steaks, fresh or frozen ¼ cup chopped bacon or salt pork ½ cup chopped onion 2 cups boiling water 1 can (1 pound) tomatoes 1 cup diced potatoes ½ cup diced carrots ½ cup chopped celery ¼ cup catsup 1 tablespoon worcestershire sauce 1 teaspoon salt ¼ teaspoon pepper ¼ teaspoon thyme Chopped parsley

Thaw frozen fish. Remove skin and bones. Cut fish into 1-inch pieces.

Fry bacon or salt pork in a 3-quart saucepan until crisp. Add onion and cook until tender. Add water, vegetables, catsup, and seasonings except parsley. Cover and simmer 40 to 45 minutes, or until vegetables are tender.

Add fish. Cover and simmer about 10 minutes longer, or until fish flake easily when tested with a fork. Garnish with parsley.

Menu suggestion

Serve with marinated green bean salad, peaches, and oatmeal cookies.

Croutons

6 servings

3 slices bread 2 tablespoons softened butter or margarine ¼ teaspoon garlic salt Paprika

Trim crusts from bread. Blend butter or margarine with garlic salt; spread on both sides of bread. Cut bread into cubes; place them on baking sheet and sprinkle with paprika.

Bake at 300° F. (slow oven) until crisp and golden brown, about 20 to 30 minutes.

Serve on soups or salads or as a soup accompaniment.

Variation

Cheese croutons.—Mix bread cubes lightly with ½ cup grated Parmesan cheese before placing on baking sheet.

Creamy potato soup

6 servings

5 cups raw diced potatoes ¼ cup finely chopped onion 1½ cups water 3 cups potato cooking liquid and milk 2 tablespoons butter or margarine 2 teaspoons salt Pepper, as desired Paprika or chopped parsley

Cook potatoes and onion in water in a covered saucepan until potatoes are tender, about 15 minutes. Drain and mash potatoes; save cooking liquid.

Measure liquid; add enough milk to make 3 cups.

Slowly stir liquid into potatoes; add fat and seasonings.

Simmer a few minutes to blend flavors. Garnish with paprika or parsley.

Menu suggestion

Serve with tossed vegetable salad, cheese muffins, and fresh fruit.

Cream of broccoli soup

6 servings

1 package (10 ounces) frozen chopped broccoli 1 tablespoon finely chopped onion ¼ cup flour 3 cups vegetable cooking liquid and milk 1 tablespoon butter or margarine 1½ teaspoons salt Pepper, as desired 1 hard-cooked egg, sliced, if desired

Cook broccoli according to package directions, but omit salt and add onion. Drain; save cooking liquid.

Mix flour with part of milk mixture until smooth. Add remaining liquid to broccoli. Stir in flour mixture, fat, and seasonings.

Cook over moderate heat, stirring occasionally, until soup is slightly thickened and flavors are blended. Garnish with slices of hard-cooked egg, if desired. Serve with croutons (see recipe on this page).

Menu suggestion

Serve with meat sandwiches and baked apples.

Sauces and Gravies

Sauces and gravies are not difficult if you begin with these basic recipes. As you become more expert, you can develop your own variations.

White sauce

1 cup

Thin _Medium_ _Thick_ Fat (tablespoons) 1 1 or 2 2 or 3 Flour (tablespoons) 1 2 3 or 4 Salt (teaspoon) ¼ ¼ ¼ Milk (cup) 1 1 1

Melt butter, margarine, or other fat in heavy saucepan. Blend in flour until smooth. Add salt. Add milk slowly, stirring rapidly to prevent lumping. Bring mixture to a boil, stirring constantly. Reduce heat and cook 1 minute, stirring constantly. Remove from heat.

Thin white sauce is used in cream soup, gravy, and in creamed and scalloped vegetables, eggs, fish, and meat.

Medium white sauce is also used in gravy and in creamed and scalloped vegetables, eggs, fish, and meat.

Thick white sauce is used in hollandaise sauce and as a binder for croquettes and souffles.

Variations

Cheese sauce.—Add 1 cup of finely grated cheese to 1 cup hot white sauce, either thin or medium. Stir until cheese is melted, taking care not to overcook.

Egg sauce.—To 1 cup of hot medium white sauce add: 3 chopped, hard-cooked eggs; 1 tablespoon lemon juice; a few drops of yellow food coloring, if desired. Stir.

Onion sauce.—Use proportions for medium white sauce. Brown ½ cup of finely chopped onion in fat before adding flour; then continue as directed above. Add white pepper, as desired.

Gravy

For a thin gravy use 1 tablespoon each of flour and fat or drippings to each cup of liquid; for a medium gravy use 2 tablespoons of flour and 1 or 2 tablespoons of fat or drippings, as desired. If drippings are scant, add a bouillon cube or a little meat extract to the liquid.

METHOD 1.—_Use with fat or with drippings containing only fat and browned crusty bits._ Measure fat or drippings. Stir flour into fat; brown over low heat. Add liquid slowly, stirring constantly. Cook until thickened, stirring occasionally. Season to taste.

METHOD 2.—_Use with fat or drippings containing a considerable amount of liquid._ Measure drippings; if necessary add water to make desired amount of liquid. Heat. Combine flour with an equal amount of cold water by stirring or shaking until smooth. Stir slowly into hot liquid. Cook until thickened, stirring occasionally. Season to taste.

Tartar sauce

About ¾ cup

½ cup mayonnaise or salad dressing 1 tablespoon chopped olives 1 tablespoon chopped onion 1 tablespoon chopped parsley 1 tablespoon chopped sweet pickle

Combine all ingredients and mix well. Chill. Serve with fish.

Honey-orange sauce

About 1 cup

■ cup honey 1 tablespoon cornstarch 1 teaspoon grated orange rind ½ cup orange juice ¼ cup water 2 tablespoons butter or margarine

Combine honey, cornstarch, and orange rind in a heavy saucepan. Stir in orange juice and water. Bring to a boil; add fat and blend well. Cool slightly. (Sauce thickens as it cools.)

Can be spooned over warm gingerbread or other desserts.

Sour cream sauce

About 1 cup

1 cup sour cream 1 tablespoon chopped fresh or frozen chives or green onion tops ¼ teaspoon salt 3 drops worcestershire sauce White pepper, as desired

Combine all ingredients thoroughly at least 2 hours before serving. Refrigerate. Serve at room temperature or slightly chilled.

Can be served with broccoli or baked potatoes.

Quick vegetable sauce

About 2 cups

1 can (10½ ounces) condensed cream of vegetable, celery, or mushroom soup ½ cup half-and-half or table cream

Combine ingredients and heat.

Serve over vegetables, meats, or fish.

Mock hollandaise sauce

About 1 cup

1 cup thick white sauce, made with 3 tablespoons flour and 3 tablespoons fat (p. 57) 2 egg yolks, slightly beaten 2 tablespoons lemon juice

Make 1 cup of thick white sauce. Add a little hot white sauce to beaten egg yolks; then stir egg mixture into remaining white sauce. Cook 1 minute over low heat.

Stir in lemon juice. Serve immediately.

Can be served with asparagus, broccoli, or spinach.

NOTE: _Use yolks from clean, sound-shelled eggs in this recipe._

Lemon-butter sauce

About ■ cup

¼ cup melted butter or margarine ¾ teaspoon salt ¾ teaspoon paprika 1 tablespoon lemon juice 2 teaspoons prepared horseradish

Mix all ingredients well.

Serve hot over vegetables or fish.

Breads and Sandwiches

Hot breads

Bake a batch of homemade bread or yeast rolls, and watch tired appetites perk up. Surprise your family with hot biscuits or muffins.

For a leisurely Sunday breakfast, make waffles or pancakes.

Before using the recipes for breads, see the section on ingredients and measurements (p. 16).

Yeast rolls

18 to 24 rolls

1 package active dry yeast or 1 cake compressed yeast ¼ cup warm water (about 110° F.) ¾ cup hot milk ¼ cup shortening or oil ¼ cup sugar 1¼ teaspoons salt 1 egg About 4 cups flour

Dissolve yeast in water. Mix milk, fat, sugar, and salt in a large mixing bowl. Cool to lukewarm.

Stir in egg and yeast. Add 2 cups flour and beat until smooth. Gradually stir in more flour until dough leaves sides of bowl.

Turn dough out onto lightly floured surface and knead until dough is smooth and elastic.

Place in a lightly greased bowl and turn over once to grease upper side of dough. Cover and let rise in a warm place (80° to 85° F.) until almost double in bulk, 1 to 1¼ hours. Dough should rise until a light touch leaves a slight depression. Press the dough down into the bowl to remove air bubbles.

To make plain rolls, divide dough into small pieces and roll into balls about 1½ inches in diameter. Place in a shallow greased pan with sides touching—or 1 inch apart if you prefer crusty sides.

Cover loosely and let rise in a warm place until double in bulk, 45 minutes to 1 hour.

Bake at 400° F. (hot oven) 15 to 20 minutes.

Brush rolls with melted butter or margarine after removing them from the oven.

Variations

Crescent rolls.—Divide dough into three portions. On a lightly floured surface, roll out each portion into a circle about 10 inches in diameter. Brush with melted butter or margarine. Cut each circle into 6 wedges; roll wedges up tightly, beginning at wide end. Place on greased baking sheet with points down; curve ends to form crescents. Let rise and bake.

Cinnamon-nut rolls.—Roll dough out on lightly floured surface into a rectangle about ¼-inch thick. Brush with melted butter or margarine. Sprinkle with a mixture of ½ cup sugar and 2 teaspoons cinnamon. Press ½ cup chopped nuts into dough. Roll as for jelly roll; seal edge. Cut into ¾-inch slices. Place close together, cut side down, in a greased shallow baking pan. Let rise and bake.

Cloverleaf rolls.—Divide dough into very small pieces and roll into balls about ¾ inch in diameter. Dip each ball in melted butter or margarine and place three balls together in a greased muffin tin. Let rise and bake.

Biscuits

12 biscuits

2 cups flour 1 tablespoon baking powder 1 teaspoon salt ■ cup shortening About ¾ cup milk

Mix dry ingredients thoroughly. Mix in fat only until mixture is crumbly.

Add most of the milk and stir to mix. Add more milk as needed to make a dough that is soft but not too sticky to knead. Knead dough gently on a lightly floured surface 10 to 12 times. Form into a ball.

Pat or roll dough to ½- to ¾-inch thickness. Cut with a floured biscuit cutter or cut into squares with a knife. Place on an ungreased baking sheet—1 inch apart for crusty biscuits; together for softer biscuits.

Bake at 450° F. (very hot oven) 12 to 15 minutes, or until golden brown.

Variations

Cheese biscuits.—Combine ¾ cup shredded sharp or extra sharp cheese with dry ingredients before adding fat.

Sweet biscuits or shortcake.—Combine 1 tablespoon sugar with dry ingredients. Use ¼ cup butter or margarine for fat. Reduce milk to ■ cup. Bake at 425° F. (hot oven) 10 to 15 minutes.

Popovers

12 popovers

3 eggs 1 cup milk 2 tablespoons melted fat or oil 1 cup flour ½ teaspoon salt

Grease muffin tins and place them in an oven that is preheating at 450° F. (very hot).

Beat eggs well in a large mixing bowl. Add milk and fat. Mix flour and salt; add to liquid mixture. Beat until smooth.

Fill hot muffin tins half full of batter. Bake at 450° F. 15 minutes; reduce heat to 375° F. (moderate oven) and bake 10 minutes longer. Do not open oven door during baking.

Immediately after baking, insert a paring knife through the top of each popover to allow steam to escape.

Cornbread

6 servings

1 cup yellow cornmeal 1 cup flour 4 teaspoons baking powder ¼ or ■ cup sugar, as desired ½ teaspoon salt 1 cup milk 1 egg, beaten ¼ cup melted shortening or oil

Mix dry ingredients thoroughly. Combine milk and egg; stir in fat. Add liquid to dry ingredients; stir only enough to mix.

Pour batter into a greased 8- by 8- by 2-inch baking pan. Bake at 400° F. (hot oven) about 25 minutes, or until lightly browned.

Variation

Corn muffins.—Fill greased muffin tins half full of batter. Bake at 400° F. (hot oven) about 20 minutes. Makes 12 muffins.

Spoonbread

6 servings

3 cups milk 1 cup cornmeal 1½ teaspoons salt 2 tablespoons butter or margarine 4 egg yolks, beaten 4 egg whites

Combine milk, cornmeal, and salt. Cook over low heat, stirring constantly, until thickened, about 15 minutes. Mix in fat. Cool to lukewarm. Stir in egg yolks.

Beat egg whites until stiff, but not dry. Fold into mixture; pour into greased 1½-quart casserole.

Bake at 400° F. (hot oven) for 35 to 40 minutes or until set. Serve immediately.

Muffins

12 muffins

1 egg 1 cup milk ■ cup oil or melted shortening 2 cups flour 1 tablespoon baking powder 1 teaspoon salt ■ cup sugar

Beat egg until yolk and white are well blended. Blend in milk and fat.

Mix dry ingredients thoroughly. Add liquid and stir until dry ingredients are barely moistened. Do not overmix. Batter should be lumpy.

Fill greased muffin tins half full of batter. Bake at 400° F. (hot oven) 20 to 25 minutes.

Variations

Blueberry muffins.—Increase sugar to ½ cup. Lightly blend in ¾ cup fresh or drained canned blueberries when combining liquid and dry ingredients. Do not crush berries.

Bran muffins.—Reduce flour to 1¼ cups. Mix 2 cups bran flakes or raisin bran cereal with dry ingredients before adding liquid.

Oatmeal-raisin muffins.—Reduce flour to 1¼ cups. Mix 1 cup quick-cooking rolled oats and ½ cup raisins with dry ingredients before adding liquid.

Nut bread

1 loaf

■ cup sugar ¼ cup shortening 2 eggs 2 cups flour 3 teaspoons baking powder ½ teaspoon salt 1 cup orange juice or milk ½ teaspoon vanilla ■ cup chopped nuts

Beat sugar, shortening, and eggs until creamy.

Mix flour, baking powder, and salt thoroughly. Stir into egg mixture alternately with liquid and vanilla; stir nuts into last portion of flour mixture before blending it into batter.

Pour into greased 9- by 5- by 3-inch loafpan. Bake at 350° F. (moderate oven) 50 to 60 minutes, or until no batter clings to toothpick inserted in center of loaf. Remove from pan and cool on rack.

Quick coffee cake

6 servings

3 tablespoons softened butter or margarine ½ cup granulated sugar 1 egg 1 cup flour 1¼ teaspoons baking powder ¼ teaspoon salt ■ cup milk ¼ teaspoon vanilla ■ cup brown sugar, packed ½ teaspoon cinnamon 2 tablespoons butter or margarine

Mix 3 tablespoons fat with granulated sugar. Add egg and beat until creamy.

Mix flour, baking powder, and salt thoroughly; add to sugar mixture alternately with milk. Add vanilla. Spread batter evenly in a greased 8-inch square baking pan.

Mix brown sugar and cinnamon and sprinkle over batter. Dot with 2 tablespoons fat. Bake at 350° F. (moderate oven) 25 to 30 minutes.

Pancakes

About 12 pancakes, 4½ inches in diameter

2 cups flour 4 teaspoons baking powder 1 teaspoon salt 2 tablespoons sugar 1 egg, well beaten 1¾ cups milk ■ cup oil or melted fat

Heat griddle while mixing batter. When griddle is hot enough, drops of water sprinkled on it will bounce.

Mix dry ingredients thoroughly. Combine egg with milk and fat. Add to dry ingredients and stir only until combined. Batter will be lumpy.

For each pancake, pour about ¼ cup batter onto hot griddle. Cook until edges become slightly dry and bubbles form on top. Turn and brown the other side.

Variation

Waffles.—Increase eggs to 3. Pour batter into hot waffle iron and bake until steaming has almost stopped.

NOTE: For a lighter-textured waffle, beat egg whites separately until stiff but not dry. Fold into waffle batter.

Sandwiches

Sandwiches play many roles in family fare. You can make them fancy for teas and parties—light for snacks—or hearty for the main course at lunch or supper.

Spread sandwich fillings generously, all the way to the edge of the bread. Fillings should be moist, but not wet. Experiment with new fillings, and with different kinds of bread.

Bacon-cheese sandwiches

6 servings

6 slices bacon 6 slices bread 6 slices (1 ounce each) cheese

Cut bacon slices into halves crosswise; fry until most of fat has cooked out.

Preheat oven with broiler pan and rack in place.

Put a slice of cheese on each bread slice. Top with partly cooked bacon.

Place sandwiches under broiler to lightly brown bacon and melt cheese.

Barbecued beef sandwiches

6 servings

1½ pounds ground beef 1 cup chopped onion 1 cup chopped celery 1 can (8 ounces) spanish-style tomato sauce ¼ cup catsup 2 tablespoons brown sugar, packed 2 tablespoons vinegar 2 tablespoons barbecue sauce 1 tablespoon worcestershire sauce 1 tablespoon prepared mustard 2 teaspoons salt Pepper, as desired 6 hamburger buns

Crumble beef into saucepan and brown lightly. Drain off excess fat. Mix in onion and celery. Combine tomato sauce, catsup, brown sugar, vinegar, barbecue sauce, and seasonings. Pour over meat, cover pan, and simmer barbecue 1½ to 2 hours, or until flavors are well blended.

Spoon beef mixture over buns.

Fish-cheeseburgers

6 servings

6 frozen fried fish portions or 12 frozen fried fish sticks 6 buttered hamburger buns 6 tablespoons chili sauce 6 slices (1 ounce each) cheese

Place frozen fried fish portions or fish sticks in a single layer on a well-greased baking sheet. Bake at 400° F. (hot oven) 15 to 20 minutes, or until heated through.

Place 1 fish portion or 2 fish sticks on bottom half of each bun on a baking sheet. Top each sandwich with 1 tablespoon chili sauce, a slice of cheese, and other half of bun.

Bake at 350° F. (moderate oven) 8 to 10 minutes, or until cheese melts.

Meat salad sandwiches

6 servings

2 cups ground cooked meat ■ cup mayonnaise or salad dressing ■ cup pickle relish ½ teaspoon salt (omit when ham is used) Pepper, as desired 12 slices bread Softened butter or margarine

Combine meat, salad dressing, relish, and seasonings; mix well. Chill.

Spread bread with butter or margarine. Then spread 6 slices with meat mixture and top each with second slice of bread.

Variations

Grilled open-face sandwiches.—Use 6 slices bread. Toast bread on one side under broiler. Spread untoasted side of the bread with butter or margarine and meat mixture. Broil sandwiches until meat browns slightly. Serve piping hot.

Poultry salad sandwiches.—Use 2 cups of ground cooked poultry as the meat.

Desserts

Dessert adds a touch that gives a good dinner its final, satisfying note.

Before using the dessert recipes in this bulletin, refer to the section on ingredients and measurements (p. 16).

Cake recipes in this publication generally need to be adapted for use in high-altitude areas. Write to your State Experiment Station or contact your county extension agent for information on baking cakes in your area.

For pies and cakes, use pans of the size specified.

To grease pans for cakes, coat lightly with unsalted fat or oil. Then sprinkle lightly with a little flour. Tip pan from side to side to coat evenly; then shake out excess flour.

In recipes that call for greased and floured cakepans, you may use a wax paper lining if you prefer. Cut wax paper to fit the bottom of the pan. Then grease the paper lightly.

Pastry

8- or 9-inch pastry shell

1 cup flour ½ teaspoon salt ■ cup shortening About 2 tablespoons cold water

Mix flour and salt thoroughly. Mix in fat only until mixture is crumbly.

Add a little water at a time, blending lightly. Dough should be just moist enough to cling together when pressed.

Shape dough into a ball. Roll out on a lightly floured surface or between two sheets of waxed paper. Fit carefully into piepan. Lift edges and smooth out air bubbles. For baked pastry shell, trim pastry, leaving about 1 inch around the edge. Fold edge under and shape into an upright rim.

Prick bottom and sides well with a fork. Bake at 450° F. (very hot oven) 12 to 15 minutes, or until golden brown.

Variation

Two-crust pie.—Double the recipe. Form dough into two balls, one slightly larger than the other. Roll out larger ball of dough and fit into piepan. Roll out remaining dough for top crust; make several slits in crust to let steam escape during baking. Put filling into pastry-lined pan. Top with second crust. Fold edges of crusts under and press together to seal. Bake as directed in pie recipe.

Apple pie

8-inch pie, 6 servings

Pastry for 2-crust 8-inch pie (above) 5 cups pared, sliced tart apples ■ cup sugar 1 tablespoon cornstarch ½ teaspoon cinnamon 1 or 2 tablespoons butter or margarine, if desired

Prepare unbaked pastry.

Mix dry ingredients lightly with apples in a bowl. Put filling into pastry-lined pan. Dot with fat, if desired. Top with second crust.

Bake at 400° F. (hot oven) for 40 to 60 minutes, or until filling bubbles and the crust is golden brown.

NOTE: If fruit is sweet, decrease amount of sugar; if unusually tart, increase sugar.

Variations

Blueberry pie.—Use 3 cups fresh blueberries instead of apples. Omit cinnamon and increase cornstarch to 3 tablespoons. Sprinkle fruit with 2 tablespoons lemon juice. Bake 50 to 60 minutes.

Cherry pie.—Instead of apples, use 1 can (1 pound) pitted red sour cherries, water pack. Do not drain. Omit cinnamon. Increase cornstarch to 2 tablespoons. Add ■ teaspoon almond extract and a few drops of red food coloring, if desired. Bake 40 to 45 minutes.

Peach pie.—Use 3 cups fresh sliced peaches instead of apples. Use only ¼ teaspoon cinnamon. Bake 40 to 50 minutes.

Vanilla cream pie

8-inch pie, 6 servings

1 8-inch pastry shell (p. 64) 3 tablespoons cornstarch ¼ cup sugar ½ teaspoon salt 2 cups milk 2 egg yolks, beaten 2 tablespoons butter or margarine 1 teaspoon vanilla ½ cup whipping cream 1 tablespoon confectioner’s sugar

Prepare, bake, and cool pastry shell.

Mix cornstarch, sugar, and salt in heavy saucepan. Gradually stir in milk.

Cook over moderate heat, stirring constantly, until thickened. Simmer 1 minute longer.

Stir a little of the hot mixture into egg yolks; then stir yolks into remaining hot mixture. Cook 1 minute longer, stirring constantly. Stir in fat and vanilla.

Set saucepan in cold water to cool. Stir frequently. Change water occasionally.

Pour filling into pastry shell. Chill thoroughly.

Before serving, whip cream until stiff and beat in confectioner’s sugar. Spread over pie.

NOTES: _Use only clean, sound-shelled eggs in this recipe._

Use whipped dessert topping instead of whipped cream, if desired.

Variations

Coconut cream pie.—Stir ½ to 1 cup shredded coconut, as desired, into the hot filling with fat and vanilla.

Banana cream pie.—Slice 2 bananas into pie shell before adding filling.

Chocolate cream pie.—Increase sugar to ¾ cup. Cut 1½ ounces bitter chocolate into cream filling after adding milk.

Graham cracker crust

8- or 9-inch pie

■ cup butter or margarine 2 tablespoons sugar 1¼ cups graham cracker crumbs

Stir fat and sugar together in a saucepan over low heat until fat is melted. Blend in cracker crumbs. Press evenly into piepan. Chill.

Pecan pie

9-inch pie, 8 servings

1 unbaked 9-inch pastry shell (p. 64) 1 cup pecan halves 3 eggs, beaten ½ cup sugar 1 cup dark corn sirup ¼ teaspoon salt 1 teaspoon vanilla ¼ cup melted butter or margarine

Prepare unbaked pastry shell. Spread nuts in bottom of pastry shell.

Combine remaining ingredients and pour over nuts. Bake at 375° F. (moderate oven) 30 to 40 minutes, or until the filling appears set when the pie is gently moved.

Pumpkin pie

8-inch pie, 6 servings

1 unbaked 8-inch pastry shell (p. 64) 1 cup canned pumpkin ½ teaspoon cinnamon ¼ teaspoon ginger ¼ teaspoon nutmeg ■ teaspoon cloves 1 cup milk, half-and-half, or evaporated milk ½ cup sugar 1 egg, slightly beaten ½ teaspoon salt

Prepare unbaked pastry shell.

Blend pumpkin and spices thoroughly. Stir in remaining ingredients; mix well. Pour into pastry shell.

Bake at 400° F. (hot oven) about 1 hour. Pie is done when a table knife inserted in center comes out clean. Filling may be soft but will set on cooling.

Quick meringue-topped pie

8-inch pie, 6 servings

1 baked 8-inch pastry shell (p. 64) 1 package (3 to 4 ounces) pudding and pie filling mix, any flavor 2 egg whites ¼ teaspoon salt ¼ cup sugar

Prepare pastry shell.

Make pie filling according to package directions. Cool filling slightly; then pour into baked pastry shell.

Beat egg whites until foamy. Add salt and beat until soft peaks form. Add sugar gradually, beating constantly, and continue beating until stiff peaks form.

Pile meringue on pie while filling is still warm. Bake at 350° F. (moderate oven) 15 to 20 minutes, or until lightly browned.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Lemon chiffon pie

8-inch pie, 6 servings

1 8-inch graham cracker crust (p. 65) or baked pastry shell (p. 64) 1 tablespoon unflavored gelatin ¼ cup cold water 3 egg yolks ½ cup lemon juice ½ teaspoon grated lemon rind ¾ cup sugar 3 egg whites ¼ teaspoon salt

Prepare graham cracker crust or pastry shell.

Soften gelatin in cold water. Beat egg yolks slightly. Add juice, rind, and half the sugar. Cook over low heat, stirring constantly, until mixture begins to thicken, 10 to 15 minutes.

Add gelatin; stir until dissolved. Chill until mixture begins to thicken.

Beat egg whites until foamy. Add salt and beat until soft peaks form. Slowly add remaining sugar, beating constantly until stiff. Fold into chilled mixture.

Pour into crust and chill until firm.

NOTE: _Use only clean, sound-shelled eggs in this recipe._

Variation

Lime chiffon pie.—Use ½ cup lime juice and ½ teaspoon grated lime rind in place of lemon. Add a few drops of green food coloring to dissolved gelatin before chilling.

Fruit delight pie

9-inch pie, 8 servings

1 9-inch graham cracker crust (p. 65) 1 envelope whipped dessert topping mix 1 package (8 ounces) cream cheese, at room temperature ¼ cup confectioner's sugar ¼ teaspoon vanilla ½ cup chopped pecans 1 cup canned blueberry, peach, or cherry pie filling

Make graham cracker crust.

Prepare whipped dessert topping according to package directions. Beat in cream cheese, sugar, and vanilla until smooth. Stir in nuts.

Pour into pie shell. Top with pie filling. Chill at least 3 hours before serving.

Spiced prune cake

Two 8- or 9-inch layers

1 package spice cake mix (for 2-layer cake) 1¼ cups drained, pitted, and chopped cooked prunes

Prepare cake batter according to package directions. Thoroughly mix prunes into cake batter. Pour batter into two greased and floured 8- or 9-inch layer cakepans.

Bake according to package directions but increase baking time by 10 minutes. Cool cake a few minutes before removing from the pans. When cool, frost with creamy white frosting (p. 69).

Velvety white cake

Two 8-inch layers

2 cups cake flour 1¼ cups sugar 1 tablespoon baking powder 1 teaspoon salt ½ cup softened butter or margarine or shortening 1 cup milk 4 egg whites, unbeaten 1 teaspoon vanilla ¼ teaspoon almond extract, if desired

Mix dry ingredients well. Add fat and half of the milk; beat until creamy. Add remaining milk, egg whites, and flavoring; beat until creamy.

Pour into two 8-inch greased and floured layer cakepans. Bake at 375° F. (moderate oven) 25 to 30 minutes, or until the cake surface springs back when touched lightly. Cool cake for a few minutes before removing from the pans. When cool, frost as desired.

Gingerbread

6 to 9 servings

½ cup shortening ½ cup brown sugar, packed 1 egg ½ cup molasses 1½ cups flour ½ teaspoon salt ¾ teaspoon baking soda ½ teaspoon ginger ½ teaspoon cinnamon ½ cup boiling water

Beat shortening and sugar until creamy. Add egg and molasses; beat well.

Mix dry ingredients thoroughly. Add to molasses mixture alternately with boiling water. Beat after each addition.

Pour batter into a greased 8- by 8- by 2-inch baking pan. Bake at 350° F. (moderate oven) 35 to 40 minutes. Serve warm.

Upside-down cake

6 servings

2 tablespoons butter or margarine ½ cup brown sugar, packed 6 drained canned peach halves 6 drained maraschino cherries, halved 12 pecan halves 1 recipe quick coffee cake batter (p. 62)

Melt fat in a 9-inch layer cakepan over low heat. Sprinkle brown sugar over fat. Arrange fruit and nuts in sugar mixture.

Prepare coffee cake batter and pour over fruit; spread evenly. Bake at 350° F. (moderate oven) 30 to 40 minutes.

Loosen cake from sides of pan and invert on serving plate. Allow to cool 5 minutes before removing pan.

Variations

Use 12 canned apricot halves or 6 canned pineapple slices or 1 cup of drained canned crushed pineapple for the fruit.

Timesaver

Instead of quick coffee cake batter, use a 1-layer package of cake mix, prepared by package directions.

Cherry cobbler

6 servings

½ recipe sweet biscuit dough (p. 60) ■ cup sugar 2 tablespoons cornstarch 1 can (1 pound) pitted red sour cherries, water pack ■ teaspoon almond extract Few drops red food coloring 1 tablespoon butter or margarine

Make biscuit dough but do not roll out.

Blend sugar and cornstarch in a 1-quart saucepan. Gradually stir in cherries. Cook over moderate heat until thickened and clear, stirring constantly. Remove from heat. Add flavoring, food coloring, and fat. Pour into a 1½-quart casserole.

Drop biscuit dough by spoonfuls onto hot cherry mixture. Bake at 425° F. (hot oven) 15 to 20 minutes, or until filling bubbles and topping is lightly browned.

Timesaver

Quick cherry cobbler.—Use 1 can (1 pound 5 ounces) cherry pie filling. Heat to boiling and stir in 1 tablespoon butter or margarine. For biscuit topping, combine 1 cup packaged biscuit mix and 1 tablespoon sugar. Add ■ cup milk and 1 tablespoon melted butter or margarine; stir until moistened. Drop by spoonfuls onto hot cherry filling and bake as directed.

Chocolate cake

Two 8-inch layers

1¾ cups cake flour 1■ cups sugar 1 teaspoon salt 1 teaspoon baking soda ½ cup softened butter or margarine 1 cup milk 1 teaspoon vanilla 2 eggs 2 or 3 ounces (2 or 3 squares) unsweetened chocolate, melted

Mix dry ingredients well. Add fat and half of the milk; beat until creamy. Mix in remaining milk, vanilla, and eggs. Add chocolate; beat until creamy.

Pour into two 8-inch greased and floured layer cake pans. Bake at 350° F. (moderate oven) 30 to 35 minutes, or until the cake surface springs back when touched lightly. Cool cake a few minutes before removing from the pans. When cool, frost with creamy chocolate frosting (this page).

NOTE: For a loaf cake, use a greased and floured 9- by 12-inch cakepan. Bake about 40 minutes.

Creamy white frosting

For 8-inch layer cake or 9- by 12-inch loaf cake

About 2½ cups confectioner’s sugar ■ cup softened butter or margarine 3 tablespoons milk 1 teaspoon vanilla

Beat about 2 cups of the sugar with all other ingredients until frosting is creamy and smooth. Beat in enough of the remaining sugar for a frosting that will spread evenly. Spread on cooled cake.

Variation

Creamy chocolate frosting.—Mix in 1 or 2 ounces (1 or 2 squares) of melted chocolate. Or increase milk to ¼ cup and use ■ cup cocoa. Beat until creamy and smooth.

Caramel-nut frosting

For 8-inch layer cake or 9- by 12-inch loaf cake

½ cup butter or margarine 1 cup brown sugar, packed ¼ cup milk 2 cups confectioner's sugar ■ cup finely chopped pecans or walnuts ½ teaspoon vanilla Nut halves, as desired

Combine, fat, brown sugar, and milk. Cook over medium heat, stirring constantly, only until mixture boils and sugar is dissolved. Cool slightly.

Beat confectioner's sugar into cooked mixture until frosting reaches spreading consistency. Add chopped nuts and vanilla; mix well.

Spread on cooled cake. Garnish with nut halves.

Orange bavarian cream

6 servings

1 tablespoon unflavored gelatin ¼ cup cold water ¾ cup orange juice 2 tablespoons lemon juice ½ teaspoon grated orange rind ■ cup sugar ¼ teaspoon salt 1 cup whipping cream 1 cup fresh orange sections, cut in pieces

Soften gelatin in water. Combine fruit juices, orange rind, sugar, and salt; heat to simmering. Dissolve gelatin in hot mixture. Chill until mixture begins to thicken.

Whip cream only until stiff. Fold whipped cream and orange sections into gelatin mixture. Pour into a 1-quart mold and chill until firm.

Oatmeal cookies

3 to 4 dozen cookies

1 cup flour 1¼ teaspoons baking powder ½ teaspoon baking soda ½ teaspoon salt ½ cup shortening 1 cup brown sugar, packed 1 egg ¾ teaspoon vanilla 1½ cups quick-cooking rolled oats

Mix flour, baking powder, soda, and salt. Beat shortening and sugar until creamy. Beat in egg and vanilla. Blend in flour mixture. Stir in rolled oats. Chill.

Shape dough into balls about 1 inch in diameter. Place about 2 inches apart on an ungreased baking sheet. Bake at 350° F. (moderate oven) 10 to 15 minutes.

Remove from baking sheet while warm.

Variations

Raisin-oatmeal cookies.—Add ½ cup raisins with the oats.

Coconut- or nut-oatmeal cookies.—Add ½ cup flaked coconut or ½ cup chopped nuts with the oats.

Orange-oatmeal cookies.—Add 2 tablespoons orange juice and 1 teaspoon grated orange rind to shortening and sugar mixture. Add ½ cup raisins and ½ cup chopped nuts with the oats. Chill dough thoroughly; drop from teaspoon onto baking sheet.

Peanut butter cookies

4 to 5 dozen cookies

1 cup shortening 1 cup peanut butter 1 cup granulated sugar 1 cup brown sugar, packed 2 eggs 1 teaspoon vanilla 2½ cups flour ½ teaspoon salt ¾ teaspoon baking soda ½ teaspoon baking powder

Beat shortening and peanut butter until creamy. Gradually add sugars, beating thoroughly after each addition. Beat in eggs and vanilla.

Mix remaining ingredients and blend into peanut butter mixture. Shape dough into balls about 1 inch in diameter. Place about 2 inches apart on an ungreased baking sheet. Flatten each cookie. Criss-cross top of each cookie with a fork, if desired.

Bake at 375° F. (moderate oven) 10 to 15 minutes.

Remove from baking sheet while warm.

Variation

Top-hat cookies.—Roll balls of dough in granulated sugar before placing on baking sheet. Do not flatten. Bake 10 minutes; then remove from oven and press a milk chocolate candy kiss into center of each cookie. Return to oven and bake 2 to 5 minutes longer, or until cookies are done.

Molasses snaps

3 to 4 dozen cookies

¾ cup shortening 1 cup brown sugar, packed 2 eggs ¼ cup molasses 2¼ cups flour 2 teaspoons baking soda ½ teaspoon salt ½ teaspoon cloves 1 teaspoon cinnamon 1 teaspoon ginger ½ cup chopped nuts, if desired ½ cup raisins, if desired

Beat shortening and sugar until creamy. Beat in eggs and molasses.

Mix dry ingredients and stir in raisins and nuts, if used. Stir flour mixture into molasses mixture.

Drop dough from a teaspoon onto a lightly greased baking sheet; space cookies about 2 inches apart. Bake at 375° F. (moderate oven) 10 to 12 minutes, or until set but not hard.

Remove from baking sheet while warm.

Chocolate sparkles

5 to 6 dozen cookies

1 cup softened butter or margarine 1¼ cups sugar 2 eggs 2 ounces (2 squares) unsweetened chocolate, melted ½ teaspoon vanilla 2■ cups flour 2 teaspoons cream of tartar 1 teaspoon baking soda ½ teaspoon salt ¼ cup sugar

Beat fat and 1¼ cups sugar until creamy. Beat in eggs; add melted chocolate and vanilla.

Mix flour, cream of tartar, soda, and salt. Stir into chocolate mixture; blend well. Chill dough.

Shape dough into balls about 1 inch in diameter. Roll balls in ¼ cup sugar and place about 2 inches apart on an ungreased baking sheet. Bake at 400° F. (hot oven) 8 to 10 minutes.

Remove from baking sheet while warm.

Variations

Cinnamon-sugar cookies.—Omit chocolate. Roll balls of dough in a mixture of ¼ cup sugar and 1 tablespoon cinnamon; bake as directed.

Chocolate chip cookies.—In place of 1½ cups granulated sugar, use ½ cup granulated sugar and 1 cup brown sugar. Beat sugars with butter or margarine. Omit the chocolate. Stir ■ cup chopped nuts and 1 package (12 ounces) chocolate chips into the dough. Drop dough from a teaspoon onto an ungreased baking sheet and bake as directed.

Apple crisp

6 servings

2 tablespoons granulated sugar ¼ teaspoon cinnamon 4 cups pared, sliced tart apples ¼ cup water ½ cup flour ■ teaspoon salt ¼ teaspoon cinnamon ¼ teaspoon nutmeg ■ cup brown sugar, packed 3 tablespoons softened butter or margarine

Mix granulated sugar with ¼ teaspoon cinnamon; sprinkle over apples and mix lightly. Spread apples in a greased 8- by 8- by 2-inch baking pan. Sprinkle with the water.

Blend flour, salt, cinnamon, nutmeg, and brown sugar. Mix in fat to make a crumbly mixture. Spread over apples. Bake uncovered at 350° F. (moderate oven) 40 minutes or until lightly browned and apples are tender.

Baked apples

6 servings

6 large baking apples 6 tablespoons sugar 2 tablespoons butter or margarine Cinnamon, as desired ½ cup water

Wash and core apples. Pare apples one-third of the way down or slit the skin around the apple about half-way down.

Place apples in a baking dish. Put sugar and butter or margarine in the center of each apple. Sprinkle with cinnamon. Pour the water around apples to prevent sticking.

Bake uncovered at 400° F. (hot oven) until tender, 45 minutes to 1 hour.

Variation

Cranberry-baked apples.—Omit the sugar, fat, and cinnamon. Combine ¾ cup chopped raw cranberries, ½ cup sugar, and 3 tablespoons chopped nuts. Stuff apples with this mixture before baking.

Brownies

16 brownies

2 ounces (2 squares) unsweetened chocolate ■ cup shortening or oil 1 cup sugar 2 eggs, slightly beaten 1 teaspoon vanilla ■ cup flour ½ teaspoon baking powder ½ teaspoon salt ½ cup chopped nuts

Melt chocolate and fat together over low heat. Cool slightly. Mix sugar with eggs.

Stir chocolate mixture into eggs gradually. Add vanilla.

Mix dry ingredients, stir in nuts, and add to chocolate mixture.

Spread batter in a greased 8-inch square baking pan. Bake at 350° F. (moderate oven) 25 to 30 minutes or until crust is shiny and brownies begin to shrink from pan. Cool in pan. Cut into 2-inch squares.

Variation

Chewy brownies.—Follow directions above, but omit baking powder.

Baked custard

6 servings

4 eggs, slightly beaten ■ cup sugar ¼ teaspoon salt 3 cups hot milk 1 teaspoon vanilla Nutmeg, as desired

Combine eggs, sugar, and salt. Stir in the milk gradually. Add vanilla.

Pour into custard cups. Sprinkle with nutmeg. Set cups in a pan of hot water.

Bake at 325° F. (slow oven) 30 to 40 minutes, or until the tip of a knife inserted in the center comes out clean.

Raisin-nut bread pudding

6 servings

2 cups milk 1 tablespoon butter or margarine ¼ cup brown sugar, packed 1 teaspoon cinnamon ½ teaspoon nutmeg ½ teaspoon vanilla 2 egg yolks, slightly beaten 4 slices bread, cut in 1-inch cubes ½ cup raisins ½ cup slivered almonds 2 egg whites ¼ teaspoon salt

Heat milk. Stir in fat, sugar, cinnamon, nutmeg, and vanilla.

Stir a little of the milk mixture into egg yolks; then stir yolks into rest of milk mixture. Add bread cubes, raisins, and half the nuts.

Beat egg whites until foamy. Add salt and beat until stiff but not dry. Fold egg whites into pudding mixture. Pour into greased 1-quart casserole. Sprinkle top with rest of nuts. Place casserole in pan of hot water.

Bake at 325° F. (slow oven) 1¼ to 1½ hours, or until the tip of a knife inserted in the center comes out clean.

Quick ice cream desserts

Pecan balls.—Toast pecans by spreading 1½ cups in a shallow pan, and baking at 300° F. (slow oven) 15 to 20 minutes, or until lightly browned. Cool and chop. Shape 1 quart ice cream into 6 balls. Roll balls in pecans. Place on a tray covered with wax paper and return to freezer until firm. Just before serving, top balls with hot fudge sauce. Makes 6 servings.

Snowballs.—Shape 1 quart ice cream into 6 balls. Roll balls in ½ cup flaked coconut. Return balls to freezer as directed above. Makes 6 servings.

Ice cream sandwiches.—Slice 1 quart ice cream into 6 slices. Place each slice between 2 graham crackers (plain, cinnamon-flavored, or chocolate-coated). Serve immediately or return to freezer until time to serve. Makes 6 sandwiches.

Buttered nut sundae.—Add ½ cup chopped pecans or walnuts to 2 tablespoons melted butter or margarine in a frypan. Toast nuts over low heat for 15 to 20 minutes, stirring as needed, until they are lightly browned. Stir in ¼ cup brown sugar (packed) and ¼ cup water; simmer 2 minutes. Pour warm sauce over ice cream. Makes about ¾ cup or enough for 6 sundaes.

Ways to Use Leftovers

Don’t throw good leftover food away. Use your cooking skill—and your imagination—to make leftovers tasty.

Some leftovers make good second meals merely by reheating. Others are better prepared in a new way—with seasonings, sauces, crisp toppings. Try leftover fruit in muffins, vegetables in omelets. Substitute 2 leftover egg yolks for 1 whole egg in baked custard. And soups often become richer, more delicious when leftovers are added.

Listed below are some of the ways in which leftovers may be used.

Cooking Terms

=Bake= To cook in an oven or oven-type appliance in a covered or uncovered container.

=Barbecue= To roast slowly on a spit or rack, usually basting with a highly seasoned sauce. Also, foods cooked in or served with barbecue sauce.

=Baste= To pour melted fat, drippings, or other liquid over food to moisten it during cooking.

=Boil= To cook in water or other liquid at boiling temperature (212° F. at sea level). Bubbles rise continually and break on the surface.

=Braise= To cook meat or poultry slowly in steam from meat juices or added liquid trapped and held in a covered pan. Meat may be browned in a small amount of fat before braising.

=Broil= To cook uncovered on a rack placed directly under heat or over an open fire. _Pan broil._—To cook in uncovered pan over direct heat, pouring fat off as it accumulates.

=Caramelize= To heat sugar or food containing sugar until a brown color and characteristic flavor develop.

=Fold= To combine two mixtures (or two ingredients such as beaten egg white and sugar) by gently cutting down through mixture, turning over, and repeating until well mixed.

=Fry= To cook in fat without water, uncovered. _Pan-fry or saute._—To cook in frypan in a small amount of fat. _Deep-fry or french-fry._—To cook in a deep kettle, in enough fat to cover or float food.

=Grill= Same as broil.

=Knead= To press, stretch, and fold dough or other mixture to make it elastic or smooth. Bread dough becomes elastic; fondant becomes smooth and satiny.

=Marinate= To let foods stand in a liquid (usually mixture of oil with vinegar or lemon juice) to add flavor or to make more tender.

=Parboil= To boil until partly cooked.

=Poach= To simmer gently in liquid so food retains its shape.

=Pot-roast= To cook large cuts of meat by braising.

=Reconstitute= To restore concentrated food—such as frozen orange juice or dry milk—to its original state, usually by adding water.

=Rehydrate= To soak or cook dried foods to restore the water lost in drying.

=Roast= To cook in heated air—usually in an oven—without water, uncovered.

=Simmer= To cook in liquid just below the boiling point, at temperatures of 185° to 210° F. Bubbles form slowly and break below the surface.

=Steam= To cook food in steam, with or without pressure. Food is steamed in a covered container on a rack or in a perforated pan over boiling water.

=Stew= To cook in liquid, just below the boiling point.

Index to Recipes

Page

Apple(s): baked, 72 crisp, 72 pie, 64

Barbecued beef sandwiches, 63

Bean(s): Boston baked, 41 green: creole, 46 ham-seasoned, 47 mushroom casserole, 48 lima, creole, 46 salads, marinated, 50 soup, 55

Beef: braised, 21 broiled, 18 liver and onions, braised, 24 loaf, 25 pan-broiled, 20 pie, quick, 22 pot roast, 21 roast, 18 stew, 26 stroganoff, 22 (_See also_ Sandwiches.)

Beets, Harvard, 47

Biscuit(s): cheese, 60 plain, 60 sweet (shortcake), 60

Bread(s): coffee cake, quick, 62 cornbread, 60 croutons, 56 french toast, 37 nut bread, 61 pancakes, 62 popovers, 60 pudding, raisin-nut, 73 spoonbread, 61 waffles, 62 (_See also_ Biscuits, Muffins, Rolls, Sandwiches.)

Cabbage, hungarian, 45

Cake(s): chocolate, 69 coffee, quick, 62 frosting: caramel-nut, 69 chocolate, creamy, 69 white, creamy, 69 spiced prune, 67 upside-down, 68 velvety white, 67

Carrots, glazed, 47

Cauliflower au gratin, quick, 46

Cheese: baked fondue, 40 biscuits, 60 burgers, fish, 63 croutons, 56 pizza, 40 salad dressing, Roquefort (blue), 53 sauce with macaroni, 40 with spanish rice, 39

Cherry: cobbler, 68 cobbler, quick, 69 pie, 65

Chicken: a la king, 30 braised, with vegetables, 31 broiled, 29 fried, 29 noodle bake, 30 oven-fried, 29 pie, 31 roast, 27 stewed, 29 vegetable soup, 54 with homemade noodles, 32

Chowder. (_See_ Soup.)

Coleslaw, 52

Cookies: brownies, chewy, 72 brownies, plain, 72 chocolate chip, 71 chocolate sparkles, 71 cinnamon-sugar, 71 molasses snaps, 71 oatmeal: coconut or nut, 70 orange, 70 plain, 70 raisin, 70 peanut butter, 70 top hat, 71

Corn muffins, 61

Cornbread, 60

Cranberry-baked apples, 72

Croutons, 56

Custard, baked, 73

Desserts: apple crisp, 72 apples, baked, 72 bavarian cream, orange, 70 cobbler, cherry, 68 raisin-nut bread pudding, 73 (_See also_ Cakes, Cookies, Custard, Ice Cream Desserts, Pies.)

Duck, roast, 27

Eggplant: casserole, 47 creole, 46

Egg(s): baked in hash nests, 39 deviled: ham, 38 plain, 38 french toast, 37 fried, 37 in shell: hard-cooked, 37 soft-cooked, 37 omelet, plain (french), 38 poached, 38 poached, supreme, 38 sauce, 57 scrambled, 36

Fish: baked, 34 baked stuff, 35 broiled, 34 buying, 10 cheeseburgers, 63 chowder: Manhattan, 55 New England, 55 deep-fat fried, 32 oven-fried, 35 pan-fried, 32 salad, souffle, 51 salmon loaf, 34 sardine puff, 36 servings per pound, 7 storing, 14 topsy turvy tuna pie, 35

Frosting. (_See_ Cakes.)

Fruits. (_See_ Desserts, Pies.)

Goose, roast, 27

Graham cracker pie crust, 65

Gravy, 57

Ham: patties, 24 roast, 18 slice, broiled, 18 slice, pan-broiled, 20

Ice cream desserts: buttered nut sundae, 73 ice cream sandwiches, 73 pecan balls, 73 snowballs, 73

Lamb: braised, 21 chops, broiled, 18 chops, pan-broiled, 20 curried, 23 roast, 18 stew, irish, 26

Liver and onions, braised, 24

Luncheon meat: saucy, 25 special, 23

Macaroni with cheese sauce, 40

Meat: buying, 8 curried, 23 grades, 8 loaf 25 salad sandwiches, 63 salad, souffle, 51 servings per pound, 7 storing, 14 (_See also_ Beef, Lamb, Liver, Luncheon Meat, Pork, Sausage, Veal.)

Meringue-topped pie, quick, 66

Muffins: blueberry, 61 bran, 61 corn, 61 oatmeal-raisin, 61 plain, 61

Noodle(s): chicken bake, 30 homemade, with chicken, 32 turkey bake, 30

Oatmeal: cookies, 70 raisin muffins, 61

Okra and tomatoes, stewed, 45

Omelet, plain (french), 38

Onion(s): and liver, braised, 24 in mushroom sauce, 48 sauce, 57

Pancakes, 62

Pastry, for pies, 64

Pea salad, 53

Peanut butter cookies, 70

Peppers, green, stuffed, 25

Pie(s): apple, 64 blueberry, 65 cherry, 65 chicken, 31 cream: banana, 65 chocolate, 65 coconut, 65 vanilla, 65 fruit delight, 67 graham cracker crust, 65 lemon chiffon, 66 lime chiffon, 67 pastry, 64 peach, 65 pecan, 66 pumpkin, 66 quick meringue-topped, 66 turkey, 31

Pizza, 40

Popovers, 60

Pork: braised, 21 chops, broiled, 20 curried, 23 roast, 18 (_See also_ Ham.)

Potato(es): and sausage, au gratin, 23 baked stuffed, 48 patties, 48 salad, 52 soup, creamy, 56

Poultry: salad, sandwiches, 63 salad, souffle, 51 (_See also_ Chicken, Duck, Goose, Turkey.)

Prune: cake, spiced, 67 salad, stuffed, 52

Pudding, raisin-nut bread, 73

Rice, spanish with cheese, 39

Rolls, yeast: cinnamon-nut, 59 cloverleaf, 60 crescent, 59 plain, 59

Salad(s): chef salad bowl, luncheon, 52 coleslaw, 52 creamy fruit, 51 fish, souffle, 51 frozen fruit, 51 marinated vegetable, 50 asparagus spear, 50 cucumber and onion, 50 green bean, 50 three-bean, 50 meat, souffle, 51 pea, 53 pineapple-carrot, molded, 51 potato, 52 poultry, souffle, 51 prune, stuffed, 52 suggested combinations: fruit, 50 vegetable, 50

Salad dressing(s): blue cheese, 53 celery seed, 53 french: basic, 53 sweet, 53 orange-honey, 53 italian, 53 Roquefort cheese, 53 thousand island, 53

Sandwich(es): bacon-cheese, 62 barbecued beef, 63 fish-cheeseburgers, 63 grilled open-face, 63 meat salad, 63 poultry salad, 63

Sauces: cheese, 57 egg, 57 honey-orange, 58 lemon-butter, 58 mock hollandaise, 58 onion, 57 quick vegetable, 58 sour cream, 58 tartar, 58 white, 57

Sausage and potatoes au gratin, 23

Soup(s): bean, 55 broccoli, cream of, 56 chicken-vegetable, 54 fish chowder: Manhattan, 55 New England, 55 potato, creamy, 56 turkey-vegetable, 54 vegetable, hearty, 54

Spaghetti with meat sauce, 24

Spinach: au gratin, quick, 46 souffle, 44

Spoonbread, 61

Squash, zucchini, scalloped, 46

Steak(s): braised, 21 broiled, 18 pan-broiled, 20

Stew: beef, 26 irish, 26

Stuffing: nut, 28 plain, 28

Sweetpotatoes in orange shells, 45

Tomato(es): and okra, stewed, 45 broiled, 45

Turkey: boneless roast, 28 noodle bake, 30 pie, 31 roast, stuffed, 27 vegetable soup, 54

Veal: braised, 21 curried, 23 roast, 18

Vegetable(s): boiled, 42 chicken soup, 54 creamed, 43 mashed, 43 panned, 44 salad combinations, 50 salads, marinated, 50 sauce, quick, 58 soup, hearty, 54 turkey soup, 54 with a sauce, 44 with braised chicken, 31 (_See also_ other Vegetables, Salads, Sauces, Soups.)

FAMILY FARE is a result of USDA research. Here, the Agricultural Research Service brings together information on nutrition, food management, and food preparation.

Guidelines for nutritious meal planning and for food management came from the Consumer and Food Economics Research Division of ARS. Basic cooking methods and recipes were developed and taste-tested in the ARS Food Quality and Use Laboratory of the Human Nutrition Research Division. Fish recipes and information on buying fish were contributed by home economists in the Bureau of Commercial Fisheries, Department of the Interior.

This is a _Consumer Service_ of USDA

THE

VIRTUES

OF

COMMON WATER.

[Illustration]

For the benefit of mankind in general, I have taken pains to give the world an account of what I have found written in the works of the most eminent physicians, concerning the good that mankind may receive from the use of Common Water; and of the

informations I have had concerning the benefits thereof from others by word of mouth; and of what I have discovered by my own experience, from frequent trials, during a time that hath intervened from that of thirty to seventy-four years of age: which is sufficient to confirm the stupendious effects thereof; especially in the many particulars that shall be mentioned as my own discovery with respect to this excellent remedy, which will perform cures with very little trouble, and without any charge, and is also to be had wherever there are any habitations, which can hardly be said of any other: So that in some sense water may be truly stiled, _an universal remedy_, since the diseases it either prevents or cures may have this remedy applied to all persons, and in all places where men inhabit.

[Sidenote: _Excellency of Water._]

The first commendation of Common Water I shall mention, is that of Dr Manwaring, in his _Method and means of enjoying health_; wherein he saith, that water is a wholesome drink, or rather the most wholesome--being appointed for man in his best state; which doth strongly argue that drink to be the most suitable for human nature--answering all the intentions of common drinks; for it cools, moistens, and quencheth thirsts; 'tis clear, thin, and fit to convey the nourishment through the smallest vessels of the body--and it is a drink that is a rule to itself, and requires little caution in the use of it, since none will be tempted to drink of it more than needs: And that, in the primitive ages of the world, water-drinkers, he says, were the longest livers by some hundreds of years--not so often sick and complaining as we are.

[Sidenote: _Digestion to help._]

Dr Keill, treating of the stomach, in his _Abridgment of the anatomy of human bodies_, saith, that water seems the fittest to promote the digestion of food; all spirituous liquors having a property by which they hurt, rather than help digestion; the sad effects of which they are sensible of, he saith, who by a long use thereof have lost their appetites, hardly ever to be restored without drinking water, which seldom faileth of procuring a good appetite and a strong digestion. With which Dr. Baynard agrees, affirming, "That water liquifies and concocts our food better than any fermented liquor whatever." _Hist. of cold bathing_, p. 440.

[Sidenote: _Diseases to prevent._]

Dr. Prat, in his _treatise of mineral waters_, shews it to be his judgment, that, if people would accustom themselves to drink water, they would be more free from many diseases; such as tremblings, palsies, apoplexies, giddiness, pains in the head, gout, stone, dropsy, rheumatism, piles, and such like: which diseases are most common among them that drink strong drinks, and which water generally would prevent. Moreover, he saith, that water plentifully drank, strengthens the stomach, causeth an appetite, preserves the sight, maketh the senses lively, and cleanseth all the passages of the body, especially those of the kidneys and bladder.

[Sidenote: _Health to procure by Water._]

'Tis also said by Dr. Duncan, in his _treatise of hot liquors_, that, when men contented themselves with water, they had more health and strength; and that at this day those who drink nothing but water are more healthy, and live longer, than those who drink strong liquors, which raise the heat of the stomach to excess, whereas water keeps it in a due temper. And he adds in another part of the book, that by hot liquor the blood is inflamed; and such whose blood is inflamed, live not so long as those who are of a cooler temper; a hot blood being commonly the cause of fluxes, rheums, ill digestion, pains in the limbs, head-ach, dimness of sight, and especially of hysteric vapours. He also imputes the cause of ulcers to a hot blood, and declares, that if men kept their blood cool and sweet, by a moderate and cooling diet, they would never be troubled with ulcers, or other breakings-out. Which coolness of the blood will be well attained to by drinking a large draught of water in the morning, which also will carry off the bilious and salt recrements by urine. And, if water is drank also after dinner, it will cool a hot stomach, and prevent the rising of those fermentations which cause wind and belching after meat. So that if persons who are liable to these disorders will leave off strong liquors and a hot diet, and drink water, they will procure better health to themselves than they had before.

[Sidenote: _Some of the good properties of Water._]

Sir John Floyer also, in his _treatise of cold baths_, p. 109, edit. 5, affirms, that water-drinkers are temperate in their actions, prudent and ingenious; they live safe from those diseases which affect the head, such as apoplexies, palsies, pain, blindness, deafness, gout, convulsions, trembling, madness: And the drinking of water cures the hiccough, fætor of the mouth, and of the whole body; it resists putrefaction, and cools burning heats and thirsts, and after dinner it helps digestion.--And if the virtues of cold water were seriously considered, all persons would value it as a great medicine, in preventing the stone, asthma, and hysteric fits; and to the use of this, children ought to be bred up from their cradles. And, in page 434, he saith, That as water is in chief the

universal drink of the world--so it is the best, and most salubrious. And, in page 434. That he hath known where a regular drinking of spring-water hath done considerable cures by washing off the acrid, scorbutic salts from the blood, and strengthening the coats and fibres of the stomach and bowels, and hath brought on a good appetite, and a strong digestion. And I add, that it will infallibly do it in all curable cases.

[Sidenote: _Cold Water strengthening._]

Having read over an old book written by Sir Thomas Elliot, intituled, _The castle of health_, he there declared from his own experience, that in the county of Cornwall, tho' it was a very cold quarter, the poorer sort, which in his time did never, or but very seldom, drink any other drinks but water, were strong of body, and lived to a very great age. To which relation that of Sir Henry Blunt's is very agreeable, who affirmed, in his book of travels into the Levant, (where under the Turkish government the use of wine was forbid, and where the common drink is water) that he then had a better stomach to his food, and digested it more kindly than he ever did before or since.

[Sidenote: _Digestion considered._]

And in the _treatise of the vanity of philosophy_, written by Dr. Gideon Harvey, it is affirmed, that it is not heat that causeth a good digestion, but a proper ferment, or liquor provided by nature, to dissolve the food into a substance like unto pap made with fine flour; which dissolvent, he saith, is much depraved by hot spirituous liquors; and therefore he commends water above all other drinks to promote digestion.

[Sidenote: _Gout and Hypochondriac Melancholy._]

Water-drinking is also said by Dr. Allen to be good to prevent two deplorable distempers, the gout and the hypochondriac melancholy; For, says he, the gout is generally caused by too great drinking of fermented liquors, and is never said to have assaulted any drinker of water; and he saith also, that melancholy hypochondriac is kept off longest by drinking water instead of strong drink. To which let me add, that I once knew a gouty gentleman, who, to avoid his drinking companions in London, retired to New Brentford, where I then lived; in which town, by a very temperate diet of one meal a day, and drinking only water, he lived two whole years free from pain: But being visited by one who came that way, and invited to drink but one bottle of Claret between them, he fell next day into a terrible fit of the gout, which held above a month after; of which being recovered, he by the same course continued well till I left the place, which was about a year and an half after.

[Sidenote: _Gravel._]

The good properties of water are further manifested in preventing the breeding of gravel in the kidneys; for Zechias, in _Consult._ 17. as quoted by Salmon, affirms, that nothing so much abates the heat of the kidneys, and frees them from those recrements which cause pain in the back, one great sign of gravel, as water does; but he adviseth to drink it warm. By the use of which, he saith, the unnatural heat in time will be so extinguished, that no more of that matter causing gravel will be produced in the body. Which assertion by experience I have found to be true; for observing much gravel to be voided by me, also abundance of matter floating in the urine like bran; with a great number of recrements like cuttings of hair, some above an inch long, which substances were found in all the water that I made in above twelve months; for which I could get no remedy: I was advised to drink water, which in about half a year did entirely free me from those symptoms, which some out of ignorance imputed to witchcraft, so that from that time to this I never have been troubled with it.

[Sidenote: _Stone in the Bladder._]

Water also is commended as efficacious to prevent the breeding of the stone in the bladder; for it hath been observed, that in some who have been cut for the stone, that new stones have been engendered, so that some young persons have been cut several times. Now, to prevent this, the drinking water hath been advised with success; for by this that intemperate heat in the body was abated, which did occasion the distemper. Some have advised to drink it warm, and others cold, particularly Van Heyden, a physician of Ghent in Flanders, in his book intituled, _Help for the rich and poor_; which, he saith, in p. 40, is sufficiently insinuated by Piso and Alexander, who assure us, that the taking a draught of cold water in the morning hath done so much good, that several, after the voiding of a stone, never had any more stones grew in them.

[Sidenote: _Stone to dissolve._]

Which experiment may give light to the discovery of a way to cure the stone without cutting: For if the growing of new stones can be prevented by drinking water, let it be hot or cold, it may prevent a stone from growing bigger when begun; and if the adding matter to increase a stone new begun, can be prevented, nature in time may waste that which is begun, especially if some drops of sweet spirit of nitre be added to all the water drank, which will powerfully help to cool, and is known to be an admirable mover or provoker of urine, and will waste a stone, and make it crumble like fuller's earth, if applied to a stone taken from the body. Or the water may be sweetened with honey, which is now much in use among the gentry, as I am informed by an ingenious apothecary; who told me, that, among them at present, pump-water and honey are in great repute to give ease in gravel: And there is so near an affinity between gravel and the stone, that what is proper for one, will doubtless be suitable for the other, and will prevent the growth of both.

[Sidenote: _Beneficial in child-bearing._]

Water is also stiled in Senertus' works, _The balsam of children_, the drinking of it by the mother being one of those things whereby children will be strengthened in the womb, and will prevent those injuries that are done them by womens drinking strong liquors; which Samson's mother was not allowed to do, for she was commanded not to drink wine or strong drink, Judg. xiii. 4. But I will not say, if all women should do this, their children shall be as strong as Samson was; yet this I will say, if they would do this, they would find their children more free from distempers and frowardness, and so much more easy to nurse and bring up, and be less liable to an immature death; the want of which abstinence from strong drinks, is the cause why so many rich people find it hard to bring up children, in comparison to what is done by the poor: For these last are born of mothers who not only are prevented from being gluttons by their want of dainties, which are deceitful meat, Prov. xxiii. 3. but they seldom taste wine or strong drink; whereas the rich not only feed high, but also drink strong drinks, which in most constitutions do overheat and corrupt the humours of the body, and that blood by which their children are nourished during their pregnancy: which injury to unborn infants would be prevented, if the mother would be temperate in diet, and drink water, especially at meals, by which the blood of the mother would be kept cool and clean; which must needs communicate a healthful substance to the child within her, and prevent all those distempers which infants bring with them into the world.

[Sidenote: _Increases milk in women._]

And here it may be proper to add, what by divers experiments it hath been found to be true, that the drinking water by nurses, while they give suck to children, will wonderfully increase milk in those that want it, as every one will find, who can be persuaded to make use thereof. I have advised many to use it, who have found that, by drinking a large draught of water at bed-time, they have been supplied with milk sufficient for that night; when before they wanted it, and could not be supplied by any other means: And besides, they who have found their children restless, by reason of too much heat in their milk, do find them much more quiet after their milk is cooled by water-drinking.

[Sidenote: _Stays hunger, and prevents starving._]

By drinking water also the want of food for a time may be suffered without starving: For I have been informed by a credible friend, who was an officer at sea, that being sent down to Stafford to see some men conveyed on shipboard, that had been pressed by act of Parliament for the sea-service; he found in the prison where they were kept a lusty fellow, who had declared he would starve himself rather than go to sea; and, taking particular notice thereof, he found upon due enquiry, that for twenty days he had refused to eat any manner of food, only he drank each day about three pints or two quarts of water, hoping thereby to get himself discharged: But when he found his pretensions to be in vain, and that in or about two days they should all march for London, he condescended to eat some food, beginning with a little; and in the march he was observed to travel as well as the best man. I find also an account in Dr. Car's letters, of a certain crack-brained person, who at Leyden, when the doctor resided in that university, pretended he could fast as long as Christ did; and it was found he held out the time of forty days without eating any food, only he drank water and smoked tobacco. And I once had a sad complaint from a poor old woman of the greatness of her want, affirming, that oftentimes she had not eaten any food for two or three days; upon which I asked her, if she did not then suffer much uneasiness in her stomach? she said she did; but found a way at last to asswage her hunger by drinking water, which satisfied her appetite.

[Sidenote: _Strengthens weak children._]

Water is also of great use to strengthen weak children; For we are informed by Dr Joseph Brown, in his _treatise of cures performed by cold baths_, that the Welsh women do preserve their children from the rickets, by washing them night and morning in

cold water, till they are three quarters of a year old, p. 79. And 'tis said by Sir John Floyer, in his _treatise on cold baths_, that a lady in Scotland, who had lost several children thro' weakness, did, by the advice of a Highland beggar woman, preserve those she had afterwards, by washing them daily in cold water. And I myself advised a neighbour, whose child began to be ricketty, to treat the child in the same manner; but she, instead of washing, dipped it over head and ears every morning, it being then in the summer-time: The event of which was, the child became strong, and had a good countenance, tho' before it was very pale and wan: Which shews how great the power of water is, when used outwardly, to invigorate the spirits, and strengthen nature.

[Sidenote: _Swellings from bruises._]

It is also a known custom, to prevent the swellings that follow bruises in the faces of children, by immediately applying thereunto a linen cloth four or six times double, dipped in cold water, and new dipped as it begins to grow warm; for the cold repels or prevents the flowing of humours to the part, which otherwise would cause great swelling, and after turn blackish: And if upon neglecting to do so, a swelling should succeed, it may be discussed by fomenting night and morning, for an hour at a time, with water as hot as can be endured; for that will give vent to the humours to transpire through the skin, or dissolve them, so as to make them capable of returning back.

[Sidenote: _All sickness at the stomach to cure._]

Moreover, by means of water all sickness at the stomach may be cured, which is done thus: Take four quarts of water, make it as hot over the fire as you can drink it: of which water let a quart be taken down at several draughts; then wrap a rag round a small piece of stick, till it is about the bigness of a man's thumb; tie it fast with some thread; and with this, by endeavouring gently to put it a little way down your throat, provoke yourself to vomit up again most of the water: Then drink another quart, and vomit up that, and repeat the same the third and fourth time, if once or twice is not sufficient. You may also provoke vomiting by tickling your throat with your finger, or the feather-end of a goose quill; but the cloth round a skewer maketh one vomit with more ease, which is done with no trouble when the stomach is full. And by this way of vomiting, which will be all performed in an hour's time, that viscous and ropy phlegm in the stomach, which causeth the sickness, will be cast up, so that the party in that time will be free from all that inward disturbance, if you use the remedy at first; but, if the sickness hath continued for a time, it will require the same course once or twice more, which may be done in three or four hours, one after another, without any other inconvenience, besides that of being a little sore in the breast the next day, which will soon go off by the force of nature. Which remedy, by forty years experience, I look upon to be infallible in all sickness at the stomach, from what cause soever, and for all pains in the belly which seem to be above the navel; for these are all in the stomach, as by long experience I have found: Which pains are generally counted the cholic; but it is not so; for true cholics are always below the navel, in the gut colon. And by this means I have eased very great pains caused by eating mussels that were poisonous; and it is also a certain cure for all surfeits or disorders that follow after much eating. So that the lives of multitudes might be saved by this means, who, for want of expelling what offends, often die in misery: For, by thus cleansing the stomach at the first, the root of diseases proceeding from surfeiting, or unwholsome food, or any viscous humours from a bad digestion, are prevented; the stomach being the place in which all distempers at first begin. No man was more subject to sickness than myself before thirty years of age; but since I found out the way of vomiting with water, which is now above forty years, I never have been sick for two days together: For, when I find myself ill to any great degree, I betake myself to this way of vomiting, which in an hour's time restores me to ease, and perfectly removes my illness. And the same benefit all my family find in it, as do others also whom I can persuade to try the experiment, which is such, that no physician whatever can advise a better to the king himself, should he fall sick. For, in the first place, it is not a nauseous remedy, it does not make the patient sick, as the best of all other vomits do; and then it is a vomit which is at our own command, since we can leave off when we please: And it infallibly works a cure to all sick stomachs, from whatever cause.

[Sidenote: _Digestion to cause._]

Some few indeed pretend they are not able to vomit by this means: Now, if they cannot vomit, let them take a pint of water when they find themselves ill from eating, and do so every three or four hours, eating no more till they are hungry; and they will find the water digest and carry off what was offensive. The ingenious Dr. Cheyne, in his _Treatise of the gout_, affirms, that warm water drank freely in a morning fasting, and at meals, (and I say cold water is as good) hath a sovereign remedy for restoring left appetites, and strengthening weak digestions, when other more pompous medicines have failed. And he adviseth gouty persons, after excess either in meat or drink, to swill down as much fair water, as their stomach will bear, before they go to bed, whereby they will reap these advantages, either the contents of the stomach will be thrown up, or both meat and drink will be much diluted, and the labour and expence of spirits in digestion much saved, p. 44. ed. 4: And indeed I have found by long experience, that

nothing causeth so good a digestion as fair water; but this requires time to free us from the uneasiness that an ill digestion causeth, whereas vomiting is an immediate remedy, and frees a man from it upon the spot.

[Sidenote: _Other benefits of vomiting with water._]

We are told by Sir John Floyer, in his _Treatise of bath and mineral springs_, that vomiting with water is very useful in the gout, sciatica, wind, shortness of breath, hypochondriac melancholy, and falling-sickness; which distempers are generally derived from evil matter contained in the stomach, as is likewise giddiness in the head, and apoplexies, with which myself once seemed to be threatened: For, after eating a plentiful dinner, I was seized with giddiness, and the sight of my eyes became so depraved, that things seemed double, which was accompanied with a strange consternation of spirit; and having read, that apoplexies generally seize after eating, I immediately called for water, and, net daring to stay till it was warmed, I drank it cold, and by the help of my finger provoked vomiting: Upon which I did immediately overcome the evils I was threatened with, the symptoms before-mentioned being the same as did precede the fit of an apoplexy in another person, as himself afterwards told me, who died of it the third fit, about a year after.

[Sidenote: _Shortness of breath._]

As for people who are troubled with shortness of breath, it is certain from experience, that vomiting with warm water three or four times, will afford certain relief. And the same may be prevented by drinking nothing but water afterwards, either cold or warmed with a toast. For, upon doing this, the difficulty of breathing will apparently abate; which water, if you please, may be boiled with honey. And I knew one, who by this means, as he was advised by me, lived comfortably in this city two or three winters, but, having undertaken business which did occasion drinking strong drinks, was the next winter carried off by the distemper: Wine, ale, or brandy, being as bad as poison to people troubled with shortness of breath. So that nothing but water ought to be drank in that distemper.

[Sidenote: _Vomiting to cure._]

Some people are taken with violent vomiting, and the excess thereof in some hath been so great as to endanger their lives, yea, cause death: In which case water will be very helpful; for, if a pint of it warmed be drank after every vomit, it will prevent that violent straining, wherein lieth the danger of all vomiting, because to strain violently, when but little will come up, endangers the breaking of some inward vessel. And, besides this, the offending matter will be sooner loosened from the internal part of the stomach, and cast out, upon which the vomiting will sooner cease: For after this manner the famous Sydenham, a most honest writer, did overcome the cholera morbus, or vomiting and looseness, so common in his time, and was found by the weekly bill to kill more than now die of convulsions; for his way was to boil a chicken in four gallons of water, which made a broth not such differing from water, of which he ordered large draughts to be given, and some of it to be taken by clyster, till the whole quantity was spent, if the vomiting did not stop before; which did so take off the sharpness of the matter offending, and wash it out, that the party in a little time became well. And the same was the practice of Sigismundus Grafius, who commends pure water in a vomiting or looseness to be drank in large quantities; for thereby, he saith, the corrosive and sharp humours will be so weakened, that they will no more offend: And he saith, it may be drank cold if the patient be strong, otherwise let it be warmed.

[Sidenote: _Fluxes._]

And in common fluxes without vomiting, a quart or more of warm water drank, will so weaken the sharpness whereby the distemper is caused, that is will soon be overcome, and the gripings eased. And in the bloody flux, which is the most dangerous of all fluxes, the ingenious Cornelius Celsus adviseth a large drinking of cold water as the best of remedies: But then no other substance must be taken till the disease is cured. And Lusitanus, another great physician, affirms, _Cent. 1. Obser. 46._ that he knew one, who, being in the summer-time afflicted with the bloody flux, drank a large quantity of cold water, and thereby recovered. This large quantity of water, in these fluxes, doth so correct the sharpness of the humour offending, that it can have no power to cause pain, or corrode the vessels, and cause bloody digestions or stools.

[Sidenote: _Consumptions._]

Water also is a drink that conduceth above all things to cure consumptive people; for the digestion being weakened, is the cause of producing a hot fretting nourishment, which is injurious to the tender substance of the lungs, and which constringes and stops up the lymphatic vessels thro' which the nourishment is to pass to all the parts, so that by degrees the body for want of due supplies consumes: Which obstructions, and that acrimony which causeth them, will be opened and sweetened by the plentiful use of water,

if taken before the lungs become ulcerous. Which cure of consumptions by water is recommended in the writings of Dr. Couch, who, in his _Praxis Catholica_, tells us, that he knew a man cured very soon of a consumption by drinking pure water. And it is said by another, that some have been cured of consumptions by drinking no other drink but water, avoiding all malt liquors, and sharp wines: For wine or any other strong liquor is pernicious in this distemper, whose original is affirmed by Dr Coward to be always in the stomach, from some intemperance in meat or drink.

[Sidenote: _Flushes in the face._]

Some there are who are much troubled with flushing heat in the face, and others with a heat in the back; in both which cases, water used as common drink is the best remedy, with a spare cooling diet: And it is also excellent for such as have red blotches in their face, which proceed from a hot fretting blood, which by water-drinking, and a moderate diet, will be kept under: For as Dr. Duncan, before quoted, doth affirm, those who keep their blood cool and clean, are never troubled with breakings-out, like many others, who may be known to be drinkers of hot drinks, and to use a hot full diet, by their faces being full of blotches.

[Sidenote: _Cholic._]

Water is also commended by the learned for the cholic; large drinking of water hath been found to be an excellent remedy. And it is said by Fortis, that when he practised at Venice, he often gave cold water in the cholic, with good success. With whom an English physician, Dr. Wainwright, in his _Mechanical account of the six non-naturals_, concurs; for he saith, that water-drinkers are never troubled with the cholic, and that many thereby have been cured, when all other remedies failed: But in this case a quart at least is required.

[Sidenote: _Small Pox._]

And, in the Small Pox, water hath also been proved to be an excellent drink. Salmon, in his _Synopsis Medicinæ_, saith, that in this distemper you may safely give the sick fair water, of which, says he, they may drink liberally to quench thirst; the want of which plenty of drink, hath been the death of many a patient. Which opinion of his was right, as by experience I have found in two of my own children, when sick of this distemper; to whom, after I had given a gentle vomit of emetic tartar, I gave no other drink but water, and they both recovered safely, and were not in the least light-headed, as two others before were in the same distemper, when treated otherwise. And I remember that one Dr. Betts, being consulted in a case where the eruption did not come out kindly, ordered two quarts of cold water to be drank as soon as could be, upon which they came out according to expectation, and the party did well.

[Sidenote: _Burning fevers._]

It is also certain, that, in what we call burning fevers, water is found to be a safe and effectual remedy. It is said by Dr. Primrose, in his _Popular Errors_, that many great physicians have commended the drinking cold water in diseases, and they attribute to it the chief place in fevers, where the sick must drink largely; for thus taken it will quench all heat, p. 374. And Galen is said, by an English author, to reprove Crasistratus for denying cold water in burning fevers; and says, that this is a remedy for any fever, provided it be drank in great abundance. With which opinion I find Dr. Oliver to agree, who, in his _Essay on Fevers_, says, that in fevers we must drink oftner than thirst calls for it, and such draughts as are plentiful; and the drink he prescribes is either cold water or barley-water. Dr. Wainwright affirms also, that water is proper in fevers, and that the ancients gave as much of it as the patient could drink. And by another it is said, that if you give the patient nothing but water for three days, that in the third day the fever will be cured generally; but, if it is not, give for food a little barley-broth, and the fever will not exceed the seventh day. And by another we are informed, how one in a fever, that was past hope, being forbidden to drink water, which he greatly desired, did find means, in the absence of his nurse, to get a large potfull, which he drank off, and lay down again, being well cooled; after which he fell into a sweat, and so was cured. Dr. Cook of Warwick, in his book of _Observations on English bodies_, prescribes for the cure of fevers, first a vomit, and afterwards as much cold water as the patient can drink; and he saith, that, if he sweat upon it, the sweat must be continued as long as can be. And it is said by another, that it is an excellent remedy in fevers to drink a quart of hot water, and sweat upon it, being covered warm. Dr. Quinton, in his book of _Observations_, writes, that to one in a malignant fever, whose pulse was so low it could scarcely be felt, there were three quarts of water given, at several draughts, to make him vomit; but it did not operate that way, yet the event was this: It refreshed him much, raised his pulse, brought him into a breathing sweat, and passed off by urine; which lowness of the pulse I have often found to be raised in other cases, by drinking water plentifully. And I know a woman, who, tho' she in a fever had the advice of two doctors, yet became distracted; I bid the nurse give her a pint of cold water, which she drank up, and in three or four minutes came to her right senses; and desiring to drink more, she recovered. And I

have observed, that when in fevers the patient can relish no other drink, yet water is always drank with pleasure, as it also will always be after the eating of sweet things, that spoil the relish of other drinks; which is one excellence peculiar to water, and shews it to be most agreeable to the nature of mankind, tho' now so much slighted. And, besides this, it is a drink that will not turn sour in the stomach, as all fermented drinks will do, to the increase of distempers already begun there, by acidity or sourness.

[Sidenote: _Gout._]

And as for the gout, which Dr. Harris saith, in his _Anti Empiric_, is gotten either by high feeding or drinking much wine, or other strong drink; it may be cured, as that author affirms, by a very spare diet, and drinking water: According to what is said also by Sir Theodore Mayhern, who, in his _Medicinal Counsels_, adviseth to leave off all strong drinks in this disease, and drink only water. And Van Heyden saith also, in his _Treatise of help for the rich and poor_, that there is not any greater remedy for the gout than drinking water, not only by young, but old men; many of whom, he saith, have drank cold water for many weeks, which hath succeeded so well, though they were far gone in years, that they found great ease thereby, without that offence to the stomach, or hindrance of digestion, which some did not seem to fear. And he also commends the large drinking of water in the sciatica or hip-gout, he having often cured that distemper, by this means, in less time than could reasonably be expected. And the same I have found to be effectual in a pain in the shoulder, which had continued very bad for three months: For, being taken with a fever, I drank in one day about four quarts of water; which tho' it did not make me sweat, because I lay not in my bed, yet it cured me so that I slept well that night; and, in the morning when I rose, the pain in my shoulder was not felt, neither did it ever return. And the same success I have had in the pains of other parts; whereby, I judge, that, in all pains whatever, the drinking of water is proper, as well as in the gout: And accordingly I find cold water advised to be drank largely for the cure of the head-ach from hard drinking; that pain proceeding from the same cause the gout does, namely, from heat, as all pains do, that are not from bruises.

[Sidenote: _Inflammatory distempers & wind._]

It is said also by Dr. Wainwright, that in the itch, scurvy, leprosy, and all hot inflammatory distempers, such as pleurisies, rheumatisms, and St. Anthony's fire, water is a proper remedy; but he adviseth to drink it hot in some cases, as doubtless it ought to be done in pleurisies. He also saith, that water is proper in head-achs, catarrhs, vapours, falling-sickness, dulness of sight, melancholy, shortness of breath, scurvy in the mouth, and windiness in the stomach: And for this wind in the stomach, I, by long experience, have found it the best remedy, who in the former part of my life, through a disorderly diet, and drinking strong drink like others, was never free from windy belchings, and sometimes very sickish qualms after meals; from which at length I was delivered, by drinking only water at meals; so that for above forty years I have been seldom troubled: And, if I find myself troubled, a pint or more of cold water, in less than half an hour will set me free, by drinking of it.

[Sidenote: _Hard drinking._]

And that water is the best remedy for the mischiefs that come by hard drinking, experience teacheth; there being nothing that so effectually frees from these nauseating and reaching qualms the next morning, as the drinking a pint or more of fair water; which effectually allays the inflammation of the bowels, occasioned by strong or hot drink, which spoils the strength of the stomach, and of all other parts; nothing being a greater enemy to the vigour of the nerves and sinews, since by much drinking, men make themselves unable to stand or go; which effect would never follow, if liquors that abound with spirits were strengthening; nor would the fibres of the stomach be so weakened after drinking strong drinks, as to make men sick; which sickness will soonest be recovered by the drinking cold water, this being also the best remedy, if taken largely, for that heat of urine often occasioned by hard drinking.

[Sidenote: _Colds and bad digestion._]

In colds, water is the best of all drinks to prevent floods of rheum from the nose and mouth, as my long experience testifies, and therefore will prevent coughs; for a cough will seldom succeed a cold, if water is used from the first as common drink: And if, through neglect, a cough should become troublesome, the use of water, avoiding all wine and strong drink, will contribute much to the cure. Some order the water to be drank warm, but others say, that the drinking it cold vastly excells the using it hot in a cough. It is said by Van Heydon, that some may think it strange to advise water in such diseases, which most account to proceed from crudity or indigestion; but he says, that, in any disease where the case is dangerous, the use of water is the only friend to nature; cold being a preventer rather than a cause of crudity; since by all experience it is proved to be a promoter of good digestion. And at this time I know a woman, seventy-eight years of age, who for ten years past hath had a great cough, and spit much tough phlegm, that this present winter 1722, hath been persuaded to leave off both strong and small fermented liquor, and drink only water at

meals, and sometimes a dish or two of tea; and hath found herself much less subject to cough than before, and scarce coughs at all in bed, tho' subject before to cough very much in the night: She also drinks at bed-time half a pint of cold water, and the same quantity first in the morning, and finds more comfort by it at so great an age, than wine hath at any time afforded, Moreover, drinking of water is a certain cure for the heart-burning; as some affirm.

[Sidenote: _Heart burn._]

[Sidenote: _Strong drinks hurtful to children._]

It is generally the opinion of most physicians, that wine and strong drinks are not proper for children; and that the smaller and cooler their drink is, the better it will be with them; and that nothing conduceth more to the health of children than drinking water, which will prevent the foundation of those diseases that are caused in many by strong drink, and shew themselves in their more advanced age, wherein many also suffer much by the mother's ill custom of making them gluttons, by constantly cramming their stomachs with food, many being thereby destroyed among the children of the rich, before they come to the years of maturity; when the children of poor country people, who fare hard, stand their ground till full grown: For fewer children die in the country than in great cities, where luxury in diet doth more abound; which is one reason why so few house-keepers in London were born in it, the great supply of inhabitants being from the country, children being brought up more hardy there than in London, where great numbers are killed by over-eating or pleasing their palates. Which mischief would be in a great measure prevented by their being accustomed to eat less, and drink water; this by experience being found to make young children free from that frowardness, which is commonly caused by a sharp, and hot, or feverish blood, which engendereth wind, and causeth pain and gripes: for there is no pain but is the consequence of heat, or inward as well as outward inflammations.

[Sidenote: _Fair water equal to that at Tunbridge._]

To what hath been said may be added this consideration, that, when the best physicians are baffled by some distempers, they advise their patients to use the water of some mineral spring, tacitly acknowledging thereby, that all their prescription may be excelled by water. They pretend indeed to ascribe its effects to some minerals with which the waters are tinctured: But Dr. Baynard, in p. 438, of Sir John Floyer's _Cold bathing_, tells of a certain person who used to frequent Tunbridge, by which he found much benefit; but, being hindered from going thither one season, drank the same quantity of water taken from the pump of a spring in his own yard, which did him as much service: whereupon he wrote thus upon his pump:

Steel is a cheat; 'Tis Water does the feat.

And, indeed, if we consider how many diseases and pains proceed from a sizey, thick blood, which cannot pass as it ought to do through the finest pipes that convey the blood to the parts, pure water, without minerals, drank to the quantity of a quart or three pints in a morning, will attenuate or thin the blood sufficiently: Nothing, as Boerhaave affirms, being a greater diluter of thick blood, than warm water drank in great quantity. Which to thin the blood may be best, tho' to strengthen the stomach it is best drank cold, having the same effect inwardly, in some cases, as cold bathing hath outwardly; its use this way being also great.

[Sidenote: _Burns and Scalds._]

For water I have found, by long experience, to be of excellent use in burns and scalds; for in all burns and scalds, that are slight, if the part is plunged immediately into cold water, the colder the better, the pain will instantly be taken off; and it will fetch out the fire, if continued so long as will be required to do it by any other remedy. And if the burn be so considerable, that other remedies must be applied, none of which will take off the smart of themselves in less than two or three hours; yet if you apply cold water presently, after other applications are made to the part, the pain will immediately cease, till the remedy becomes effectual: So that the ease water will give in such cases, makes it of good use. Which remedy, as it hath not been discovered till now, appears to transcend all other remedies in this case; because, in a moment, the greatest smart will eased, if the water is cold, and will be felt no more, if the part afflicted be kept immersed in it till the fire is extinguished, either by the water, or the medicine applied. Besides, it is a remedy every-where ready at hand, which cannot be said of any other; which generally requires so much time to get it ready, that much pain will be endured, if blisters do not arise, which do much increase the trouble. If the part burnt, or scalded, cannot be dipped in water, you may apply water to it, with double linen cloths dipped therein, and new dipped as they grow warm; by which means I have cured burns and scalds in the face without blistering, when applied immediately before blisters did arise.

[Sidenote: _Ulcers from burnings._]

I once knew a large ulcer in the foot, made by the running of melted brass into the shoe, that was kept in hand by a surgeon nine weeks, without any probability of healing, because of the great inflammation that attended it; but the party, being a lover of angling, was persuaded to go with some others to Hackney-river: Some of them went bare-legged into the water, to come at a certain hole where much fish was sometimes found. The sport was so good, that the lame man having pulled off his stockings and plaisters, went in also, where he staid above two hours, and coming out again, the ulcer, which appeared very red and angry when he went in, looked pale; he put on his dressings, and came home, and in less than a fortnight his ulcers healed up; which doubtless was occasioned by the abating of the inflammation by the coldness of the water. And I have had an account also from an acquaintance, that was a surgeon to a merchant ship, that their gunner, at a time when the captain treated some friends on board, going to charge a gun that just before had been fired off, the cartridge he was ramming down took fire, whereby he was blown into the water, and had some of his fingers torn off, and it was about an hour before a boat could be got to take him up: But they found that the coldness of the water had almost stopt the bleeding, and the cure was effected so speedily, that other surgeons wondered at it; which he imputed to the water, which kept back the humours, by its coldness, from flowing to the part at the first: So that there was no impediment, from inflammation, to hinder healing; for the chief impediment to healing, is inflammation in wounds or ulcers. Moreover, to bathe with cold water, is affirmed by Dr. Lower to be a sovereign remedy for any hot swelling, if continued a due time at the first beginning; and it is affirmed also to be a good cure for the cramp.

[Sidenote: _Hot swellings._]

[Sidenote: _Sprains and hot swellings._]

And as for strains and sprains in the joints, cold water affords the best and most speedy remedy, as Van Heydon affirms; who saith, that, by bathing in cold water, all harm so received may by this remedy be cured more safely and more speedily than by any other, without loss of time, cost or trouble; for no more is to be done, as I have often found, than, as soon as can be, to put the part into a vessel of cold water for about two hours, which will prevent all swelling and pain, by repelling or keeping back the humours that otherwise would flow to the part. And if it should be the shoulder, or any other part, which is so hurt, that cannot well be immersed in water after this manner; water may be applied, by dipping towels folded up into it, and laying them to the part, as is done, in effect, to the wrenched joints of horses, about which, if you wind oftentimes a thick rope made of hay, and then cast upon it divers times a pail of cold water, the wrench will be cured; which experiment is now commonly practised by those concerned about horses.

[Sidenote: _Sprains in horses._]

[Sidenote: _Weakness of the joints._]

Bathing in cold water hath also been found to be a good remedy to strengthen weakness in the joints, as Sir John Floyer, in his treatise of _Cold Bathing_, hath shewed; and which by experience I found to be true on a certain woman, who complained of great weakness and pain in her ancles: I advised her to dip the part in cold water every morning for a quarter of an hour, and do the same at night; and in about twenty days she became as strong in that part as she was in the other. And Sir John tells us of a boy who could not stand, his limbs were so weak, that, by bathing in cold water, perfectly recovered his strength in a little time.

[Sidenote: _Pain in the head._]

Great pain in the head hath been also cured by this means; for we are told by Van Heydon, that Sir Toby Matthews had for twenty years been troubled with great pain in one side of his head, and a great defluxion of rheum from his nose: but he at last was cured, by applying cold water to the part every day for about a quarter of an hour: Upon reading of which, I tried the experiment upon myself, who for a long time had been troubled with the running of much clear water from my nose, with great spitting of thin rheum; for I let a water-cock run upon the mould of my head every morning, by which, in about six weeks time, I was eased of my trouble. And since that, I had a credible information of a certain servant maid, who was afflicted greatly with a rheumatism, and an intolerable pain in the head, who being put into St. Thomas's Hospital, her nurse was ordered by the doctor to apply to her head towels four times double, dipt in cold water, changing them as they became warm, which she was to continue doing four or five hours; in which time she was freed from that pain in the head, and was afterwards cured of the rheumatism by other means.

[Sidenote: _Want of sleep in fevers._]

The want of sleep in fevers, may be cured likewise by the application of cold water: For to a near relation in a fever, who could not sleep for three days and three nights, I ordered a towel to be several times folded up, then to be dipped in water, and a little wrung

out, and so laid upon her forehead, and to be new dipped as it grew hot; which in about two hours time so cooled her head, that she fell into a sleep, and continued in it five hours: And I ordered the same to be done the next night, with the same success. Dr. Cockburn, in his treatise of _Sea-diseases_, orders, for the want of sleep in fevers, to dip a towel four times doubled in oxycrat, which is six parts water and one part vinegar, to be bound about the head and temples; which, he saith, will cause sleep with wonderful success. But cold water only will have the same effect, as I often have proved.

[Sidenote: _Swoonings._]

And that the use of cold water, in swooning, is of great effect, common experience teacheth: For, if a dish or cup of cold water is thrown strongly upon the face, the person in an instant will recover, tho' for a time he seemeth dead, and perhaps might not have recovered in some cases, if cold water had not been so applied; such faintings being sometimes deadly, which proceed from poisonous vapours ascending up to the brain from a foul stomach: For such effects there are, as I have found by experience, who in my young days did swoon away twice; at both which times I was sensible of a collection of wind in my stomach, from whence I plainly felt a fume or vapour ascend to the head, that in an instant deprived me of all sense: But being both times in the company of a person who had seen the thing tried, he dashed some cold water against my face, which I remember made me start, as if I had been suddenly awaked. And I am apt to think, that some die in such a fit, when none are near to help them; and especially when so taken in their sleep, which I believe none need fear, who live temperately, or that eat no suppers; none who have refrained from suppers; having been ever found to die in their sleep.

[Sidenote: _Bleedings at the nose._]

Dangerous bleedings at the nose have also been cured with cold water largely drank, syringing cold water up their nostrils, and applying towels round their necks dipt in cold water, changing them as they grow warm; for it is said by a good writer, that this will so cool the heat of the blood, and by the coldness of the water syringed, up the nose, so contract the mouths of the veins which bleed, that it will put a stop to the bleeding. Such bleedings have also been stopt by dashing cold water often in the face, as a French writer hath affirmed, whose name was Flammand; and the same also is asserted by Cook, in his _Marrow of Surgery_.

[Sidenote: _Small cuts._]

Cold water is an absolute cure for all small cuts, in the fingers, or other parts; for if you close the cut up with the thumb of your other hand, keeping it so closed for a quarter or half an hour, this will infallibly stop the bleeding: After which, if you double up a linen-rag five or six times, dip it in cold water, and apply it to the part, binding it on; this, by preventing inflammation and a flux of humours, will give nature time soon to heal it without any other application, as is seen in the common practice of surgeons when they let a man blood; for all the application they make to the vein so cut, is a pledget of linen dipped in cold water, and bound on with a fillet: For all wounds, without loss of substance, will heal of themselves, if inflammation be prevented, and the lips of the wound are kept close together.

[Sidenote: _Bitings of a mad dog._]

We are also informed by Van Heydon, that in his time some were of an opinion, that a person bit by a mad dog might be preserved from that symptom, called, the fear of water, which generally follows, and proves so mortal, by applying cold water to the place bitten: And this, he says, they conceive to be no unlikely thing, if there is any credit to be given to what Cornelius Celsus writes, who saith, that the only remedy in this case is, to throw the party who hath the fear of water upon him, into a pond or river, and, when plunged over head and ears, to keep him in the water till filled with it, whether he will or no; and by this means both his thirst and dread of water will be cured. For, if this immersion be of use when the person is so far gone, why should it not be of greater force in preserving from it, if speedily applied, and repeated? Now, tho' this is mentioned by him as a probable opinion, yet experience in our days shews, that the plunging the patient into the salt water, either of the river of Thames about Gravesend, or in the salt springs in Cheshire, is the best means to prevent any evil succeeding the bite of a mad dog; they must indeed be dipped so often, as to be almost drowned before the danger is over: But it is a question whether the saltness of the water contributes any thing to this cure, since Boerhaave, the present professor at Leyden, affirms, that when men bitten by a mad dog are arrived to the fear of water, called an hydrophobia, they may be cured by blinding the patient's eyes, and throwing of him into a pond of water often, till he seems not to be afraid of it, or but very little, and then force him to drink large quantities.

[Sidenote: _Falling-sickness._]

And we are told by Dr. Edward Browne, that a person troubled with the falling-sickness, by happening to fall into a cold spring, (I suppose it was in the time of his fit) was freed from his distemper all his life after: And he saith, there is no need of preparing the body for it in this, as in some other cases. But the patient, when plunged into a cold bath, ought to continue in the bath each time about three or four minutes; for, in plunging over head and ears at his first entrance into a cold bath, the brain will be so sensibly affected, as to be relieved from the distemper, which is a kind of convulsion proceeding from an inflammation, or some other cause; but we want more experiments to confirm this notion: which notion may be worth noticing, that the thing may be tried in others, to see if it will succeed as it did in this person. For it is said by the ingenious Dr. Pitcairn, a Scotsman, sometime professor at Leyden, that there is no such thing as the art of curing, but only the practice; remedies were found out by chance, p. 264, of his works. For when remedies thus happen to be discovered, and prove often to be effectual, the remembering that remedy, to apply it in a like case of practice, brings reputation to the prescriber; but, if it fails, some other experiment must be tried, which, were physic an art, need not be done, because the rules of art are certain, and men depend upon them as such.

[Sidenote: _Madness & melancholy._]

It is also said by the same Dr. Browne, that madness and melancholy, with all their retinue, may find better effects from the use of bathing in cold water, than from other violent methods, with which people so afflicted are now treated; for, says he, that which will make a drunken man sober in a minute, will certainly go a great way towards the cure of a madman in a month. Now it is most certain, to my own knowledge, that, if a drunken man be plunged over head and ears in cold water, he will come out of it perfectly sober: And some I have known, that in such cases have been recovered by barely washing their heads in cold water. Which fore-mentioned opinion of Dr. Browne is confirmed by the practice of Dr. Blair, who, in a letter to Dr. Baynard, declares, that he cured a man raving mad, who being bound in a cart, stript off his clothes, and blindfolded, that the surprise might be the greater; he on a sudden had a great fall of water let down upon him from the height of twenty foot, under which he continued so long as his strength would permit: And, after his return home, he fell into a sleep, and slept twenty-nine hours, and awaked in as quiet a state of mind as ever, and so had continued to the time of writing that letter, which was twelve months. Distraction also in fevers, of which there are divers instances in the history of _Cold Baths_, has been cured by being plunged in cold water. _See p. 226._

Which relation seems to make that a more probable truth, which was related in a letter from Sir John Floyer, to Dr. Browne, and printed by that doctor; that in Normandy they immerse fools, or dip them in cold water to cure them: A hot brain being the cause, perhaps, of several disorders in the understanding, and is in great part found to be true in the ridiculous behaviour of some drunken men, which, when their heads are become cool, abhor what they before did or said. Now, if such dipping would cure fools among us, great numbers might be made more happy than they are by being so dipped, before they have beggared themselves by imprudence.

[Sidenote: _King's-evil._]

Dr. Browne, in his discourse of _Cold Baths_, affirms, that to bathe in cold water hath been found to be the quickest, safest, and pleasantest cure for the king-evil; and he tells us, in p. 85, of a Yorkshire gentleman, who was grievously afflicted with this distemper, having great ulcers in the glands of his neck, which were so much inflamed, as to bring him very low; but, being advised by Dr. Baynard to bathe in the cold bath, he in a month's time was perfectly cured, his ulcers being healed up, contrary to the opinion of the most learned physicians.

[Sidenote: _Jaundice, swelling, inflamed eyes, and pains in the joints._]

We also find mention, in the description of the Scottish Islands, of an odd remedy commonly made use of there for the cure of the Jaundice; which is this: They strip the party naked, lay him upon the ground on his belly, and pour unawares upon his back a pail of cold water. And also pains in the joints, as Dr. Curtis tells us, will be cured, by holding the part under the stream of a pump or cock; and fomenting with cold water, is commended as good to assuage hot swellings. And I know a person who had often been subject to blood-shot or inflamed eyes, who afterwards, upon the beginning of the same distemper, took, by advice, a ball of linen rags, dipped them in cold water, and applied them to the part, cooling them by new-dipping as oft as they grew hot: Which application was continued three hours, in which time the humour was so repelled, as to be troublesome no more; for the party, to my knowledge, hath had no sign of that distemper since, tho' the same had been very troublesome many times before: And the same others have tried with the like success.

[Sidenote: _Defluxions on the eyes._]

It is also advised by Dr. Gideon Harvey to wash the eyes well twice a day in cold water, as the best remedy to prevent defluxions on them, and preserve the eye-sight, which it greatly comforts. And this I have found true for many years, my eyes being often apt to be dim and stiff, so that I could scarce open my eye-lids; which, upon washing for a minute with fair water, hath been felt no more for a good while after. Besides which benefit to the eyes, authors say, it is also good to preserve the memory, if the whole forehead be washed twice a day; and it is also a certain cure for itching in the eyes. And indeed, washing with water will free mankind from a troublesome itching in any other part of the body, let it be never so private; as Cook, in his _Observations on English bodies_, doth expresly declare from experience. And Wedelius affirms, that violent itching in a man's cod was so cured by him; and, if the other sex would make use of it, a single life would be less uneasy than it seems to be to some.

[Sidenote: _Callosity & sore feet._]

Some people are troubled with a callosity, or hardness of the bottom of their feet, which is so troublesome, as to be a hindrance to their easy walking; for which a cure is prescribed by Dr. Cook, that is, to soak them well in warm water, till the hardness is softened, and then scrape it off with the edge of a knife: And if the feet burn with any unnatural heat, and are tender, it was advised by Mr. Rumsey, in his _Organon Salutis_, to bathe them daily in cold water. Others affirm, that to bathe tender feet often in hot water will cool them, by giving vent to that which is offensive; and it is useful in a cough.

[Sidenote: _Scurvy._]

The plentiful drinking of water is commended in the scurvy, whether hot or cold, by Dr. Pitcairn, to dissolve the scorbutic salts, and carry them out by urine; but this is a distemper that Dr. Cheyne affirms is difficult to cure, that nothing but a total abstinence from flesh, fish, and strong liquor, will overcome the scurvy, p. 127, whether they are acids or alkalies. But tho' weakness and faintness commonly attends on this distemper, yet myself, who have been formerly extremely troubled with the scurvy, which often made me faint and weak, and my pulse so low as scarcely to be felt, found at last that the pulse would infallibly rise upon drinking a pint or more of cold water, and in a little time I should again become brisk and strong: for I have often observed, that, upon a disorder of the stomach, the strength of the bodily members soon would fail, and as easily be recovered when the disorder of the stomach was removed; which requires temperance and cooling diet, when distempered, especially in drink.

[Sidenote: _Asthma & consumption._]

To what hath been already said, I will add an account, taken from a credible person, of a man in the parish of Shoreditch, who was desperately ill of an asthma, or shortness of breath, and deep consumption, for which he had tried many remedies to no purpose. At length he was advised by a physician, being poor, to drink no drink but water, and eat no other food but water-gruel, without salt or sugar; which course of diet he continued for three months, finding himself at first to be somewhat better, and at the three months end he was perfectly cured; but, for security's sake, he continued in that diet a month longer, and grew fat and strong upon it. But his diet he had no mind to till he was thoroughly hungry, and then he did eat it with pleasure; in which perhaps consisted the best part of his cure, it being an advantage to health never to eat till hunger calls for food.

[Sidenote: _Cough cured._]

And I remember a young woman, a burnisher of silver, who had a desperate cough, for which she had taken many things of an apothecary to no purpose; at length the journeyman told her, his master said, he could do no more:

But, said the fellow, I would advise you every morning to wash behind your ears, and upon your temples, and on the mould of your head, with cold water: which she told me she did, and was perfectly cured of her cough by that means. And for a hoarseness that comes upon a cold, the dipping of a handkerchief five times double in very hot water, and holding it to the mouth and nose, new-dipping it as it becomes cold, is commended by Dr. Alexander Read as a good remedy.

[Sidenote: _Hoarseness._]

[Sidenote: _Difficulty in making water._]

There are divers other cases wherein the use of water hath done much good. An ancient practiser in physic told me, that in many difficulties of making water, he had advised the party to put his yard into water as hot as he could endure it, which in a minute did cause him to make water; and that women have had the same benefit by sitting over hot water. And he often had advised them who were costive, and went to stool with great difficulty, to sit over a pot with hot water in it; which soon was attended with an easy dejection of stool, the body drawing up the vapour, which provoked expulsion of the excrements without much straining.

[Sidenote: _Costiveness._]

[Sidenote: _Children unquiet._]

And it hath been observed, that froward children have been made much more quiet, by washing their lower parts every morning with water, to wash off the salts of their urine, which usually stick in the pores of the skin, and are fretful and uneasy; and nothing cures their soreness about those parts like it. Nor is there any thing more effectual to cure men who are gauled by riding, than to wash themselves well when they go to bed with cold water; and washing the bare breast every morning with cold water, will make those hardy who before were apt at every turn to take cold. To which I will add what Sir Theodore Mayhern affirms in his _Medicinal Counsels_, that in most diseases

[Sidenote: _Head diseases._]

[Sidenote: _Pains in the ear._]

of the head, there is nothing better than to bathe it with cold water. Which, in a desperate pain of the ear upon taking cold, I have found to be true; for the pain did vanish upon applying to it about 30 minutes a towel doubled up often, and wet often in cold water; and tho' it returned again, yet ease was soon obtained the same way, and the cure perfected in four times doing: Which cure of a pain gotten with cold, by a cold application, will not seem so strange, when we consider, that, in the northern countries, mortifications from cold are nowise to be cured but by applying cold snow; as travellers into Denmark and Sweden do affirm.

[Sidenote: _Curtis's opinion of water._]

In short, water, when rightly made use of, appears, from the accounts before-mentioned, very effectual to prevent and cure many diseases; but more especially the inward use thereof: For to use the words of the ingenious Dr. Curtis, in his _Essay for the preservation and recovery of Health_; the habitual use of water for common drink, preserves the native ferment of the stomach in due order, keeps the blood temperate, and helps to spin out the thread of life to the longest extent of nature; it makes the rest at night more quiet and refreshing, the reason and understanding more clear, the passions less disorderly; and, in case of eating too much, a large draught of cold water vastly exceeds any other cordial to cause digestion: water being not so cold and lifeless, he saith, as many imagine. Besides which commendation of it by this doctor, it is certainly a drink that will not ferment in the stomach, nor turn sour, as wine and strong malt-drinks will, to the hindering of a good digestion, which all acidity in the stomach certainly doth, when it abounds there; and is best corrected by weakening or making it less sour, by drinking good store of water, as the experience of above forty years practice hath assured myself, and many others. For tho' water is accounted a contemptible drink, yet by beginning to make use of it about thirty years of age, before which I was often out of order, and continuing the use of it ever since, drinking very little wine or strong drink, I have attained to the age of seventy-four years, when thousands in the meantime, who delighted only in drinking strong beer, wine, and brandy, have not lived half so long: which makes good that saying in the Scriptures, that _Wine is a mocker, and strong drink is raging, and he who is deceived thereby is not wise_, Prov. xx. 1., since it noway contributes to long life; for it is certain, that thousands in the world live as long who drink no strong drink, as any drinkers of it do. Some indeed, from an extraordinary strength of nature, have been hard drinkers, and yet die old; but for one who does this, perhaps an hundred are destroyed by it before they come to half the time of life: and generally we shall find, that very strong and healthy constitutions, at the long-run, are ruined by riot and excess, there being no certain safety in any way of living, but that of temperance and moderation. Nature in some may, a long time, withstand the abuses offered to it, but at last it will yield to its enemies; and those who live the longest in an intemperate course, might, from the strength of their constitution, have lived much longer, had they ate less, and used themselves to drink more water; which drink, as it is most friendly, and longest will preserve the life of a strong constitution, so it is absolutely necessary for those that are weak and sickly, and are naturally subject to the gout, the stone, shortness of breath, wind, ill digestion, and such like.

[Sidenote: _Useful in Vomiting._]

But the chief use of water, in preserving of health, is by using of it as a vomit, as before was shewn, which is an infallible and the most speedy remedy that was ever found out for any stomach sickness, or pain there; for to vomit with warm water, will effectually remove it in one hour, and be a means to prevent great fits of sickness, and preserve the lives of many thousands to old age, by cleansing the stomach from that tough, slimy, or corrupt matter that offends, and is the cause of all mortal diseases, especially of an apoplexy, which, tho' counted a disease of the head, yet hath its original from a foul stomach, which nothing doth so effectually cleanse as vomits; according to Dr. Curtis, who saith, that vomiting with warm water, or carduus-tea, is very beneficial to bring up

that which fluctuates in the stomach, and that tough, ropy phlegm, which sticks fast to the wrinkles and folds of that bowel, and which purges do often pass over, and cannot remove. Which way of vomiting with warm water, is ten times more easy and pleasant than that which is effected by the use of nauseous tea made of carduus, which physicians sometimes advise; and it is also such as can do no harm by violence, as other vomits made from antimony sometimes do, for want of drinking after each vomit a pint or more of water-gruel, or warm water, when you vomit with water.

And here it may not be amiss to relate what I some years ago discovered, in order to mens freeing themselves from sickness that may happen after eating; for being invited to dine at a certain table, where there were several good dishes of meat, I was over-persuaded to eat more than I should, and in a little time after dinner found myself began to be sick. I went out, and in a private place attempted to vomit, by tickling my throat with my finger, but could not vomit as I designed; only by this means I raised up two or three mouthfuls of thick, tough phlegm, upon which I found myself better, and my sick qualm went off. I took the hint it gave me, and have done the same several times since, and find that the getting up the phlegm, which, like yeast upon beer, works up to the mouth of the stomach, a man may free himself from some kinds of sickness after eating. And I remember it is an advice given by one Vaughan, in a book long since printed, intituled, _Directions for Health_, for men who feed high, to put their finger in their throat when they rise in the morning, to make themselves puke, or void the phlegm which can be raised, as an excellent way to preserve health; and it is said also to be an absolute preservative from the gout, by a good writer.

[Sidenote: _The quantity of water needful._]

I will conclude with this note, that, in such distemper where water-drinking will be available for a cure, the same must not be drank sparingly, but plentifully; as (for instance) to ease the gripings in a looseness or flux: for, if but a pint of water should be drank, ease would hardly succeed; but, drinking in about an hours time a quart or three pints, the sharpness and evil quality of the humour offending, will be so far diluted or weakened, that immediate ease will follow. If the season be too cold to drink cold water, you may warm it a little upon the fire, or put a hot toast of bread into every pint. And the same is true in fevers, or in pains from gravel or the cholic: A small quantity will not be effectual in these cases; for in the cholic a quart is necessary, which ought to be carefully noted; and, in a fever, a little water will rather increase the burning, which large draughts, often drank, will soon take off. Rest, fasting, and drinking much water, after a vomit or two, is a course that never yet hath failed to cure fevers, by clearing the stomach of that sordid filthiness which causeth the distemper: for a happy issue will certainly follow such a course, if the fever is simple, and not complicated with such other distempers which will resist all remedies: For in many cases nothing can prevent mortality, as is evident by the death of the best physicians themselves, and by the death of many who consulted with them for a cure, since many die under the hands of the most able doctors, as well as quacks.

[Sidenote: _Grief and frights._]

I will add to what hath been said, one experiment more, that is very material: And that is, being very hypochondriacal, and of a melancholy temper, I have often been strangely dejected in mind when under grief for some misfortunes, which sometimes have been so great, as to threaten danger to life; in which fits of grief I always found the parts within my breast very uneasy, and sometimes continued long: But now I have found a good remedy; for, upon drinking a pint or more of cold water, I find ease in two or three minutes, so that no grief seems to afflict. Which experience I discover for the sake of others in the same circumstances, being certain, that the stomach sympathizeth with the mind, and this becomes the cause of that uneasy sensation perceived there, for which, cold water I have found to be the best remedy in myself, and I believe others may find the same benefit, who wilt make use thereof upon the like occasion. And it gives also relief to people under frights, which sometimes have been very fatal, even unto death.

[Sidenote: _Vapours._]

There is also another experiment that I have often seen of good effect; and that is, that if persons, subject to what is called vapours, or that are afflicted with fits, commonly called _the fits of the mother_, will but drink water when they find their fits approach, it will immediately yield relief. There is in this case a mealy julep, prescribed by Dr. Bates, which is, to take a spoonful of fine wheat-flour, an ounce of fine sugar, and a pint of water, brew them together, and drink it off: This is pleasanter than water alone; but water of itself will be as effectual, or rather better, as hath been often proved upon persons in those fits.

[Sidenote: _How to distinguish Water._]

Some perhaps may desire to know how to distinguish good from bad water. And the way to do this is, by the taste and scent; for being purely fresh, not salt, nor sweetish, nor ill-scented, it is good, provided it be pure and clear: Of which kind is the common water used in London, when well settled, or in fair weather. As for those who are curious, and will be at the charge, they may procure the best water for drink by distillation, either in an alembick, or in a cold still used in drawing any cold water from herbs; for no earthly or metallic substance, nor any kind of salt will rise in distillation: So that the water so distilled will be pure, and admirable to drink when cold, and will keep as long from stinking as any of the cold distilled water in the apothecaries shops; according to what Dr. Quincy hath affirmed about it in his _Dispensatory_.

Those who have not the conveniency of distillation, may boil it a little as they do for tea; for then, when kept a while after it is cold, it will become more fine, by suffering any mixture contained in it to settle to the bottom of the vessel, and that will render it still more pure: In short, all water that will make a good lather with soap, is wholesome to drink without boiling, but none else.

[Sidenote: _Pains in the stomach._]

Since the collecting together the fore-mentioned accounts, I have met with a book written by Dr. Boerhaave, the present professor of physic at Leyden in Holland, who affirms that drinking water, made very warm, is a good remedy to pacify griping pains in the stomach; and that it is proper to bathe wounds in the face with it, when they come to be just healed, so that the place be kept continually wet, which I conceive is best done by applying often linen cloths wet, and binding them on till they begin to be dry, for this will prevent scars: And he saith, that warm water is better to attenuate or thin the blood than cold.

[Sidenote: _Fevers._]

There is published lately a book of experiments made with water, by Dr. Hancock, a divine, called _Febrifugum Magnum_; wherein he saith, that drinking a pint or a quart of cold water in bed will raise a copious sweat, and cure all burning fevers, which at once taking hath done the business: It will raise a sweat without much more covering than ordinary. And he further affirms, that the same taken at the beginning of the cold fit of an ague, and sweating upon it, at two or three times taking, will cure that distemper. A large quantity of hot water, I know, hath been advised to take off the cold fit of agues, but the party was not ordered to sweat. Which discovery of the reverend doctor about fevers, is confirmed by the following accounts, which I received from a worthy gentleman, Mr. Ralph Thoresby, F. R. S.[1] to whom they were transmitted by Mr. Lucas, a pious and learned gentleman of Leeds in Yorkshire, who says, that

[1] Author of _Ducatus Leodiensis_, or Topography of Leeds, which the present learned Bishop of London, in his preface to the new edition of Cambden's Britannia, stiles, _An useful and accurate Treatise_.

'One Captain Rosier fell into a violent fever, which as soon as he perceived, he said he must have some cold water. The gentlewoman, at whose house he lodged, not thinking that proper, boiled the water (unknown to him) and put some spirits therein, and sent it up cold; but he smelt it before it came to his head, and refused to drink it, saying, he knew what he did, for he had several times tried it. Afterwards, some clear water being brought, he drank it, sweat profusely, and was well the next day.

'Another captain of a ship also took the same method, when he, or any of his men, fell into a fever; which had the desired success.'

Mr. Lucas adds, in another letter to the same gentleman, 'That his own wife fell very ill of a fever; she drank water, sweat very much, and thereby recovered.'

[Sidenote: _Colds._]

All which instances corroborate the new way of curing fevers, so lately discovered in this city by Dr. Hancock; who also saith, he has had long experience of curing common colds with cold water; and this is done by drinking a large draught of water at going to bed, another in the night, and another in the morning: which, he saith, will soon thicken and sweeten, and digest that thin sharp rheum that provokes coughing to no purpose; for the rheum, when thin, is hard to be brought up; but, when thickened, it will come up easily, and the cough will soon go off. Which agrees with what I before affirmed from my own long experience.

[Sidenote: _Good for the breath._]

He also affirms from his own experience, that using sometimes to take a walk of eight or ten miles in a morning, he found that water gave twice as good breath for that purpose as wine or ale; and, if it would do this for a man who had no asthma, he doubts not but it would do the same in a person troubled with one. And he also affirms water to be the best remedy for a surfeit; to the truth of which

I can testify by long experience.

[Sidenote: _Rheumatism._]

He also affirms, that drinking cold water hath been found good in rheumatisms, and that to one so afflicted he had advised to drink it as he lay in his bed, and it took off the fit; but if hot water attenuates the blood most, as Boerhaave affirms it is then best to drink of it warm daily to a good quantity: For, as Pitcairn observes, it is then the best dissolver of all kinds of salts in the body, which it will carry off in the urine, if drank plentifully; for by urine salts are evacuated, as is evident by the taste.

[Sidenote: _Gout in the stomach._]

And it is his opinion, from the long experience he hath had of the effect of water in keeping the stomach in order, and making it tight and strong to perform its operations, and digest all humours, that it will cure the gout in the stomach; and perhaps it may do it better than wine, which I have known to fail. And I do not wonder that the same liquor, which is the principal cause of the gout in other parts, should not be a help in that part, but rather kill, as it often is found to do, tho' the strongest wine is drank.

[Sidenote: _What sweating most natural._]

In short, he affirms, and that with great reason, that sweating in fevers, by drinking cold water, is more natural than to do it with hot sudorifics, which often do harm in the beginning of fevers, except good store of cooling moistning liquors are drank with them, they being more apt to inflame than cool and quench heat in the body; and for that reason sweating hath not been often advised by physicians, because they were ignorant of this way of sweating to cure fevers, by drinking cold water.

Which cure, he said, did succeed in one who was his relation, at the fifth day after his falling sick; to whom he gave a dose of water after he was in bed, and he sweated profusely for twenty-four hours, and thereby was cured. Half a pint, he saith, is enough for a grown child; a pint to a man or woman, tho' if they drink a quart, it will be better. And in scarlet fevers, small pox, or measles, tho' the water will not cause sweat, yet it will so quell and keep under the fever, that the eruptions will come out more kindly; which is a confirmation of what before was said about Dr. Bett's prescribing two quarts of water, when the small pox did not come out kindly; the water afforded matter to fill them up, according to what the author observes of a certain person, in the history of _Cold Bathing_, p. 347., that he could give an hundred instances where people of all ages have been lost, by being denied drink in the small pox,----for it hinders the filling of the pustules.

[Sidenote: _Plague._]

And Dr. Hancock sets down an account of the author of the _Free-thinker_, concerning a woman, who in the last great plague fell ill of that distemper, who got her husband to fetch her a pitcher of water from Lambs-conduit; she drank plentifully of it, but did not avoid the cold, and so did not sweat, however she was cured. And he gives us another relation of an Englishman, formerly resident at Morocco, that fell ill of the plague at that place, and, getting water to drink, fell into a violent sweat, and recovered: From whence the doctor concludes, that water is good in the plague; agreeable to what is related in Sir John Floyer's book of _Cold Baths_, wherein it is said, that but two died of the plague who lived over the water upon London bridge, p. 223, the coolness of the air being supposed to contribute to their health who inhabited on the water in that manner, their blood being cooler than others: It is said also, the watermen escaped better than others.

[Sidenote: right pointing finger icon]

I will here add to what the doctor hath said before, concerning the cure of fevers, that if the fever be accompanied in the beginning with any great illness at the stomach, nauseating or vomiting, it will be the surest and safest practice to clear the stomach first, by vomiting with warm water, as before directed; for I cannot believe it possible for the stomach to be cleared from foul humours by sweating. It may do, if no great sense of disorder is perceived there; but it will certainly be safest to cleanse the stomach first, which is the place where all diseases have their original; for then sweating with cold water afterwards may turn to good account. Indeed I have not made any trial of it since the doctor's book was published, but I have a very good opinion of his accounts therein given concerning the benefit of water, having had so much experience thereof in my own practice for above forty years; for so long it is since I first began to collect those accounts, and make those experiments, which are herein made public for the benefit of all. I will only add, that in a book, intituled, _Organum Salutis_, p. 50. written by Judge Rumsey, he saith, he never found any thing more useful for the health of man, than to drink first in the morning half a pint of cold water; and this will contribute much to the cure of blood-shotten eyes.

[Sidenote: _Pag._ 42, 43, 44.]

Since the last edition of this work, there hath been published _An Essay of Health and long Life_, by Dr. Cheyne, wherein this truth is asserted too, ‘That water was the primitive, original beverage--(and happy had it been for the race of mankind, if other mixt and artificial liquors had never been invented) and that water alone is sufficient and effectual for all the purposes of human wants in drink. Strong liquors were never designed for common use, tho’ now we see the better sort scarce ever dilute their food with any other liquor: And thereby we see their blood becomes inflamed into gout, stone, rheumatisms, raging fevers, and pleurisies; and their passions enraged into quarrels, murders, and blasphemies; their juices dried up; and their solids scorched and shriveled.’ This author, p. 46., exclaims against strong drinks, as the root of one half of all the human miseries; but finds they are unwilling to leave them off, pretending the danger of all sudden changes. But he alledgeth, ‘That he hath known good and constant effects from leaving off suddenly great quantities of wine, and flesh-meats too, by those accustomed to both; and never observed any ill consequences from it in any case whatsoever; but that broken constitutions have thereby lived longer, and grown better, by so doing.’

Some few, and but very few, have pretended, that by leaving off wine and strong drink, and using only water, they found their bodies weakened: But this perhaps may proceed only from the same fancy which made the lady believe her doctor could not cure her, because he did not keep a coach. There may be some constitutions that water doth not agree with, even as cheese will not agree with some: Nay, I once met with an ancient woman, who affirmed, she could not, and never did eat bread. And there are so few in comparison to them who have found benefit by the use of water, to those who have not, that no wise man will refrain on their account, till, upon trial, he really finds it will not agree with him.

One of the most ingenious watch-makers in London, very lately, from a long continued flux, was very much weakened, and entirely lost his appetite, so far that he could eat no food whatsoever: He had the advice of an able physician, his intimate acquaintance, who could not give him any relief: He, upon reading my book, came to ask me, whether I thought he might venture to drink water? I thereupon prevailed with him to drink half a pint of cold water going to bed, and half a pint in the morning: He, tho’ an immoderate drinker of wine before, was so far from being injured by it, that in a fortnight he began to eat, and in about a month recovered as good a date of health and countenance as he had before.

It hath been objected by some few, that drinking of water maketh them costive: which well considered, is an argument that it strengthens the bowels; for all fluxes proceed from weak bowels, and are an enemy to the strength of the bodily members, no persons being in health, as Dr. Baynard affirms, but those who evacuate figured excrements, which weak bowels never do; so that firm excrements tend most to strength, provided there be an evacuation one in a day, which is enough for them who through temperance live wisely, and do not destroy themselves by gluttony.

SOME RULES FOR Preserving Health by Diet, _Collected from Physical Authors._

[Sidenote: _Diet will cure diseases._]

In a little treatise, intituled, _Kitchen-physic_, written by Dr. Cook, the author declares, he can hardly be told of any disease which he cannot relieve or cure by a proper diet, p. 39. And in the same book we find his opinion to be this, that all tender sickly people, and all aged and decrepid persons, ought to eat often, and but a little at a time, because weak and wasted bodies are to be restored by little and little; and by moist and liquid food also, rather than by solid, because moist and liquid diet does nourish soonest, and digest easiest.

[Sidenote: _Feeding much, bad for weak people._]

Those, he saith, that eat much, and get little strength by eating, shew, that they have used themselves to too full a diet; and the more you cram such bodies, the less they thrive by it, but rather grow worse and worse: Because by much feeding you do but add to the bad humours wherewith the body is already filled, which should rather be wasted by purging, and using a spare diet.

[Sidenote: _A spare diet, what._]

And a spare diet he describes to be this, that we never eat at once till the appetite is fully satisfied, and never to eat till we have an appetite; and men never have a true appetite till they can eat any ordinary food: And he adviseth to keep constantly to a plain diet, for those, he says, enjoy most health, and live longest, that avoid curiosity and variety of meats and drinks, which only serve to entice to gluttony, and so work our ruin.

[Sidenote: _Sick, to recover soonest._]

Another saith, that the less food the sick person eats, the sooner he will recover; for it is a true saying, _the more you fill foul bodies, the more you hurt them_. The stomach being the place where diseases have their origin, when that part therefore is weak, and out of order, and cannot make a good digestion, if much is eaten, raw and crude humours must needs be bred, and bad humours cannot produce good blood.

[Sidenote: _The evil of full meals._]

All men find by experience, that, in the morning before they have eaten, they are light and pleasantly easy in their bodies; but, after they have indulged their appetites with plenty of food, they find themselves heavy and dull, and often sleepy: which sufficiently shews, that those full meals are prejudicial to the welfare of the body; for a moderate meal would have continued the ease and lightsomeness they before found in themselves, and would have refreshed any faintness that emptiness might occasion. And he certainly, who useth the most simple meats and drinks, avoideth the snare of provoking his appetite beyond the necessities of nature; whereas variety enticeth to a fresh desire of every dainty, till at last the stomach is gorged, and made uncapable of performing a good digestion; and this produceth those crudities which are the cause of all diseases, and of so many sudden deaths.

[Sidenote: _The evil of high feeding._]

It is generally observed, that the most unhealthy are found among those who feed high upon the most delicious dainties, and drink nothing but the strongest and most spirituous liquors; whereas others who want this delicate fare, are seldom sick, except they have such unsatiable appetites as to eat too much; which a man may do of the plainest diet, whose _belly is his god_, as an apostle expresses it. Phil. iii 19. But tho' men may glut themselves with coarse food, yet coarse food, and long life are very confident, as appears by John Bill, mentioned in the history of _Cold Baths_, p. 408. whose food was bread, cheese, and butter; and drink, whey, butter-milk, or water; and yet he lived 133 years, and was a strong, strait, upright man. And the food of John Bailes, whose age amounted to 128, was for the most part brown bread and cheese; and his drink, water, or small beer and milk, _Cold Bath_, p. 416. He had buried the whole town of Northampton twenty times over, except three or four, and said, _Strong drink killed them all_.

[Sidenote: _Small suppers best._]

Dr. Pratt adviseth to sup sparingly; for to sup sparingly, he saith, is most healthful, because of the experience of an infinite number of persons who have received the greatest benefit from light suppers. For the stomach being not overburdened, the sleep is more pleasant; and from sparing suppers the breeding of those humours it prevented, which cause defluxions, rheumatisms, gouts, dropsies, giddiness, and corruption in the mouth from the scurvy: And from light suppers a freedom from sickness and reaching in the morning is obtained, and concoction is made perfect, which prevents obstructions.

[Sidenote: _Fasting, its benefit._]

Another saith, it is well known, that many indispositions are cured by fasting, or a very spare diet; for what is taken into the stomach being no more than can be well digested, the chylous juice, so rightly prepared, is conveyed into the lacteal vessels, and from thence into the blood; so that, nature being duly supplied with well-concocted nourishment, the corrupted blood will free itself from that corruption in time, by throwing it out, through the pores of the skin, in perspiration, and supply itself with the purer juices; and, in this way, consumptions and scurvies, and other chronical distempers, will be overcome. Which way of curing diseases by fasting, swine do naturally betake themselves to, who, when sick, will eat nothing till they recover, as they always do after they injure themselves by over-eating; in which over-eating they are imitated by all who delight in gluttony, tho' not in using the same means of recovery, by fasting; so that hogs are wiser in that particular than such people.

[Sidenote: _A rule in eating._]

That men in health may prevent diseases, it was advised, that one meal should not be eaten, till the other, which was eaten before, was passed off clean out of the stomach; which never is done till the appetite of hunger is found to call for another supply: By means of which constant observation, the food will be converted to good chyle, and from good chyle, which is a milk-like substance, good blood will be bred, and from good blood generous spirits will be produced, on which a healthy constitution will ensue; but, on the contrary, when too great a quantity of food is taken for pleasure only, which the stomach cannot well digest, the chyle will be raw and corrupt, which will foul the blood, and render the body disordered and unhealthy.

[Sidenote: _Benefits of sobriety._]

Others say, that abstinence and sobriety free from most diseases, especially catarrhs, coughs, wheesings, giddiness, pain in the head and stomach, sudden death, lethargies, gout and sciatica, an ill digestion being the cause of all these; it also prevents pains in the splene, stone, and gravel, and a dry itch; it makes the body vigorous and nimble, maintains the five senses in a good state, preserveth the memory, quickens the wit; and quencheth all undue lust in mankind; and, in short, all misers, who eat and drink but little, do live long.

[Sidenote: _Rule for diet after fifty._]

Two meals a day is said to be sufficient for all persons after fifty years of age, and all weak people; and the omitting of suppers does always conduce much to the health of the weak and aged: since, if no supper be eaten, the stomach will soon free itself from all tough, slimy humours wherewith it is slabbered over on the inside, and thereby the appetite will be renewed, and digestion made more strong. Moreover, all that are troubled with sweating in the night, any ill taste in their mouths, belching and troublesome dreams, must avoid suppers; for in sleep the fibres of the stomach relax, and are not able to contract themselves so strongly, as when awake, to embrace the food, and by tituration reduce it into a pap fit to pass into the intestines, out of which the nourishment is sent to other parts.

[Sidenote: _Temperance prolongs life._]

It was said by Dr. Curtis, that tho' those who use a spare diet cannot well bear long labour; yet such people, when their exercise is suitable to their strength, do live longer than those of a robust constitution, that think large feeding adds strength; especially such as, being strong, use no exercise proportionable to it, to consume the superfluities which a full feeding doth occasion: So that the only way for those to live long, who have much wealth, and need not labour for a livelihood, is to live temperately; and this temperance doth consist in not letting the common custom of meals invite you to eat, except your appetite concur with those times. We must not indulge the cravings of a depraved appetite, as those do who eat to please their fancy, and not the necessities of nature; and, when we do eat, we must not think that the more plentifully we eat, we shall be the more strengthened; for it will not prove so: A little well digested will make the body stronger then the being glutted with superfluity, most of which will be turned into a corrupt juice, and must be cast out by physic, or else sickness will ensue. The easiest physic is that which the Germans call the _Hunger-cure_, if continued a due time.

[Sidenote: _Children, when ill managed._]

It is the opinion of learned men, that the early distemper of the bodies of children, called the rickets, proceeds from the faults of their mothers, in making them gluttons from their cradles, gorging them with food till they lothe it, out of a mistaken opinion, that this is the way to make them thrive and grow strong: which excess is not only the cause of this disease, but of the immature death of many; and in others it lays the foundation of many distempers, which afflict those afterwards who live to years of maturity. And as they gorge them with food, so they vainly think to cherish them with strong drink, than which nothing can be more pernicious to the health of children, whose diet should be little and often, and their drink cooling. As it also should be when men arrive at the time of becoming children again in old age, that is, in an helpless state, which should be prevented as much as can be, by a cooling, moistening diet, in opposition to the hot, dry, and withered state of age; for it is heat and dryness that are the cause of most old men's miseries, especially the wasting of the substance that fills the parts with moisture, and keeps the body plump and smooth; they who stile wine the old man's milk, being greatly mistaken, for milk cools and wine heats.

[Sidenote: _Rules for sickness._]

It was the opinion of Dr Pitt, who was formerly physician to St. Bartholomew's hospital, that fasting, rest, and drinking water, would cure most diseases. And there seemeth to be a great deal of reason in what he asserts: for fasting will give time to the stomach to unload itself of the cause of distempers, the cause of all diseases being begun in that bowel only: to which cleansing, the drinking of

water plentifully will much contribute; which also will keep the action of the stomach upon the hinges, by filling of it when empty, at which time there will be need of rest, for thereby the body will be less fit for business: Tho' the mere drinking of water, which affords nourishment sufficient for the growth and support of all vegetables, will, in some measure, supply the want of food; as hath been shewn in the example of two, who were supported a long time by nothing else. In short, the best way for a sick man to recover, is to eat little or no food till he finds an appetite, according to that saying,

Spare diet will the most diseases cure, If a due time the same you can endure.

And fasting from food may be continued long enough to be a remedy for many diseases, with the assistance of common water; by the drinking of which warm, in a due quantity, without a total fasting, two persons, I am informed, were recovered out of consumptions, with which they were extremely weakened, and that in about six weeks time; as another by drinking milk and whey, equal parts, made blood hot, without using any other diet, which is thought to be far more effectual than asses milk, whose virtue consists in being thinner than other milk.

[Sidenote: _Air, its benefit._]

But, besides a spare diet, cool dry air is also very helpful to preserve men in health, who are not sick; for it mixes with the blood, and without it the motion of the blood and spirits can never be preserved; as appears by diving vessels, in which men cannot live when the air therein is made hot by their own body and breath: And is proved also by an experiment of Dr. Croone's, who stifled a chicken till it seemed quite dead; and yet, by blowing cool air into the lungs with a small pair of bellows, it revived. Hence it appears, that the common custom of managing sick people is very pernicious, and so far from helping them to recover, that it is sufficient to make a healthy person sick: For were a person, who was not sick, confined for three or four weeks in a room made hot like a stove, and kept in his bed, with the curtains drawn, and all the windows close shut, and the room made unpleasant with the nauseous fumes of physic and a close-stool, which will almost make a healthy man sick when he enters into it; we can never think that this is the way to recover one that really is sick, and wants the fresh air and reviving scents to cherish his blood; a fresh, open, sweet air being one principal means to strengthen the body, make a good appetite and digestion, and render the spirits brisk and lively: which advantage should be allowed to all but childbed women, and those who are afflicted with the small pox: for the fresh air can be prejudicial to no other, whose bodies are clothed warm, either in bed, or sitting in a chair in their chamber.

[Sidenote: _A fever suddenly cured._]

Some years since, a neighbour became very feverish, and his wife persuaded him to go to bed; and hearing of it soon after, I gave him a visit where I found the windows close shut, the curtains of the bed drawn, and the room very hot, for it was in July: He was burning hot, and complained for want of breath. I drew open the curtains, covered him warm, and then opened the windows, and the wind blew into the room; upon which he soon told me, his shortness of breath had left him. I persuaded him to drink water, which he found did much refresh him; and, after I had taken my leave of him, he called for more water: and, while he had the cup in his hand, an apothecary came in, whom his wife had sent for, who, finding him about to drink the water, told him, if he did it, he was a dead man; but, instead of forbearing, he drank it up in his presence: upon which the other took his leave, and told him, he would say no more to him. However, before night, the person got up, went abroad, and was cured of his fever. Which is one instance, among many others that might be given, of the benefit of fresh air to a person who is kept warm in his bed; for thereby his body was cooled inwardly, and his breathing made more free, by the air which was drawn into his lungs to refresh and comfort the blood as it passed through them.

[Sidenote: _A cool and low diet._]

I shall only add, that by keeping the blood cool as well as clean, is to be understood, not only moderation in diet, but to feed most on cooling food made of wheat, barley, oat-meal, rice, and ripe apples, as also on milk, which, joined with oat-meal, is the chief food of those lusty and strong men, the Highlanders of Scotland, who abound in children, as Dr. Cheyne tells us in his _Treatise of the Gout_, p. 108. edit. 4. which demonstrates milk and oat-meal to be a most strengthening food, and such as keeps the blood in due order; so that therewith men may subsist, tho' they abstain from beef, pork and venison, and all other meats hard to digest, and drink water as the highlanders do: Of the efficacy of which cooling milk-diet the said Dr. Cheyne gives a notable instance in a doctor that lived at Croyden, p. 103. who had long been afflicted with the falling-evil; for, by slow observation, he found the lighter his meals were, the lighter were his fits. At last he also cast off all liquids but water, and found his fits weaker, and the intervals longer; and finding his disease mend, as its fewel was withdrawn, he took to vegetable food, and water only, which put an entire period to his fits without any relapse: But finding that food windy to him, he took to milk, of which he drank a pint for a breakfast, a quart at

dinner, and a pint for supper, without fish, flesh, bread, or any strong or spirituous liquor, or any drink but water, with which he lived afterwards for fourteen years, without the least interruption in his health, strength or vigour, but died afterwards of a pleurisy. Which is a confirmation of what Dr. Cook did affirm, of the possibility of curing diseases by a diet only, that is temperate and cooling; of which milk is a part, as are also the roots and seeds of vegetables, such as potatoes, turnips, wheat, rice, barley, oat-meal, and full ripe fruit.

In short, temperance or a spare diet, void of dainties, never was injurious to the strongest constitution; and, without it, such as are weak and sickly cannot long subsist; for the more such persons eat and drink, the more weak and disordered they will still find themselves to be: so that if the strong despise temperance, yet the comfort of weak, sickly and pining people, does depend entirely upon their constantly observing it; which, when they are accustomed to it, will be easy to do: So that they will deny all intemperate desires with as great pleasure, as they before delighted in what is falsely stiled good eating and drinking; for nothing of that is good, which is injurious to health. It is custom only that makes men hanker after gluttony and drunkenness, and a contrary custom will make men abhor it as much: And therefore it is a wonder the rich do not strive to attain to it; for

A fatal error 'tis in men of wealth, To feed so high as will destroy their health.

Temperance being that which will enable them to live most at ease, and enjoy their wealth the longest; this, and water-drinking, being the surest way to bring men to old age, tho' it hath not power to make those young who are aged, yet it will make the aged more free from decripedness, and die with most ease, if the deathbed hath been well prepared for by a good life.

ENFRANCHISEMENT OF WOMEN:

BY MRS. JOHN STUART MILL.

REPRINTED FROM THE

"WESTMINSTER AND FOREIGN QUARTERLY REVIEW,"

FOR JULY, 1851.

Most of our readers will probably learn from these pages, for the first time, that there has arisen in the United States, and in the most civilized and enlightened portion of them, an organized agitation on a new question,--new, not to thinkers, nor to any one by whom the principles of free and popular government are felt, as well as acknowledged, but new, and even unheard of, as a subject for public meetings and practical political action. This question is, the enfranchisement of women; their admission, in law, and in fact, to equality in all rights, political, civil and social, with the male citizens of the community.

It will add to the surprise with which many will receive this intelligence, that the agitation which has commenced is not a pleading by male writers and orators _for_ women, those who are professedly to be benefited remaining either indifferent or ostensibly hostile; it is a political movement, practical in its objects, carried on in a form which denotes an intention to persevere. And it is a movement not merely _for_ women, but _by_ them. Its first public manifestation appears to have been a convention of women, held in the State of New York, July, 1848. Of this meeting we have seen no report. On the 23d and 24th of October last, a succession of public meetings was held at Worcester, in Massachusetts, under the name of a "Women's Rights Convention," of which the president was a woman, and nearly all the chief speakers women; numerously reinforced, however, by men, among whom were some of the most distinguished leaders in the kindred cause of negro emancipation. A general and four special committees were nominated, for the purpose of carrying on the undertaking until the next annual meeting.

According to the report in the _New York Tribune_, above a thousand persons were present throughout, and, "if a larger place could have been had, many thousands more would have attended." The place was described as "crowded, from the beginning, with attentive and interested listeners." In regard to the quality of the speaking, the proceedings bear an advantageous comparison with those of any popular movement with which we are acquainted, either in this country or in America. Very rarely, in the oratory of public meetings, is the part of verbiage and declamation so small, that of calm good sense and reason so considerable. The result of the convention was, in every respect, encouraging to those by whom it was summoned; and it is probably destined to inaugurate one of the most important of the movements towards political and social reform, which are the best characteristic of the present age.

That the promoters of this new agitation take their stand on principles, and do not fear to declare these in their widest extent, without time-serving or compromise, will be seen from the resolutions adopted by the convention, part of which we transcribe:

Resolved, That every human being, of full age, and resident for a proper length of time on the soil of the nation, who is required to obey the law, is entitled to a voice in its enactment; that every such person, whose property or labor is taxed for the support of the government, is entitled to a direct share in such government. Therefore,

Resolved, That women are entitled to the right of suffrage, and to be considered eligible to office; and that every party, which claims to represent the humanity, the civilization, and the progress of the age, is bound to inscribe on its banners, equality before the law, without distinction of sex or color.

Resolved, That civil and political rights acknowledge no sex, and therefore the word "male" should be stricken from every state constitution.

Resolved, That, since the prospect of honorable and useful employment in after life is the best stimulus to the use of educational advantages, and since the best education is that we give ourselves, in the struggles, employments and discipline of life; therefore it is impossible that women should make full use of the instruction already accorded to them, or that their career should do justice to their faculties, until the avenues to the various civil and professional employments are thrown open to them.

Resolved, That every effort to educate women, without according to them their rights, and arousing their conscience by the weight of their responsibilities, is futile, and a waste of labor.

Resolved, That the laws of property, as affecting married persons, demand a thorough revisal, so that all rights be equal between them; that the wife have, during life, an equal control over the property gained by their mutual toil and sacrifices, and be heir to her husband precisely to that extent that he is heir to her, and entitled at her death to dispose by will of the same share of the joint property as he is.

The following is a brief summary of the principal demands:

1. _Education_ in primary and high schools, universities, medical, legal and theological institutions.

2. _Partnership_ in the labors and gains, risks and remunerations, of productive industry.

3. _A coëqual share_ in the formation and administration of laws,--municipal, state and national,--through legislative assemblies, courts, and executive offices.

It would be difficult to put so much true, just and reasonable meaning into a style so little calculated to recommend it as that of some of the resolutions. But whatever objection may be made to some of the expressions, none, in our opinion, can be made to the demands themselves. As a question of justice, the case seems to us too clear for dispute. As one of expediency, the more thoroughly it is examined, the stronger it will appear.

That women have as good a claim as men have, in point of personal right, to the suffrage, or to a place in the jury-box, it would be difficult for anyone to deny. It cannot certainly be denied by the United States of America, as a people or as a community. Their democratic institutions rest avowedly on the inherent right of every one to a voice in the government. Their Declaration of Independence, framed by the men who are still their great constitutional authorities,--that document which has been from the first, and is now, the acknowledged basis of their polity,--commences with this express statement:

"We hold these truths to be self-evident: that all men are created equal; that they are endowed by their Creator with certain inalienable rights; that among these are life, liberty, and the pursuit of happiness; that, to secure these rights, governments are instituted among men, deriving their just powers from the consent of the governed."

We do not imagine that any American democrat will evade the force of these expressions by the dishonest or ignorant subterfuge, that "men," in this memorable document, does not stand for human beings, but for one sex only; that "life, liberty and the pursuit of happiness," are "inalienable rights" of only one moiety of the human species; and that "the governed," whose consent is affirmed to be the only source of just power, are meant for that half of mankind only, who, in relation to the other, have hitherto assumed the character of _governors_. The contradiction between principle and practice cannot be explained away. A like dereliction of the fundamental maxims of their political creed has been committed by the Americans in the flagrant instance of the negroes; of this they are learning to recognize the turpitude. After a struggle which, by many of its incidents, deserves the name of heroic, the abolitionists are now so strong in numbers and influence, that they hold the balance of parties in the United States. It was fitting that the men whose names will remain associated with the extirpation from the democratic soil of America of the aristocracy of color, should be among the originators, for America and for the rest of the world, of the first collective protest against the aristocracy of sex; a distinction as accidental as that of color, and fully as irrelevant to all questions of government.

Not only to the democracy of America the claim of women to civil and political equality makes an irresistible appeal, but also to those radicals and chartists in the British islands, and democrats on the continent, who claim what is called universal suffrage as an inherent right, unjustly and oppressively withheld from them. For with what truth or rationality could the suffrage be termed universal, while half the human species remain excluded from it? To declare that a voice in the government is the right of all, and demand it only for a part,--the part, namely, to which the claimant himself belongs,--is to renounce even the appearance of principle. The chartist who denies the suffrage to women is a chartist only because he is not a lord; he is one of those levellers who would level only down to themselves.

Even those who do not look upon a voice in the government as a matter of personal right, nor profess principles which require that it should be extended to all, have usually traditional maxims of political justice, with which it is impossible to reconcile the exclusion of all women from the common rights of citizenship. It is an axiom of English freedom, that taxation and representation should be coëxtensive. Even under the laws which give the wife's property to the husband, there are many unmarried women who pay taxes. It is one of the fundamental doctrines of the British constitution, that all persons should be tried by their peers; yet women, whenever tried, are tried by male judges and a male jury. To foreigners, the law accords the privilege of claiming that half the jury should be composed of themselves; not so to women. Apart from maxims of detail, which represent local and national, rather than universal ideas, it is an acknowledged dictate of justice, to make no degrading distinctions without necessity. In all things, the presumption ought to be on the side of equality. A reason must be given why anything should be permitted to one person, and interdicted to another. But when that which is interdicted includes nearly everything which those to whom it is permitted most prize, and to be deprived of which they feel to be most insulting; when not only political liberty, but personal freedom of action, is the prerogative of a caste; when even, in the exercise of industry, almost all employments which task the higher faculties in an important field, which lead to distinction, riches, or even pecuniary independence, are fenced round as the exclusive domain of the predominant section, scarcely any doors being left open to the dependent class, except such as all who can enter elsewhere disdainfully pass by; the miserable expediencies which are advanced as excuses for so grossly partial a dispensation would not be sufficient, even if they were real, to render it other than a flagrant injustice. While, far from being expedient, we are firmly convinced that the division of mankind into two castes, one born to rule over the other, is, in this case, as in all cases, an unqualified mischief; a source of perversion and demoralization, both to the favored class and to those at whose expense they are favored; producing none of the good which it is the custom to ascribe to it, and forming a bar, almost insuperable, while it lasts, to any really vital improvement, either in the character or in the social condition of the human race.

These propositions it is now our purpose to maintain. But, before entering on them, we would endeavor to dispel the preliminary objections which, in the minds of persons to whom the subject is new, are apt to prevent a real and conscientious examination of it. The chief of these obstacles is that most formidable one--custom. Women never have had equal rights with men. The claim in their behalf, of the common rights of mankind, is looked upon as barred by universal practice. This strongest of prejudices, the prejudice against what is new and unknown, has, indeed, in an age of changes like the present, lost much of its force; if it had not, there would be little hope of prevailing against it. Over three fourths of the habitable world, even at this day, the answer, "It has always been so," closes all discussion. But it is the boast of modern Europeans, and of their American kindred, that they know and do many things which their forefathers neither knew nor did; and it is, perhaps, the most unquestionable point of superiority in the

present, above former ages, that habit is not now the tyrant it formerly was over opinions and modes of action, and that the worship of custom is a declining idolatry. An uncustomary thought, on a subject which touches the greater interests of life, still startles when first presented; but if it can be kept before the mind until the impression of strangeness wears off, it obtains a hearing, and as rational a consideration as the intellect of the hearer is accustomed to bestow on any other subject.

In the present case, the prejudice of custom is doubtless on the unjust side. Great thinkers, indeed, at different times, from Plato to Condorcet, besides some of the most eminent names of the present age, have made emphatic protests in favor of the equality of women. And there have been voluntary societies, religious or secular, of which the Society of Friends is the most known, by whom that principle was recognized. But there has been no political community or nation in which, by law, and usage, women have not been in a state of political and civil inferiority. In the ancient world, the same fact was alleged, with equal truth, in behalf of slavery. It might have been alleged in favor of the mitigated form of slavery, serfdom, all through the middle ages. It was urged against freedom of industry, freedom of conscience, freedom of the press; none of these liberties were thought compatible with a well-ordered state, until they had proved their possibility by actually existing as facts. That an institution or a practice is customary, is no presumption of its goodness, when any other sufficient cause can be assigned for its existence. There is no difficulty in understanding why the subjection of women has been a custom. No other explanation is needed than physical force.

That those who were physically weaker should have been made legally inferior, is quite conformable to the mode in which the world has been governed. Until very lately, the rule of physical strength was the general law of human affairs. Throughout history, the nations, races, classes, which found themselves the strongest, either in muscles, in riches, or in military discipline, have conquered and held in subjection the rest. If, even in the most improved nations, the law of the sword is at last discountenanced as unworthy, it is only since the calumniated eighteenth century. Wars of conquest have only ceased since democratic revolutions began. The world is very young, and has but just begun to cast off injustice. It is only now getting rid of negro slavery. It is only now getting rid of monarchical despotism. It is only now getting rid of hereditary feudal nobility. It is only now getting rid of disabilities on the ground of religion. It is only beginning to treat any _men_ as citizens, except the rich and a favored portion of the middle class. Can we wonder that it has not yet done as much for women? As society was constituted until the last few generations, inequality was its very basis; association grounded on equal rights scarcely existed; to be equals was to be enemies; two persons could hardly coöperate in anything, or meet in any amicable relation, without the law's appointing that one of them should be the superior of the other. Mankind have outgrown this state, and all things now tend to substitute, as the general principle of human relations, a just equality instead of the dominion of the strongest. But, of all relations, that between men and women being the nearest and most intimate, and connected with the greatest number of strong emotions, was sure to be the last to throw off the old rule and receive the new; for, in proportion to the strength of a feeling, is the tenacity with which it clings to the forms and circumstances with which it has even accidentally become associated.

When a prejudice which has any hold on the feelings finds itself reduced to the unpleasant necessity of assigning reasons, it thinks it has done enough when it has reässerted the very point in dispute, in phrases which appeal to the preëxisting feeling. Thus, many persons think they have sufficiently justified the restrictions on women's field of action when they have said that the pursuits from which women are excluded are _unfeminine_, and that the _proper sphere_ of women is not politics or publicity, but private and domestic life.

We deny the right of any portion of the species to decide for another portion, or any individual for another individual, what is and what is not their "proper sphere." The proper sphere for all human beings is the largest and highest which they are able to attain to. What this is, cannot be ascertained without complete liberty of choice. The speakers at the convention in America have, therefore, done wisely and right in refusing to entertain the question of the peculiar aptitudes either of women or of men, or the limits within which this or that occupation may be supposed to be more adapted to the one or to the other. They justly maintain that these questions can only be satisfactorily answered by perfect freedom. Let every occupation be open to all, without favor or discouragement to any, and employments will fall into the hands of those men or women who are found by experience to be most capable of worthily exercising them. There need be no fear that women will take out of the hands of men any occupation which men perform better than they. Each individual will prove his or her capacities, in the only way in which capacities can be proved, by trial; and the world will have the benefit of the best faculties of all its inhabitants. But to interfere beforehand by an arbitrary limit, and declare that whatever be the genius, talent, energy, or force of mind, of an individual of a certain sex or class, those faculties shall not be exerted, or shall be exerted only in some few of the many modes in which others are permitted to use theirs, is not only an injustice to the individual, and a detriment to society, which loses what it can ill spare, but is also the most effectual mode of providing that, in the sex or class so fettered, the qualities which are not permitted to be exercised shall not exist.

We shall follow the very proper example of the convention, in not entering into the question of the alleged differences in physical or mental qualities between the sexes; not because we have nothing to say, but because we have too much: to discuss this one point tolerably would need all the space we have to bestow on the entire subject[1]. But if those who assert that the "proper sphere" for women is the domestic mean by this that they have not shown themselves qualified for any other, the assertion evinces great ignorance of life and of history. Women have shown fitness for the highest social functions exactly in proportion as they have been admitted to them. By a curious anomaly, though ineligible to even the lowest offices of state, they are in some countries admitted to the highest of all, the regal; and if there is any one function for which they have shown a decided vocation, it is that of reigning. Not to go back to ancient history, we look in vain for abler or firmer rulers than Elizabeth; than Isabella of Castile; than Maria Theresa; than Catharine of Russia; than Blanche, mother of Louis IX. of France; than Jeanne d'Albret, mother of Henri Quatre. There are few kings on record who contended with more difficult circumstances, or overcame them more triumphantly, than these. Even in semi-barbarous Asia, princesses who have never been seen by men other than those of their own family, or ever spoken with them unless from behind a curtain, have, as regents, during the minority of their sons, exhibited many of the most brilliant examples of just and vigorous administration. In the middle ages, when the distance between the upper and lower ranks was greater than even between women and men, and the women of the privileged class, however subject to tyranny from men of the same class, were at a less distance below them than any one else was, and often in their absence represented them in their functions and authority, numbers of heroic chatelaines, like Jeanne de Montfort, or the great Countess of Derby, as late even as the time of Charles I., distinguished themselves, not only by their political, but their military capacity. In the centuries immediately before and after the Reformation, ladies of royal houses, as diplomatists, as governors of provinces, or as the confidential advisers of kings, equalled the first statesmen of their time; and the treaty of Cambray, which gave peace to Europe, was negotiated, in conferences where no other person was present, by the aunt of the Emperor Charles the Fifth, and the mother of Francis the First.

[1] An excellent passage on this part of the subject, from one of Sydney Smith's contributions to the _Edinburgh Review_, we will not refrain from quoting: "A great deal has been said of the original difference of capacity between men and women as if women were more quick and men more judicious; as if women were more remarkable for delicacy of association, and men for stronger powers of attention. All this, we confess, appears to us very fanciful. That there is a difference in the understandings of the men and the women we every day meet with, everybody, we suppose, must perceive; but there is none, surely, which may not be accounted for by the difference of circumstances in which they have been placed, without referring to any conjectural difference of original conformation of mind. As long as boys and girls run about in the dirt, and trundle hoops together, they are both precisely alike. If you catch up one half of these creatures, and train them to a particular set of actions and opinions, and the other half to a perfectly opposite set, of course their understandings will differ, as one or the other sort of occupations has called this or that talent into action. There is surely no occasion to go into any deeper or more abstruse reasoning, in order to explain so very simple a phenomenon."--_Sydney Smith's Works_, vol. i., p. 200.

Concerning the fitness, then, of women for politics, there can be no question: but the dispute is more likely to turn upon the fitness of politics for women. When the reasons alleged for excluding women from active life in all its higher departments are stripped of their garb of declamatory phrases, and reduced to the simple expression of a meaning, they seem to be mainly three: the incompatibility of active life with maternity, and with the cares of a household; secondly, its alleged hardening effect on the character; and, thirdly, the inexpediency of making an addition to the already excessive pressure of competition in every kind of professional or lucrative employment.

The first, the maternity argument, is usually laid most stress upon; although (it needs hardly be said) this reason, if it be one, can apply only to mothers. It is neither necessary nor just to make imperative on women that they shall be either mothers or nothing; or, that if they had been mothers once, they shall be nothing else during the whole remainder of their lives. Neither women nor men need any law to exclude them from an occupation, if they have undertaken another which is incompatible with it. No one proposes to exclude the male sex from parliament because a man may be a soldier or sailor in active service, or a merchant whose business requires all his time and energies. Nine tenths of the occupations of men exclude them _de facto_ from public life, as effectually as if they were excluded by law; but that is no reason for making laws to exclude even the nine tenths, much less the remaining tenth. The reason of the case is the same for women as for men. There is no need to make provision by law that a woman shall not carry on the active details of a household, or of the education of children, and at the same time practise a profession or be elected to parliament. Where incompatibility is real, it will take care of itself; but there is gross injustice in making the incompatibility a pretence for the exclusion of those in whose case it does not exist. And these, if they were free to choose, would be a very large proportion. The maternity argument deserts its supporters in the case of single women, a large and increasing class of the population--a fact which, it is not irrelevant to remark, by tending to diminish the excessive competition of numbers, is calculated to assist greatly the

prosperity of all. There is no inherent reason or necessity that all women should voluntarily choose to devote their lives to one animal function and its consequences. Numbers of women are wives and mothers only because there is no other career open to them, no other occupation for their feelings or their activities. Every improvement in their education and enlargement of their faculties, everything which renders them more qualified for any other mode of life, increases the number of those to whom it is an injury and an oppression to be denied the choice. To say that women must be excluded from active life because maternity disqualifies them for it, is in fact to say that every other career should be forbidden them, in order that maternity may be their only resource.

But, secondly, it is urged, that to give the same freedom of occupation to women as to men, would be an injurious addition to the crowd of competitors, by whom the avenues to almost all kinds of employment are choked up, and its remuneration depressed. This argument, it is to be observed, does not reach the political question. It gives no excuse for withholding from women the rights of citizenship. The suffrage, the jury-box, admission to the legislature and to office, it does not touch. It bears only on the industrial branch of the subject. Allowing it, then, in an economical point of view, its full force,--assuming that to lay open to women the employments now monopolized by men would tend, like the breaking down of other monopolies, to lower the rate of remuneration in those employments,--let us consider what is the amount of this evil consequence, and what the compensation for it. The worst ever asserted, much worse than is at all likely to be realized, is, that if women competed with men, a man and a woman could not together earn more than is now earned by the man alone. Let us make this supposition, the most unfavorable supposition possible: the joint income of the two would be the same as before, while the woman would be raised from the position of a servant to that of a partner. Even if every woman, as matters now stand, had a claim on some man for support, how infinitely preferable is it that part of the income should be of the woman's earning, even if the aggregate sum were but little increased by it, rather than that she should be compelled to stand aside in order that men may be the sole earners, and the sole dispensers of what is earned! Even under the present laws respecting the property of women,[2] a woman who contributes materially to the support of the family cannot be treated in the same contemptuously tyrannical manner as one who, however she may toil as a domestic drudge, is a dependent on the man for subsistence. As for the depression of wages by increase of competition, remedies will be found for it in time. Palliatives might be applied immediately; for instance, a more rigid exclusion of children from industrial employment, during the years in which they ought to be working only to strengthen their bodies and minds for after life. Children are necessarily dependent, and under the power of others; and their labor, being not for themselves, but for the gain of their parents, is a proper subject for legislative regulation. With respect to the future, we neither believe that improvident multiplication, and the consequent excessive difficulty of gaining a subsistence, will always continue, nor that the division of mankind into capitalists and hired laborers, and the regulation of the reward of laborers mainly by demand and supply, will be forever, or even much longer, the rule of the world. But so long as competition is the general law of human life, it is tyranny to shut out one half of the competitors. All who have attained the age of self-government have an equal claim to be permitted to sell whatever kind of useful labor they are capable of, for the price which it will bring.

[2] The truly horrible effects of the present state of the law among the lowest of the working population is exhibited in those cases of hideous mal-treatment of their wives by working men, with which every newspaper, every police report, teems. Wretches unfit to have the smallest authority over any living thing have a helpless woman for their household slave. These excesses could not exist if women both earned and had the right to possess a part of the income of the family.

The third objection to the admission of women to political or professional life, its alleged hardening tendency, belongs to an age now past, and is scarcely to be comprehended by people of the present time. There are still, however, persons who say that the world and its avocations render men selfish and unfeeling; that the struggles, rivalries and collisions of business and of politics, make them harsh and unamiable; that if half the species must unavoidably be given up to these things, it is the more necessary that the other half should be kept free from them; that to preserve women from the bad influences of the world is the only chance of preventing men from being wholly given up to them.

There would have been plausibility in this argument when the world was still in the age of violence; when life was full of physical conflict, and every man had to redress his injuries, or those of others, by the sword or by the strength of his arm. Women, like priests, by being exempted from such responsibilities, and from some part of the accompanying dangers, may have been enabled to exercise a beneficial influence. But in the present condition of human life, we do not know where those hardening influences are to be found, to which men are subject, and from which women are at present exempt. Individuals now-a-days are seldom called upon to fight hand to hand, even with peaceful weapons; personal enmities and rivalries count for little in worldly transactions; the general pressure of circumstances, not the adverse will of individuals, is the obstacle men now have to make head against. That

pressure, when excessive, breaks the spirit, and cramps and sours the feelings, but not less of women than of men, since they suffer certainly not less from its evils. There are still quarrels and dislikes, but the sources of them are changed. The feudal chief once found his bitterest enemy in his powerful neighbor, the minister or courtier in his rival for place; but opposition of interest in active life, as a cause of personal animosity, is out of date; the enmities of the present day arise not from great things, but small,--from what people say of one another, more than from what they do; and if there are hatred, malice, and all uncharitableness, they are to be found among women fully as much as among men. In the present state of civilization, the notion of guarding women from the hardening influences of the world could only be realized by secluding them from society altogether. The common duties of common life, as at present constituted, are incompatible with any other softness in women than weakness. Surely weak minds in weak bodies must ere long cease to be even supposed to be either attractive or amiable.

But, in truth, none of these arguments and considerations touch the foundations of the subject. The real question is, whether it is right and expedient that one half of the human race should pass through life in a state of forced subordination to the other half. If the best state of human society is that of being divided into two parts, one consisting of persons with a will and a substantive existence, the other of humble companions to these persons, attached each of them to one, for the purpose of bringing up _his_ children, and making _his_ home pleasant to him; if this is the place assigned to women, it is but kindness to educate them for this; to make them believe that the greatest good fortune which can befall them is to be chosen by some man for this purpose; and that every other career which the world deems happy or honorable is closed to them by the law, not of social institutions, but of nature and destiny.

When, however, we ask, why the existence of one half the species should be merely ancillary to that of the other,--why each woman should be a mere appendage to a man, allowed to have no interests of her own, that there may be nothing to compete in her mind with his interests and his pleasure,--the only reason which can be given is, that men like it. It is agreeable to them that men should live for their own sake, women for the sake of men; and the qualities and conduct in subjects which are agreeable to rulers they succeed for a long time in making the subjects themselves consider as their appropriate virtues. Helvetius has met with much obloquy for asserting that persons usually mean by virtues the qualities which are useful or convenient to themselves. How truly this is said of mankind in general, and how wonderfully the ideas of virtue, set afloat by the powerful, are caught and imbibed by those under their dominion, is exemplified by the manner in which the world were once persuaded that the supreme virtue of subjects was loyalty to kings, and are still persuaded that the paramount virtue of womanhood is loyalty to men. Under a nominal recognition of a moral code common to both, in practice self-will and self-assertion form the type of what are designated as manly virtues, while abnegation of self, patience, resignation, and submission to power, unless when resistance is commanded by other interests than their own, have been stamped by general consent as preëminently the duties and graces required of women. The meaning being, merely, that power makes itself the centre of moral obligation, and that a man likes to have his own will, but does not like that his domestic companion should have a will different from his.

We are far from pretending that in modern and civilized times no reciprocity of obligation is acknowledged on the part of the stronger. Such an assertion would be very wide of the truth. But even this reciprocity, which has disarmed tyranny, at least in the higher and middle classes, of its most revolting features, yet when combined with the original evil of the dependent condition of women, has introduced in its turn serious evils.

In the beginning, and among tribes which are still in a primitive condition, women were and are the slaves of men for the purposes of toil. All the hard bodily labor devolves on them. The Australian savage is idle, while women painfully dig up the roots on which he lives. An American Indian, when he has killed a deer, leaves it, and sends a woman to carry it home. In a state somewhat more advanced, as in Asia, women were and are the slaves of men for the purposes of sensuality. In Europe, there early succeeded a third and milder dominion, secured not by blows, nor by locks and bars, but by sedulous inculcation on the mind; feelings also of kindness, and ideas of duty, such as a superior owes to inferiors under his protection, became more and more involved in the relation. But it did not, for many ages, become a relation of companionship, even between unequals; the lives of the two persons were apart. The wife was part of the furniture of home, of the resting-place to which the man returned from business or pleasure. His occupations were, as they still are, among men; his pleasures and excitements also were, for the most part, among men--among his equals. He was a patriarch and a despot within four walls, and irresponsible power had its effect, greater or less according to his disposition, in rendering him domineering, exacting, self-worshipping, when not capriciously or brutally tyrannical. But if the moral part of his nature suffered, it was not necessarily so, in the same degree, with the intellectual or the active portion. He might have as much vigor of mind and energy of character as his nature enabled him, and as the circumstances of his times allowed. He might write the "Paradise Lost," or win the battle of Marengo. This was the condition of the Greeks and Romans, and of

the moderns until a recent date. Their relations with their domestic subordinates occupied a mere corner, though a cherished one, of their lives. Their education as men, the formation of their character and faculties, depended mainly on a different class of influences.

It is otherwise now. The progress of improvement has imposed on all possessors of power, and of domestic power among the rest, an increased and increasing sense of correlative obligation. No man now thinks that his wife has no claim upon his actions, but such as he may accord to her. All men, of any conscience, believe that their duty to their wives is one of the most binding of their obligations. Nor is it supposed to consist solely in protection, which, in the present state of civilization, women have almost ceased to need; it involves care for their happiness and consideration of their wishes, with a not unfrequent sacrifice of their own to them. The power of husbands has reached the stage which the power of kings had arrived at, when opinion did not yet question the rightfulness of arbitrary power, but in theory, and to a certain extent in practice, condemned the selfish use of it. This improvement in the moral sentiments of mankind, and increased sense of the consideration due by every man to those who have no one but himself to look to, has tended to make home more and more the centre of interest, and domestic circumstances and society a larger and larger part of life, and of its pursuits and pleasures. The tendency has been strengthened by the changes of tastes and manners which have so remarkably distinguished the last two or three generations. In days not far distant, men found their excitement and filled up their time in violent bodily exercises, noisy merriment, and intemperance. They have now, in all but the very poorest classes, lost their inclination for these things, and for the coarser pleasures generally; they have now scarcely any tastes but those which they have in common with women, and, for the first time in the world, men and women are really companions. A most beneficial change, if the companionship were between equals; but being between unequals, it produces, what good observers have noticed, though without perceiving its cause, a progressive deterioration among men in what had hitherto been considered the masculine excellences. Those who are so careful that women should not become men, do not see that men are becoming what they have decided that women should be--are falling into the feebleness which they have so long cultivated in their companions. Those who are associated in their lives tend to become assimilated in character. In the present closeness of association between the sexes, men cannot retain manliness unless women acquire it.

There is hardly any situation more unfavorable to the maintenance of elevation of character or force of intellect, than to live in the society, and seek by preference the sympathy, of inferiors in mental endowments. Why is it that we constantly see in life so much of intellectual and moral promise followed by such inadequate performance, but because the aspirant has compared himself only with those below himself, and has not sought improvement or stimulus from measuring himself with his equals or superiors? In the present state of social life, this is becoming the general condition of men. They care less and less for any sympathies, and are less and less under any personal influences, but those of the domestic roof. Not to be misunderstood, it is necessary that we should distinctly disclaim the belief that women are even now inferior in intellect to men. There are women who are the equals in intellect of any men who ever lived; and, comparing ordinary women with ordinary men, the varied though petty details which compose the occupation of women call forth probably as much of mental ability as the uniform routine of the pursuits which are the habitual occupation of a large majority of men. It is from nothing in the faculties themselves, but from the petty subjects and interests on which alone they are exercised, that the companionship of women, such as their present circumstances make them, so often exercises a dissolvent influence on high faculties and aspirations in men. If one of the two has no knowledge and no care about the great ideas and purposes which dignify life, or about any of its practical concerns save personal interests and personal vanities, her conscious, and still more her unconscious influence, will, except in rare cases, reduce to a secondary place in his mind, if not entirely extinguish, those interests which she cannot or does not share. Our argument here brings us into collision with what may be termed the moderate reformers of the education of women; a sort of persons who cross the path of improvement on all great questions; those who would maintain the old bad principles, mitigating their consequences. These say, that women should be, not slaves nor servants, but companions, and educated for that office (they do not say that men should be educated to be the companions of women). But since uncultivated women are not suitable companions for cultivated men, and a man who feels interest in things above and beyond the family circle wishes that his companion should sympathize with him in that interest, they therefore say, let women improve their understanding and taste, acquire general knowledge, cultivate poetry, art, even coquet with science, and some stretch their liberality so far as to say, inform themselves on politics; not as pursuits, but sufficiently to feel an interest in the subjects, and to be capable of holding a conversation on them with the husband, or at least of understanding and imbibing his wisdom. Very agreeable to him, no doubt, but unfortunately the reverse of improving. It is from having intellectual communion only with those to whom they can lay down the law, that so few men continue to advance in wisdom beyond the first stages. The most eminent men cease to improve if they associate only with disciples. When they have overtopped those who immediately surround them, if they wish for further growth, they must seek for others of their own stature to consort with. The

mental companionship which is improving is communion between active minds, not mere contact between an active mind and a passive. This inestimable advantage is even now enjoyed when a strong-minded man and a strong-minded woman are, by a rare chance, united; and would be had far oftener, if education took the same pains to form strong-minded women which it takes to prevent them from being formed. The modern, and what are regarded as the improved and enlightened modes of education of women, abjure, as far as words go, an education of mere show, and profess to aim at solid instruction, but mean by that expression superficial information on solid subjects. Except accomplishments, which are now generally regarded as to be taught well, if taught at all, nothing is taught to women thoroughly. Small portions only of what it is attempted to teach thoroughly to boys are the whole of what it is intended or desired to teach to women. What makes intelligent beings is the power of thought; the stimuli which call forth that power are the interest and dignity of thought itself, and a field for its practical application. Both motives are cut off from those who are told from infancy that thought, and all its greater applications, are other people's business, while theirs is to make themselves agreeable to other people. High mental powers in women will be but an exceptional accident, until every career is open to them, and until they, as well as men, are educated for themselves and for the world,--not one sex for the other.

In what we have said on the effect of the inferior position of women, combined with the present constitution of married life, we have thus far had in view only the most favorable cases, those in which there is some real approach to that union and blending of characters and of lives which the theory of the relation contemplates as its ideal standard. But if we look to the great majority of cases, the effect of women's legal inferiority on the character both of women and of men must be painted in far darker colors. We do not speak here of the grosser brutalities, nor of the man's power to seize on the woman's earnings, or compel her to live with him against her will. We do not address ourselves to any one who requires to have it proved that these things should be remedied. We suppose average cases, in which there is neither complete union nor complete disunion of feelings and of character; and we affirm that in such cases the influence of the dependence on the woman's side is demoralizing to the character of both.

The common opinion is, that, whatever may be the case with the intellectual, the moral influence of women over men is almost always salutary. It is, we are often told, the great counteractive of selfishness. However the case may be as to personal influence, the influence of the position tends eminently to promote selfishness. The most insignificant of men, the man who can obtain influence or consideration nowhere else, finds one place where he is chief and head. There is one person, often greatly his superior in understanding, who is obliged to consult him, and whom he is not obliged to consult. He is judge, magistrate, ruler, over their joint concerns; arbiter of all differences between them. The justice or conscience to which her appeal must be made is his justice and conscience; it is his to hold the balance and adjust the scales between his own claims or wishes and those of another. He is now the only tribunal, in civilized life, in which the same person is judge and party. A generous mind, in such a situation, makes the balance incline against its own side, and gives the other not less, but more than a fair equality; and thus the weaker side may be enabled to turn the very fact of dependence into an instrument of power, and, in default of justice, take an ungenerous advantage of generosity; rendering the unjust power, to those who make an unselfish use of it, a torment and a burthen. But how is it when average men are invested with this power, without reciprocity and without responsibility? Give such a man the idea that he is first in law and in opinion,--that to will is his part, and hers to submit; it is absurd to suppose that this idea merely glides over his mind, without sinking into it, or having any effect on his feelings and practice. The propensity to make himself the first object of consideration, and others at most the second, is not so rare as to be wanting where everything seems purposely arranged for permitting its indulgence. If there is any self-will in the man, he becomes either the conscious or unconscious despot of his household. The wife, indeed, often succeeds in gaining her objects, but it is by some of the many various forms of indirectness and management.

Thus the position is corrupting equally to both; in the one it produces the vices of power, in the other those of artifice. Women, in their present physical and moral state, having stronger impulses, would naturally be franker and more direct than men; yet all the old saws and traditions represent them as artful and dissembling. Why? Because their only way to their objects is by indirect paths. In all countries where women have strong wishes and active minds, this consequence is inevitable; and if it is less conspicuous in England than in some other places, it is because English women, saving occasional exceptions, have ceased to have either strong wishes or active minds.

We are not now speaking of cases in which there is anything deserving the name of strong affection on both sides. That, where it exists, is too powerful a principle not to modify greatly the bad influences of the situation; it seldom, however, destroys them entirely. Much oftener the bad influences are too strong for the affection, and destroy it. The highest order of durable and happy attachments would be a hundred times more frequent than they are, if the affection which the two sexes sought from one another were that genuine friendship which only exists between equals in privileges as in faculties. But with regard to what is commonly

called affection in married life,--the habitual and almost mechanical feeling of kindliness and pleasure in each other's society, which generally grows up between persons who constantly live together, unless there is actual dislike,--there is nothing in this to contradict or qualify the mischievous influence of the unequal relation. Such feelings often exist between a sultan and his favorites, between a master and his servants; they are merely examples of the pliability of human nature, which accommodates itself, in some degree, even to the worst circumstances, and the commonest nature always the most easily.

With respect to the influence personally exercised by women over men, it, no doubt, renders them less harsh and brutal; in ruder times, it was often the only softening influence to which they were accessible. But the assertion that the wife's influence renders the man less selfish contains, as things now are, fully as much error as truth. Selfishness towards the wife herself, and towards those in whom she is interested, the children, though favored by their dependence, the wife's influence no doubt tends to counteract. But the general effect on him of her character, so long as her interests are concentrated in the family, tends but to substitute for individual selfishness a family selfishness, wearing an amiable guise, and putting on the mask of duty. How rarely is the wife's influence on the side of public virtue! how rarely does it do otherwise than discourage any effort of principle by which the private interests or worldly vanities of the family can be expected to suffer! Public spirit, sense of duty towards the public good, is, of all virtues, as women are now educated and situated, the most rarely to be found among them; they have seldom even, what in men is often a partial substitute for public spirit, a sense of personal honor connected with any public duty. Many a man, whom no money or personal flattery would have bought, has bartered his political opinions against a title or invitations for his wife; and a still greater number are made mere hunters after the puerile vanities of society, because their wives value them. As for opinions, in Catholic countries, the wife's influence is another name for that of the priest; he gives her, in the hopes and emotions connected with a future life, a consolation for the sufferings and disappointments which are her ordinary lot in this. Elsewhere, her weight is thrown into the scale either of the most commonplace, or of the most outwardly prosperous opinions, either those by which censure will be escaped, or by which worldly advancement is likeliest to be procured. In England the wife's influence is usually on the illiberal and anti-popular side; this is generally the gaining side for personal interest and vanity; and what to her is the democracy or liberalism in which she has no part--which leaves her the Pariah it found her? The man himself, when he marries, usually declines into conservatism; begins to sympathize with the holders of power more than with the victims, and thinks it his part to be on the side of authority. As to mental progress, except those vulgarer attainments by which vanity or ambition are promoted, there is generally an end to it in a man who marries a woman mentally his inferior; unless, indeed, he is unhappy in marriage, or becomes indifferent. From a man of twenty-five or thirty, after he is married, an experienced observer seldom expects any further progress in mind or feelings. It is rare that the progress already made is maintained. Any spark of the _mens divinior_, which might otherwise have spread and become a flame, seldom survives for any length of time unextinguished. For a mind which learns to be satisfied with what it already is, which does not incessantly look forward to a degree of improvement not yet reached, becomes relaxed, self-indulgent, and loses the spring and tension which maintain it even at the point already attained. And there is no fact in human nature to which experience bears more invariable testimony than to this; that all social or sympathetic influences which do not raise up pull down; if they do not tend to stimulate and exalt the mind, they tend to vulgarize it.

For the interest, therefore, not only of women, but of men, and of human improvement, in the widest sense, the emancipation of women, which the modern world often boasts of having effected, and for which credit is sometimes given to civilization, and sometimes to Christianity, cannot stop where it is. If it were either necessary or just that one portion of mankind should remain mentally and spiritually only half developed, the development of the other portion ought to have been made, as far as possible, independent of their influence. Instead of this, they have become the most intimate, and, it may now be said, the only intimate associates of those to whom yet they are sedulously kept inferior; and have been raised just high enough to drag the others down to themselves.

We have left behind a host of vulgar objections, either as not worthy of an answer, or as answered by the general course of our remarks. A few words, however, must be said on one plea, which, in England, is made much use of, for giving an unselfish air to the upholding of selfish privileges, and which, with unobserving, unreflecting people, passes for much more than it is worth. Women, it is said, do not desire, do not seek, what is called their emancipation. On the contrary, they generally disown such claims when made in their behalf, and fall with _acharnement_ upon any one of themselves who identifies herself with their common cause.

Supposing the fact to be true in the fullest extent ever asserted, if it proves that European women ought to remain as they are, it proves exactly the same with respect to Asiatic women; for they, too, instead of murmuring at their seclusion, and at the restraint imposed upon them, pride themselves on it, and are astonished at the effrontery of women who receive visits from male

acquaintances, and are seen in the streets unveiled. Habits of submission make men, as well as women, servile-minded. The vast population of Asia do not desire or value--probably would not accept--political liberty, nor the savages of the forest civilization; which does not prove that either of those things is undesirable for them, or that they will not, at some future time, enjoy it. Custom hardens human beings to any kind of degradation, by deadening the part of their nature which would resist it. And the case of women is, in this respect, even, a peculiar one, for no other inferior caste that we have heard of have been taught to regard their degradation as their honor. The argument, however, implies a secret consciousness that the alleged preference of women for their dependent state is merely apparent, and arises from their being allowed no choice; for, if the preference be natural, there can be no necessity for enforcing it by law. To make laws compelling people to follow their inclination, has not hitherto been thought necessary by any legislator. The plea that women do not desire any change is the same that has been urged, times out of mind, against the proposal of abolishing any social evil,--"there is no complaint;" which is generally not true, and, when true, only so because there is not that hope of success, without which complaint seldom makes itself audible to unwilling ears. How does the objector know that women do not desire equality and freedom? He never knew a woman who did not, or would not, desire it for herself individually. It would be very simple to suppose that, if they do desire it, they will say so. Their position is like that of the tenants or laborers who vote against their own political interests to please their landlords or employers; with the unique addition that submission is inculcated on them from childhood, as the peculiar attraction and grace of their character. They are taught to think that, to repel actively even an admitted injustice, done to themselves, is somewhat unfeminine, and had better be left to some male friend or protector. To be accused of rebelling against anything which admits of being called an ordinance of society, they are taught to regard as an imputation of a serious offence, to say the least, against the proprieties of their sex. It requires unusual moral courage, as well as disinterestedness, in a woman, to express opinions favorable to women's enfranchisement, until, at least, there is some prospect of obtaining it. The comfort of her individual life, and her social consideration, usually depend on the good will of those who hold the undue power; and to possessors of power any complaint, however bitter, of the misuse of it, is a less flagrant act of insubordination than to protest against the power itself. The professions of women in this matter remind us of the state offenders of old, who, on the point of execution, used to protest their love and devotion to the sovereign by whose unjust mandate they suffered. Griselda herself might be matched from the speeches put by Shakspeare into the mouths of male victims of kingly caprice and tyranny; the Duke of Buckingham, for example, in "Henry the Eighth," and even Wolsey. The literary class of women, especially in England, are ostentatious in disclaiming the desire for equality of citizenship, and proclaiming their complete satisfaction with the place which society assigns to them; exercising in this, as in many other respects, a most noxious influence over the feelings and opinions of men, who unsuspectingly accept the servilities of toadyism as concessions to the force of truth, not considering that it is the personal interest of these women to profess whatever opinions they expect will be agreeable to men. It is not among men of talent, sprung from the people, and patronized and flattered by the aristocracy, that we look for the leaders of a democratic movement. Successful literary women are just as unlikely to prefer the cause of women to their own social consideration. They depend on men's opinion for their literary as well as for their feminine successes; and such is their bad opinion of men, that they believe that there is not more than one in ten thousand who does not dislike and fear strength, sincerity, or high spirit, in a woman. They are, therefore, anxious to earn pardon and toleration, for whatever of these qualities their writings may exhibit on other subjects, by a studied display of submission on this: that they may give no occasion for vulgar men to say--what nothing will prevent vulgar men from saying--that learning makes women unfeminine, and that literary ladies are likely to be bad wives.

WOMAN

SUFFRAGE ASSOCIATION

OF MISSOURI.

MRS. FRANCIS MINOR, _President_. MRS. BEVERLY ALLEN, _Vice-President_. MRS. WM. T. HAZARD, _Corresponding Secretary_. MRS. GEO. D. HALL, _Recording Secretary_. MRS. NATHAN STEVENS, _Treasurer_.

St. Louis, Missouri.

To the General Assembly of the State of Missouri:

GENTLEMEN:

The undersigned men and women of Missouri, believing that all citizens who are taxed for the support of the Government and subject to its laws, should have a voice in the making of those laws, and the selection of their rulers; that, as the possession of the ballot ennobles and elevates the character of man, so, in like manner, it would ennoble and elevate that of woman, by giving her a direct and personal interest in the affairs of Government; and, further, believing that the spirit of the age, as well as every consideration of justice and equity, require that the ballot should be extended to woman, do unite in praying that an amendment to the Constitution may be proposed, striking out the word "male," and extending to women the right of suffrage.

And, as in duty bound, your petitioners will ever pray.

Copies of Petition, and Information furnished upon addressing either of above named officers.

Formation of Auxiliary Associations in every county requested. Petitions when completely signed to be returned to the head office.

FOREWORD

The purpose of this book is to tell in simple language “Something About Sugar.” It gives a brief history of the commodity and its production in different parts of the world, and seeks to show, for the information, especially, of the layman and the pupil in school, the various steps by which sugar from cane and beets is prepared for the consumer.

Growth, Manufacture and Distribution

WHAT SUGAR IS

Among the many varieties of sugar the most important are the sucroses and the glucoses. They form a natural group of substances, chiefly of vegetable origin. Chemically considered, all sugars are carbohydrates, that is to say, bodies composed of three elements: carbon, hydrogen and oxygen. Sucrose contains twelve atoms of carbon, twenty-two atoms of hydrogen and eleven atoms of oxygen.

Apart from sucrose, which is usually cane and beet sugar, the variety most generally met with is dextrose—one of the glucoses. It possesses less sweetness than sucrose and differs from the latter in chemical composition. As an example: dextrose is found in the raisin in small grains. It also occurs in other fruits and is the result of the inversion of sucrose.

Glucose enters largely into the manufacture of candy, being particularly necessary in the preparation of soft filling for creams, as a certain amount of it added to cane-sugar syrup prevents crystallization.

Sucrose is derived from sugar cane, maple sap, sorghum and the sugar beet. It is a solid, crystallizing in the form of monoclinic prisms, generally with hemihedral faces, which are colorless, transparent, have a sweet taste, a specific gravity of 1.6 and a melting point of about 320 degrees Fahrenheit. It is soluble in about one-half its weight in cold water, and in boiling water in almost all proportions. It is practically insoluble in alcohol, turpentine, ether, chloroform and similar fluids.

The crop of 1914-15 showed a world's production of 18,409,016 long tons of sugar, and in the chapters relating to the history of sugar will be found a statement setting forth the amount produced by each country. The total was derived about one-half from cane and one-half from beets, produced as follows:

CANE BEET Total in America 5,017,375 660,236 " Asia 4,268,618 " Australia and Polynesia 348,408 " Africa 523,788 " Europe 7,376[4] 7,583,215 ---------- --------- 10,165,565 8,243,451

Sugar cane, described in botany as _Saccharum officinarum_, is a giant-stemmed perennial grass that grows from eight to twenty-four feet long. When ripe it produces at the top of its stalk a large feathery plume of flowers of a gray inflorescence called the "tassel," which is from two to four feet in length.

There are many kinds of cane, all of which are regarded as varieties of one species, although some botanists have raised a few to the rank of distinct species. The cultivated types are distinguished by the color of the internodes, yellow, red, purple or striped, and by other general characteristics.

[Illustration: SUGAR CANE—SHOWING EYES OR BUDS]

The stem of the cane is solid, with joints at intervals of three to six inches. In diameter it ranges from one to two and a half inches, and is unbranched, bearing in its upper part numerous long, narrow grass-like leaves, arranged in two rows. The leaves spring from large sheaths around the joints, and have a more or less spreading blade from three to five feet in length and two inches or more in width. The pith, of open cellular structure, contains the sugary juice. The tops, which contain but little sugar, are not crushed, but are used for seed, as the plant germinates from the eyes, or buds, which grow on the stem around the joints. Practically no cultivated cane is propagated from its seed. The roots that remain in the ground after the cane is harvested throw up fresh canes or ratoons for many seasons, after which replanting is necessary. Hawaiian growers do not count on ratoons for more than a few crops, whereas in Cuba this process can be repeated for many years.

As a rule, sugar cane consists of about eighty-eight per cent of juice and twelve per cent of fiber, the juice content varying from time to time, both as regards quality and amount. The quantity of the juice pressed from the cane determines the efficiency of the extraction, while quality is the main factor when the result of subsequent manufacture is under analysis.

It is difficult to arrive at a fair average of the composition of the juice of the cane, as it varies in different countries, on different plantations in the same country, and at different periods in any one year. The following is an approximation:

Water 80.8 per cent Sugar 16.4 " Invert sugar 1.98 " Organic non-sugar .54 " Ash (mineral matter) .28 "

THE GROWING OF SUGAR CANE

Sugar cane grows almost exclusively in the tropical belt, extending from twenty-two degrees north to twenty-two degrees south latitude, where the three essentials for its successful culture, viz., fertile soil, hot sunshine and plenty of moisture, are present. It flourishes in the islands of the Pacific ocean, particularly in the Hawaiian group, in Cuba, Mexico, Central America, the islands of the East and West Indies, Australia, China, India, along the shores of the China sea and the Indian ocean, and in certain parts of Africa and South America. In the low latitudes of the temperate zone it is grown with only fair success.

Owing to peculiar climatic conditions, sugar cane has been raised in southern Spain for generations, notwithstanding the fact that the provinces in which the sugar cane is grown lie, roughly speaking, between thirty-six degrees and thirty-eight degrees north latitude. The Gulf Stream is no doubt largely responsible for this phenomenon. The quantity of sugar produced in Spain, however, is small, the crop of 1914-15 amounting to less than 8000 tons.

Sugar cane thrives best in a moist, warm climate, with moderate intervals of dry, hot weather, and plenty of water for irrigation. It requires marly soil, free from saline ingredients. As a rule, it is raised on the lowlands, where the temperature is highest and where it is easy to bring water for irrigation. In Hawaii it takes eighteen months to ripen, and “tasseling” occurs about thirty days before it is ready to be cut. In Louisiana and Texas, because of the short seasons, cane is harvested in from nine to ten months from the time of sprouting, and, consequently, before it has attained maturity. In Cuba it is cut in twelve months, whether it is ripe or not.

[Illustration: ROOTS OF SUGAR CANE]

[Illustration: JUNGLE-LIKE VEGETATION OF CANE FIELD]

As the scientific culture and manufacture of sugar is probably further advanced in the Hawaiian islands than in any other part of the world, a description of the industry as carried on there will serve to illustrate the intensive cultivation and scientific methods of the present day.

The Hawaiian islands are situated in the Pacific ocean, in latitude nineteen degrees to twenty-two degrees north and in longitude one hundred and fifty-four degrees to one hundred and sixty-one degrees west, and are free from the destructive hurricanes of the East and West Indies. They are of volcanic formation and, as a rule, their centers are mountainous, in some instances reaching an elevation of nearly fourteen thousand feet. During the ages, torrential rains carried volcanic ash from the mountains toward the sea, near which it was deposited, thus forming alluvial areas of vast richness around the circumference of the islands. Parts of some of the islands are fringed with coral reefs, barriers that retain the washings from the mountains. In these low-lying areas the soil is extraordinarily fertile, and it is on such ground that the most generous crops are raised.

The soft, warm trade winds that blow from the northeast become laden with moisture as they sweep over the ocean; when they strike the cold mountain peaks the moisture condenses immediately into copious rains. The precipitation in some places reaches the astounding total of three hundred inches per annum. The rain water is conserved and, when needed, is carried to the various plantations by immense irrigation ditches.

In this tropical region there is an abundance of sunshine, accompanied by humid heat, exactly the conditions needed. It required only man’s ingenuity to utilize what nature so lavishly provided.

The commercial cultivation of sugar cane in these islands began about 1850, when a few hundred tons of raw sugar were produced, but the methods of husbandry and manufacture were crude. Time and experience worked great changes, until in 1914-15 the crop of raw sugar totaled 646,448 tons of 2000 pounds each.

For many years past the sugar planters have maintained in Honolulu an experimental station that is the marvel of the agricultural world. The bulletins issued by it are recognized as authoritative, and are read with interest in every sugar-producing country.

The most important features of the work carried on at this station are:

1. SOIL ANALYSIS

Skilled chemists examine the soils of the various plantations and, when occasion demands, advise the planter what necessary element is lacking, as well as how to obtain and apply it. A few years ago this branch of the work was considered highly important. Recently, however, the agriculturists have been depending more upon well-defined systems of experimentation. Each plantation has on its own lands plots of ground on which different methods of culture are tried and on which various kinds of fertilizer are used. Experiments are also made to determine the exact amount of water needed for irrigation. Particular attention is paid to seed cane, and a number of types of it are planted in order to obtain seed that will produce stalks that grow rapidly, yield a large tonnage per acre, contain a maximum amount of sugar, and have a high resistant power against disease and insect pests. The success attending this practical experimental work is such that soil analysis is being relegated to second place.

2. ENTOMOLOGY

A staff of trained experts assiduously study the insect life and eagerly watch for harmful, troublesome pests, which in the past have wrought great damage. It is their duty to find the means of eliminating these pests, and this they usually accomplish through the skillful use of insect parasites.

3. PATHOLOGY

The pathologists attached to the station supplement the scientific labors of the chemists and the entomologists by prescribing for any disease that may attack the cane. Plant life is subject to as many ills as the human family, and the work of these specialists in restoring health to ailing cane is of the highest importance.

To fully illustrate the character and scope of their work, a particular instance for each department may be cited:

A certain planter found that the amount of sugar obtained from his cane was decreasing yearly, though he could see no good reason for it. The land looked right; he ploughed deeply, harrowed well, kept the weeds down, gave the cane plenty of water, could find no reason to complain of climatic conditions, but still did not get satisfactory results. Finally the head of the experimental station was consulted and an agricultural chemist was sent to the plantation. This chemist, after careful investigation, took samples of the soil from various parts of the land; these were analyzed and the source of the trouble was found to be the lack of potash. Just here it may be explained that when the same crop is taken from the land many years in succession, without adequate fertilization, some of the essential properties of the soil become exhausted. Speaking generally, these are lime, soda, potash, phosphates and nitrogen. In this particular instance, as has been said, the land had been gradually drained of its potash. The experimental station recommended the planter to scatter a certain fertilizer over his fields. This advice was followed and the next crop showed remarkable improvement, the yield of cane and sugar per acre being greater than ever before.

At one time the sugar industry of the Hawaiian islands was threatened with annihilation by a little insect called the “leaf-hopper.” The harm done by this pest was so enormous that one plantation having an average yearly crop of 19,000 tons was so severely affected that the yield dropped from 19,000 to 12,000, and then to 3000 tons in three successive crops. All the plantations on the islands suffered to a greater or lesser extent, and the entire sugar industry of Hawaii was jeopardized.

The hoppers punctured the stalks and leaves of the young cane, and in the holes thus formed laid their eggs by thousands. When the young hoppers hatched out, they fed on the juices in the stalk and in the leaves, thus destroying the leaves and depriving the cane of its protection and principal means of absorbing nourishment from the air.

As soon as the leaf-hopper by its ravages made itself known in the islands, the entomologists were consulted, and they were confronted with the task of studying the life and habits of the hopper for the purpose of finding, if possible, some other insects that would attack and exterminate it. It is well known to entomologists that every insect pest has natural enemies; the vital question in this case was—what were the natural enemies of the leaf-hopper and where were they to be found? Obviously, too, the problem was to discover insectivorous enemies that would not themselves attack the cane after they had destroyed the hopper.

After careful investigation it was concluded that the leaf-hopper had been introduced in Hawaii in new varieties of seed cane imported from Australia, and, as the hopper was not doing material damage on the plantations in Australia, the inference was that it must be controlled there by its natural enemy. The chief of the Department of Entomology was sent to London. There in the archives of the British Museum he found a full description of the leaf-hopper and that its native habitat was Queensland, Australia. On his return to Hawaii, entomologists were sent to Australia and the search for the enemy of the hopper began.

[Illustration: LEAF-HOPPER (GREATLY MAGNIFIED)]

[Illustration: SUGAR CANE]

For weeks the entomologists virtually lived in the cane fields, undergoing extreme privations, but at last their faithfulness was crowned with success. Several species of parasites that kept the Queensland leaf-hopper in check were discovered, and later on more were found in the islands of Fiji. These tiny creatures as a rule were invisible to the naked eye and could only be seen with the aid of a powerful magnifying glass. All of these insects were parasites either of the leaf-hopper or its eggs. Two of them were particularly efficacious. One, quicker in movement than the hopper, caught it unawares and attached itself to the hopper’s body much in the same way that a mosquito does to a human being. After catching it, the parasite would sting the hopper and lay an egg in its body. In a few days a young parasite was hatched from the egg, and so ravenous was this young insect that it devoured the hopper in a short time and then sought a fresh victim in which to lay its eggs.

The other insect was even more effective. It liked the hoppers’ eggs and for a long time found plenty in Hawaii to stay its appetite. As soon as the leaf-hopper laid its eggs in the cane, this particular insect would appear and lay its eggs in the eggs of the leaf-hopper. When the little enemies hatched out, they fed on the hoppers’ eggs and in turn laid their eggs in the eggs of the hopper. It came to pass that the hoppers, attacked by the parasite on the one hand and by the enemy on the other, rapidly dwindled in number until only a few remained, and these not enough to do material damage. As the hoppers and their eggs diminished, so

did the parasite and the enemy, for the latter could live on insect food only.

How the scientists collected these tiny animalcules, kept them alive, transported them thousands of miles across the ocean, bred them in Hawaii and saved the Hawaiian sugar industry, reads like a romance.

The study of entomology is extremely interesting and the every-day business man rarely understands its importance. The finding, breeding and distribution of parasites of insect pests vitally affects the world's food supply. The entomological name of the leaf-hopper family is _Hemiptera_, and Dr. Sharp, an authority on the subject, has said: "There is probably no order of insects that is so directly connected with the welfare of the human race as the hemiptera; indeed if anything were to exterminate the enemies of hemiptera, we ourselves should probably be starved in the course of a few months."

It has been estimated by competent authority that the damage done in the world each year by the hemiptera, in spite of all their parasites, is conservatively $600,000,000. Were it not for the parasites, it would only be a year or two at most before every green leaf and spear of grass would disappear from the face of the earth. The direct influence of the practical application of this science to the production of sugar is readily apparent.

Pathology is almost equally important. In former years when cane failed to grow strong and sturdy and did not yield much sugar, the planter usually attributed the difficulty either to lack of water, poor soil, cool weather, too much rain or insufficient cultivation of the field by his manager, when in fact the trouble was due to none of these causes. He would personally oversee the operations of the following year, but with no better results.

[Illustration: EXPERIMENT STATION]

[Illustration: PLANTATION SCENE IN HAWAII—LIGHT-COLORED FOLIAGE IS SUGAR CANE]

When the roots of the cane became matted, stuck together and turned black, when a thick gum exuded from the stalk and leaves, preventing the plant from drawing proper nourishment from the air, it was thought that these troubles arose from climatic or local conditions, while in reality the plant was sick and needed a doctor. Today, under the new régime, whenever the plant shows any symptoms of ill-health, the pathologists are called in to eradicate the disease by scientific treatment.

Insect pests and plant diseases are generally brought into a country through planters sending to other cane-raising countries for new varieties of cane for seeding purposes that they think may produce more sugar than their own. Great trouble and heavy loss have been occasioned in this way and, as a consequence, the United States government has established a strict quarantine, allowing plant life to be landed only after rigid examination and when it is clear that no danger exists.

Another example of the work of the entomologists may be of interest:

During the visit of a well-known Hawaiian to Mexico many years ago, his attention was attracted by a beautiful shrub that he thought would make a splendid hedge around his home. It grew about five feet in height and its foliage was of a rich green, with a brown, red and yellow flower. The slips he brought to Honolulu thrived wonderfully and cuttings of the plant were taken to the other islands for a like purpose. Wherever planted it grew amazingly fast. It quickly spread over the hillsides and became so dense that cattle could not penetrate the thickets formed by it. It made valueless large areas of land that formerly had been used for the pasturing of cattle and plantation stock, and reduced the grazing area at an alarming rate. Land that adjoined the plantations and that in the course of time became needed for plantation purposes was also over-run by it.

The curtailment of the grazing lands and the increased cost of clearing were so great that the entomologists were finally sent for and asked if they could not eradicate the trouble. After a careful investigation they went to Mexico, whence the lantana, as the shrub is called, had come. On their return journey they brought back with them a fly. The fly laid its eggs in the bud of the lantana, and when the young flies were hatched they fed upon the lantana seeds. The flies multiplied rapidly and soon made away with the seeds, thus preventing the shrub from spreading any further. When it was once cleared from the land or the plantation it did not reappear.

These illustrations demonstrate the fact that the culture of sugar cane involves a constant struggle between science and unrestrained nature.

As a rule, Hawaiian sugar plantations are located close to the seacoast, between it and the base of the mountains. The lands slope gently toward the sea, thus insuring good drainage and easy application of water for irrigation. Most of the cane is grown on land

less than five hundred feet above sea-level, although in a few rare instances it is cultivated at an elevation as great as three thousand feet. Parts of the leeward side of the islands, where it is extremely dry and hot, and where the cane thrives best, depend entirely on irrigation, the water being brought to the plantations by ditches or pumped from wells. On the windward side of the island of Hawaii, where the rainfall is abundant, irrigation is unnecessary except during very dry periods.

In cultivating, the ground is turned with steam ploughs to depths up to twenty-four inches. These ploughs are operated by powerful engines that work in pairs, one on each side of a field, usually from one thousand to fifteen hundred feet apart. One engine pulls a gang-plough across the field and the other draws it back. By this method the rich soil is thoroughly loosened and a wonderful vegetable growth results. Ordinarily in California the farmer ploughs only from four to six inches deep.

[Illustration: STEAM PLOUGH]

[Illustration: PLANTING CANE]

After the lands are ploughed and harrowed and all the weeds turned under, double mould-board ploughs are used to make the furrows in which the seed is planted. The furrows are not like those made for planting potatoes, but are about five feet apart and eighteen inches deep, each furrow and hill being symmetrical. They follow the contour of the land so that the irrigation water will fill the furrow and remain there until it is absorbed by the soil and penetrates to the cane roots. At regular intervals of about thirty-five feet, lateral ditches are cut, from which there is an entrance into every furrow. These lateral ditches deliver the water from the main ditches to the various parts of the fields. The land is now ready for the seed.

Meanwhile, the harvesting of the ripened cane in other fields is going on. As the laborers cut the cane, they top it, that is to say, they cut off about twelve inches of the upper part of the solid stalk. Sugar cane resembles bamboo, in that it is cylindrical in shape and divided every few inches into sections by rings or joints. In every joint there is a bud or eye, from which a shoot of cane will sprout, if properly planted in the ground and watered.

These tops, always cut from untasseled cane, contain very little sugar. They are carried to the newly prepared field and placed in rows in the furrows, end to end, lengthwise, the ends overlapping a trifle in order to guard against blank spaces in the growing cane. They are then covered, according to the season, with one to one and a half inches of earth, and the water is turned in until the furrow contains from three to four inches of water. Between six and ten days afterward, the little green cane shoots appear above the ground. From this time forward continuous irrigation and cultivation, together with proper fertilization, are required until the cane matures.

Planting usually begins in March and continues until September, sometimes later, and the cane ripens one year from the following December.

Growing cane should be watered every seven days, and the amount of water used for this purpose is enormous. For example: a plantation producing thirty-five thousand tons of sugar per annum needs twice as much water per day as the city of San Francisco.

The appearance of growing cane is much like that of Indian corn. The whole field area is covered with a dense, jungle-like vegetation of brilliant green. The leaves are long and narrow and hang in graceful curves. The cane grows so thick that it is almost impossible to crawl through it, and so seldom do the sun’s rays penetrate to the ground that rapid evaporation of the irrigation water cannot take place, hence the cane gets the full benefit of the moisture.

In certain varieties of cane, the great weight of the juice in the stalks causes them to bend, droop and take fantastic shapes. Sometimes they lie on the ground with the ends turned upward, and in fields where the stalks grow to a length of twenty-four feet, the average height of the tops above the ground is not over twelve feet. In other kinds the stalks stand straight up to a height of from eight to fourteen feet.

The production of cane per acre varies in different countries and in different parts of the same country, according to the character of the soil, climatic conditions, care and attention, use of fertilizer and amount of rainfall or irrigation. In Hawaii it ranges from twenty to eighty-five tons, and the amount of sugar obtained per acre runs from two and one-half tons to twelve tons, the average being about five tons.

Broadly speaking, lack of a normal amount of cane per acre, lack of sugar in the cane, or the prevalence of disease, is primarily due to an unsanitary or unsuitable condition of the soil. This can usually be corrected by proper cultural methods, such as adequate aeration of the soil, the turning under of the cane tops and leaves, application of lime and suitable combinations of fertilizing

ingredients. Fundamentally, cane requires a well-aerated, moist, alkaline soil and a fertilizer in which the nitrogen content is high and in excess of the potash and phosphoric acid. It is found that nitrate of soda, when applied alone or in combination with potash and phosphoric acid, produces a very strong growth. The proper sanitation of the soil tends to promote the beneficial bacterial action so essential to the growth of the cane.

[Illustration: IRRIGATION DITCH—SHOWING TUNNEL]

[Illustration: IRRIGATION DITCH]

In December and January the cane tassels or flowers, which indicates that it has about reached maturity and is ready for cutting. Thenceforward very little irrigating is done, as additional water applied at this time might retard ripening, which would mean a reduced amount of sugar stored up in the cane.

It is interesting to note that while the cane is growing and in an unripe state, there is no discernible sucrose or pure sugar in it. As the ripening process goes on, the content of the cane juice is changed by the action of the sun's rays, and the amount of sucrose as determined by polariscopic test shows when the time for harvesting is at hand. Nature's operation in thus changing glucose or invert sugar into sucrose or pure sugar cannot be accomplished by any human means.

The harvesting then begins and continues until the end of July or August. Usually the field is set on fire before cutting. On account of the great amount of moisture or juice in the cane, the stalks do not burn, but the leaves are thoroughly consumed. This operation eliminates a good deal of leaf material that is not only useless, but which, if sent to the mill, would increase the cost of crushing, besides absorbing a certain quantity of the juice expressed from the cane.

Formerly men stripped the leaves from the cane in the fields, but it was a difficult matter to accomplish such work, and the cost was heavy. An accident changed the method of doing this work. A field took fire and it was found that while all the leaves were consumed, little or no damage was done to the stalks provided they were cut promptly and sent to the mill to be crushed. The practice of burning has since become general, although the advisability of continuing it is now being given very careful study.

Burning eliminates the arduous labor of stripping, and no doubt does away with many harmful insects and fungi, but at the same time it destroys the enemies and parasites of these insects and this loss is severely felt. Another disadvantage of burning is that the nitrogen contained in the cane leaves is liberated and not returned to the soil as would be the case if the leaves were stripped and ploughed under. In the latter case the leaves rot rapidly, add humus to the soil, help aeration, and improve the sanitary condition, all of which tends to increase the yield of cane per acre. From recent experience it is not improbable that burning will be discontinued in the near future.

As soon as the field is ready, whether burned or not, the laborers go in to cut the cane. A long, heavy knife is used. The cutter grasps the stalk and drives the knife into it, severing it just at the ground. He then tops it, that is, he cuts off the upper part that contains no sugar, and, to aid in subsequent handling, the long stalks are cut into convenient lengths.

As the burning destroys the eyes or buds, certain fields are cut and topped for seed before the burning takes place.

There are two general methods of transporting the cane to the mills. One is by rail and the other by flumes. On the irrigated plantations where water is never overplentiful, railroad tracks and locomotives are invariably employed, while on the non-irrigated plantations, located in districts where there are copious annual rains, V-shaped flumes are extensively used. In some cases a combination of both systems is adopted to advantage. From the upper lands where it is difficult to construct railroads, the cane is flumed to a convenient point on the railroad system, at a lower elevation, and delivered into cars, while the water is conducted into ditches and used for irrigating the lower cane lands.

[Illustration: YOUNG SUGAR CANE]

[Illustration: RIPE SUGAR CANE—SHOWING TASSELS]

In the case of rail transportation, paths one hundred and fifty feet apart are cut through the fields so that temporary railroad tracks may be laid and cars run in and loaded on these tracks. The whole field is then cut in the same way and the work continued until the entire crop is harvested.

The loaders follow up the cutters. These men lay a strap on the ground and pile the stalks on the strap until they have a bundle of cane weighing from seventy-five to one hundred pounds. With a dexterity born of long practice, they sling a bundle upon their

shoulders and carry it up an inclined runway to a railroad car not over seventy-five feet away and dump it on the car. The cutting and loading are usually done by contract, at so much per ton, and it is remarkable how proficient the men become.

When flumes are used exclusively, much the same methods are adopted. Paths are cut through the fields and in these paths are placed the flumes which, like the temporary railroad tracks, are moved from time to time as necessity demands. The mill is located at the lowest point on the plantation and the flumes are placed so as to insure a good grade from the cane fields on the uplands to the mill below. The flumes are either carried on low trestles or run along the ground, but always at a height which enables the laborers to throw the cane into them conveniently.

Water is turned into the upper end of the flume and, rushing rapidly down, carries or floats the cane to the mill. Cane is flumed in this way for distances up to seven miles at low cost and with satisfactory results.

The cars when loaded in the fields are made up into trains and hauled by locomotives to the mill, which is generally located about the center of the plantation, or at a point where most of the cane can be delivered on a downward grade. Each car is carefully weighed on a track scale and the exact quantity of its load of cane is ascertained and recorded.

For years past the planters have been offering large rewards for the invention of a machine to cut and load the cane, but the old hand method is still employed, although some experimental loading machines are meeting with more or less success, but none are in common use.

The problems involved in cutting cane by machinery seem insurmountable, and, while many devices have been tried, not one has proved successful.

After the cane is cut the first time, ploughs are sent through the fields and a furrow is ploughed along each side of the stubs of the cane which are left in place. This ploughing opens up the ground, aerates the soil, and affords the irrigating or rain water a means of easy access to the cane roots. The water tenders follow up the ploughs and the furrows are filled with water, which is gradually absorbed by the old cane roots left in the ground. In time new sprouts spring up from buds on the old stalks of the cane and another growth begins. The second crop is called “first ratoons” and, when cultivated for a single year only, it is designated “short ratoons.” As a rule it does not yield as much sugar as plant cane, but the saving in seed, in the preparation of the fields and in other labor frequently makes up for the reduced amount of sugar. If allowed to grow for two years, as is generally the case, it is called “long ratoons” and produces proportionately more sugar. In the past a very large percentage of the Hawaiian crop was planted with fresh seed every year and but a small percentage ratooned. Nowadays, however, the tendency is to ratoon the crop as long as the yield justifies, which in many cases is from three to four times. In Cuba the cane when once planted is ratooned for many years.

There have been specific instances in Hawaii where ratoons that have been allowed to grow for two years (long ratoons) have shown a better yield than the first planting. According to the best information, this is due to the presence of poisonous matter in the ground, turned up for the first time at the first planting.

[Illustration: CUTTING CANE]

[Illustration: LOADING CANE]

The object of all the ploughing, weeding, cultivating, fertilizing and irrigating, is to produce a large number of strong, sturdy stalks of cane, yielding a maximum amount of sugar. The sugar is contained in solution in the sap or juice and the amount can be materially increased by due care and attention.

As some of the elements which form the plant are absorbed from the air through the leaves, favorable climatic conditions are essential to its full growth and development. Proper fertilizers must be added to the soil, and water applied regularly and in sufficient quantity.

Commercial fertilizers are used in Hawaii probably to a greater extent than in any other country in the world. It is quite common for plantations to use half a ton of fertilizer per acre per crop, and at times as much as two thousand pounds per acre. The yearly fertilizer cost per acre will probably average twenty-five dollars.

As it takes eighteen months for a crop to mature in Hawaii, it will readily be seen that the plantation area must be at least double that used for any one crop. While one crop is being harvested, another crop is in the ground growing. As soon as the cane is cut, the lands are immediately prepared for replanting or ratooning, as the case may be. During certain periods each year, usually in

June and July, a visitor on an Hawaiian plantation can see one crop growing, one being harvested and one being planted.

From the foregoing it will be seen that the harvesting begins in December and ends in July or August. The planting begins from March to June and usually ends in September, according to plantation conditions and whether or not the land is irrigated.

THE MANUFACTURE OF RAW SUGAR

The details of the manufacture of raw sugar from cane and of sugar from beet roots differ, but there are several processes common to both. The operations necessary for making raw cane sugar are as follows:

1. The extraction of the juice. 2. The purification of the juice. 3. The evaporation of the juice to syrup point. 4. The concentration and crystallization of the syrup. 5. The preparation of the crystals or grains for the market by separating them from the molasses.

Every mill has an extensive laboratory where skilled chemists are constantly engaged in sampling and analyzing cane, raw juices, syrups, sugars and molasses. In fact the chemical work is a most important feature in the raw-sugar house, beet-sugar factory or refinery. The superintendent should be an expert chemist, as the proper recovery of the sugar from the cane and beet juices is wholly dependent upon the technical control of manufacturing processes.

EXTRACTION

After passing the scales, the cars containing the cane are switched alongside the carrier which feeds the cane into the mills. Before the cane is unloaded, however, samples are taken from each car and sent to the laboratory, where they are carefully analyzed. The amount of sugar present is ascertained, as well as the quantity and quality of the juice in the cane. It is, however, impossible to get a fair average sample of the cane in this way, and therefore the efficiency of the mill work is determined on the basis of an analysis of the juice and the fiber after it has passed through the crushers.

[Illustration: TRAIN-LOAD OF CANE READY FOR THE MILL]

[Illustration: A MODERN MILL]

The carrier just referred to is a wide slat conveyor, running alongside the railroad tracks in the yards to a point directly over the first set of crushers. The cane is taken from the cars by a mechanical unloader, the arms of which reach out and with distended fingers pull the cane stalks off and land them on the slow-moving carrier, which takes them onward and upward to the crusher.

The crusher consists of two large rolls, with immense interlocking, corrugated teeth on the circumference of each. These rolls are set close together, and the cane passing through is broken into short pieces and matted to an even layer. The juice squeezed out by this preliminary crushing runs through a metal trough into a large receptacle known as the juice tank.

From the crusher the mat of cane passes to the mills proper. These mills consist of from nine to eighteen rolls, about thirty-four inches in diameter and seventy-eight inches long, arranged in groups of three, set in the form of an isosceles triangle, one above and two below, one set following the other in a direct line. The lower rolls are parted enough to allow the expressed juice to fall through them, while the half-crushed cane is carried over by means of an iron bar called the returner. The faces of the rolls are more or less roughened, or grooved, so as to draw the cane through and give a better crushing action. They are turned slowly by powerful engines, which transmit the power to each set of rolls through a system of gears. The rolls are forced together by hydraulic rams exerting a pressure of from four hundred to six hundred tons. It is this tremendous pressure that squeezes the sugar-bearing juice out of the cane.

From the crusher the matted cane passes through the first set of rolls, where a large percentage of the remaining juice is liberated. This is caught in a metal trough and, after passing over a fine screen to remove the small pieces of cane, runs to the juice tank. The cane passes through the second set of rolls, thence to the third set, and so on to the end of the mill. In front of the last set of rolls, hot water is sprayed on the cane to soften the fiber and dilute the remaining juice, thus aiding the final extraction. The adding of hot water is termed _maceration_. By the time the cane has passed through the last set of rolls, all the economically recoverable juice is out of it and delivered into the juice tank, with the exception of the juice and maceration water from the last set of rolls, which is always returned to the preceding set of rolls for maceration purposes. The juice or maceration water coming from the last set of rolls contains very little sugar, and the object is to secure greater concentration by using it for double maceration instead of adding that much additional water which would have to be evaporated later on in the process.

In well-designed, modern mills, with cane carrying not over twelve per cent of fiber, more than ninety-eight per cent of the sugar in the cane is extracted, the remainder being left in the fiber. This is almost perfection today. What it will be tomorrow no one can say.

The fibrous, woody part of the cane, or bagasse as it is called, is comparatively dry as it leaves the last rolls. It is conveyed from the mills to the boiler house on a wide slat conveyor, and fed directly into the furnaces under the boilers that generate the steam for power and boiling purposes. A modern raw-sugar mill requires practically no other fuel than that obtained as a by-product from the crushing of the cane.

The boiler plant is usually of large capacity, as a great deal of steam is required to drive the engines that run the crusher, the rolls, the electric lighting system, the pumps and other machinery. Besides, a large amount is needed to evaporate the water in the juice and to boil and dry the sugar. The ashes from the furnaces are returned to the fields as fertilizer, so that very little is lost.

[Illustration: CANE CARRIER AND MECHANICAL UNLOADER]

[Illustration: ANOTHER TYPE OF CANE UNLOADER]

PURIFICATION

The juice as it comes from the mills contains impurities such as dirt from the fields, small pieces of cane stalks and other foreign matter, besides salts, gum, wax and albumen. It is necessary to remove as many of these substances as possible, and this is where the chemist's work begins.

So long as the juice is confined in the living cells of the cane it does not quickly ferment, but when liberated it rapidly undergoes such change. Therefore no time is lost in arresting this action. The juice is pumped to the top floor of the mill and there a solution of milk of lime is added in sufficient proportions to neutralize the acidity. The mixture is then heated in closed tanks under pressure to 215 degrees Fahrenheit. The heat causes the lime to combine rapidly with the gums and salts in the juice, and the albumen to coagulate.

The hot juice is then run into large settling tanks, where the insoluble solids and the albumen sink to the bottom, carrying with them vegetable and other matter suspended in the juice. Certain foreign substances of light specific gravity float to the surface in the form of scum.

After settling for a time the clear juice is drawn off and the scum, mud and cloudy liquor left in the tank. As a vast amount of liquor must be handled every hour, it is not practicable to have tank capacity great enough to admit of the liquor standing a sufficient length of time for every particle of foreign matter to settle, so as an adjunct to the settling tank, filters are used. These are cylindrical iron tanks, packed tightly with ordinary wood fiber, known as excelsior. The juice is conducted to these filters, and as it percolates through the excelsior, practically all of the remaining foreign matter is caught and retained in the fiber. The clear juice is then run to the receiving tanks for the evaporators and the mud and scum that remain are drawn off into mud tanks, where more lime is added and the mass stirred up. Finally it is delivered to the filter presses, where the mud and other impurities are taken out and the clear liquor containing sugar is sent to the evaporators.

Another method for cleaning, called "precipitation in motion," is to carefully lime the juice and then heat it in closed vessels and under sufficient pressure to carry it through a pipe to large insulated settling tanks.

These settling tanks, usually of sheet steel, are made in the form of truncated cones with conical bottoms, the small diameter of the tank being at the top. Suspended in the center is a vertical cylinder somewhat less in diameter than the upper part of the tank. This cylinder extends downward about eight feet to a point opposite the largest diameter, which makes the area between the circumference of the suspended cylinder and the tank at that point very much greater than the area of the cylinder itself. This difference in area is necessary to retard the flow of the juice and allow the sediment, mud and insoluble solids to be deposited at the bottom of the tank.

The juice is delivered by a pipe into the top of the cylinder which projects a few inches above the edge of the surrounding settling tank. It passes slowly down the central passageway, turns at the bottom, where its speed is materially slackened, and goes out through a pipe line connected to the side of the tank just below the upper edge.

There are several other methods in general use, but in all of them the principle of settling, upon which the separation or cleaning depends, is the difference in specific gravity between the juice and the dirt. A high and even temperature should be maintained by

preventing radiation, as lowering the temperature would increase the specific gravity and viscosity of the juice without increasing that of the dirt in equal proportion.

[Illustration: TWELVE-ROLLER MILL]

[Illustration: MODERN CRUSHING PLANT—TWO FIFTEEN-ROLLER MILLS AND CRUSHERS. CAPACITY, ONE HUNDRED AND FIVE TONS PER HOUR]

There are many different types of filter presses, but those at present in general use are long, oblong machines, set horizontally on the floors, with layers of corrugated iron plates, covered with canvas sheets, between which are hollow frames so arranged that the juice will pass from the hollow frames through the canvas to the corrugations in the plates.

In passing through the presses under pressure the sediment, scum and other impurities are caught on the canvas sheets and the clear juice passes through the canvas, down the corrugations and out through small holes in the plates controlled by valves on the outside of the presses, from whence it runs to the evaporator tanks. The sugar in the mud caught in the hollow frames is washed out of the mud with water and is sent to the evaporator, while the mud itself is finally returned to the field, to be used as a fertilizer.

The clarified juice from the settling tanks, filters or presses, is light brown in color, but is thin and watery, and must now be reduced to syrup point. All the suspended impurities have been removed, but some impurities in solution and the original coloring matter still remain. Some of these foreign substances are subsequently eliminated during the process of crystallization in the vacuum pans described later on.

The object to be attained in a raw-sugar house is the production of a sugar containing ninety-six per cent of sucrose, and there is little or nothing to be gained by carrying the process of manufacture beyond the stage that insures such result.

The final extraction of all the impurities and the conversion of the impure raw into pure white granulated sugar is the work of the refiner, which is dealt with in a subsequent chapter.

From the time the juice leaves the cane until it is crystallized it is kept at a high temperature, as cold juices or syrups are viscous and run slowly. High temperatures kill germs, prevent fermentation and expedite manipulation.

EVAPORATION

Under ordinary atmospheric pressure at sea-level, water boils at a temperature of 212 degrees Fahrenheit and sugar juice at a few degrees higher, according to its density. This temperature if long applied to sugar juice would tend to burn and destroy the sugar, but the juice can be heated to 250 degrees for a short time without deterioration.

The clarified juice contains about eighty-five per cent of water and fifteen per cent of solid matter. A large proportion of the water must be removed by evaporation. To accomplish this under ordinary atmospheric conditions would require heat increasing from 212 degrees Fahrenheit, as the solution increased in specific gravity above the standard of pure water. This would require a large amount of fuel, and the juice would also be more or less adversely affected by long maintenance of comparatively high temperature.

To obviate these conditions the juice is boiled in a multiple evaporator, the invention of Norberto Rillieux, whose first construction in New Orleans in 1840 was a double effect horizontal submerged tube apparatus which has since undergone many changes and improvements. The theory of evaporation _in vacuo_ was extended to two or more cells or vacuum bodies, using the steam or vapor from the first to heat the juice or syrup in the second and so on. At the present time the quadruple effect, or four-cell evaporator, is most commonly in use, although sextuple effects are not rare. The ordinary practice is as follows:

The juice enters cell No. 1 and covers the heating tubes, to which is admitted sufficient steam—generally exhaust from the engines—to cause the liquid to boil. The steam or vapor liberated from this first boiling is conducted through the vapor pipe directly into the heating tubes of cell No. 2, while the juice from cell No. 1 is passed into the second, or cell No. 2, and surrounds the heating surfaces which contain the hot vapor given off from the same juice in cell No. 1.

[Illustration: DELIVERING BAGASSE TO FIRE-ROOM]

[Illustration: GENERAL INTERIOR VIEW OF MODERN RAW-SUGAR MILL]

As there is little or no pressure above the liquid in the first cell, the juice boils at from 215 degrees to 220 degrees Fahrenheit. By maintaining a vacuum of five inches in the second cell, the temperature at which the liquid will boil is reduced to 203 degrees, and the vapor from cell No. 1 is hot enough to boil the juice in cell No. 2 without any addition of heat. The vapor from cell No. 2 in the same way enters the heating tubes of cell No. 3, while the juice entering this cell is exposed to a vacuum of fifteen inches, which reduces the boiling temperature to 180 degrees, so that the difference of 23 degrees between the conditions of cell No. 2 and cell No. 3 causes a third boiling and evaporation without any additional steam being added.

A vacuum of twenty-six inches in the last cell, No. 4, brings the final boiling temperature down to about 150 degrees. The vapor from this last cell enters a condenser, where it is exposed to a spray of cold water, is condensed and passes down a pipe not less than thirty-four feet long, terminating in a water seal, and called the Torricellian tube, after Torricelli, who discovered that mercury would rise thirty inches in a tube while water would rise thirty-four feet with a perfect vacuum.

The juice in passing through these evaporating cells is boiled to a syrup containing about thirty-five per cent of water and sixty-five per cent of solid matter. It is pumped out of the fourth cell into the receiving tank for the vacuum pan.

This quadruple system of boiling only requires about one-fourth the amount of heat that would be necessary to do the same work in a single vessel. As the evaporators operate continuously, a constant level of the boiling liquid is maintained in each cell, the juice being drawn from one to the other by increasing vacuum and controlled or regulated by means of valves.

A powerful vacuum pump draws the air and other incondensable gases from the condenser and maintains the vacuum, which is applied to the necessary extent in each cell. The heating tubes are connected to drain pipes, which remove the condensed vapors.

Vacuum, simply and concisely stated, is the absence of air or gas. It is usually obtained by pumps which suck the air or gas out of closed containers or pipes. No doubt many of the readers in their younger days have sucked on the end of a bottle and were amused to find the bottle hanging on the end of the tongue. It was the vacuum, or lack of air in the bottle, which caused it to hang thus. The outside atmospheric pressure (which at sea-level is fifteen pounds per square inch) was doing its best to gain an entrance through the tongue into the bottle from which the air had been extracted.

The pumps simply suck the air out of the containers or pipes and discharge it through valves, in much the same way that the air was sucked out of the bottle. It must be remembered, however, that in boiling water or juice, the vacuum is being continually broken or reduced by the liberation of air and gases from the juice, steam and condensing water. This action must be overcome by the constant work of the vacuum pump.

To determine the amount of vacuum carried in any container, a small mechanical contrivance, known as a vacuum gauge, is used. This, in its simplest form, is a bowl of mercury with a long glass tube leading from it. If the upper end of the glass tube is attached to the container from which the air is to be drawn, the mercury in the tube will rise in proportion to the amount of air extracted. When an absolute vacuum has been formed, the mercury in the glass will stand at a height of thirty inches.

[Illustration: FILTER PRESSES]

[Illustration: SET OF QUADRUPLE EVAPORATORS]

In commercial operations a vacuum greater than twenty-eight inches is seldom required, as this is sufficient for all practical purposes. The degree of vacuum for any container can be varied easily by mechanical manipulation, so that a vacuum anywhere from one to twenty-eight inches may be maintained.

CONCENTRATION AND CRYSTALLIZATION

From the receiving tanks the syrup is drawn into the pans by a vacuum ranging between twenty-five and twenty-seven inches. The pans are large cast-iron or copper cylinders, standing in a vertical position, with dome-like tops and conical bottoms, almost spherical in shape. Leading from the top is a large pipe through which the vapors from the boiling are drawn off and condensed. On the conical bottom is a large valve, which may be opened when the boiling is finished to allow the _massecuite_ (a French term meaning cooked mass) to drop out.

At regular intervals in the height of the pan there is a series of copper coils, connected with a steam line at one end and a drain line at the other.

The general principle involved in boiling sugar is the separation of the sucrose contained in a solution from the impurities present in that solution, and this is accomplished by evaporation and concentration through the agency of heat. After the sugar is once formed in definite crystals these crystals attract and appropriate the sucrose in solution in the process of building up the crystal structure, while repelling or excluding the impurities, so that, as a consequence, the latter remain in solution. The crystals thus formed are subsequently removed from the solution by means of centrifugal machines. Crystallization, whether in a pure or impure solution, will proceed to only a certain extent, and will only partially remove the sucrose from the solution in one boiling, the limit of crystallization being governed by the amount and nature of impurities present.

The process of boiling is begun by drawing some of the concentrated juice into the pan and turning steam into the coils, which starts the boiling. This is continued until the supersaturation is such that minute crystals of sugar form or “grain out.” By properly timed admissions of fresh concentrated juice, drawn into the pan by vacuum as before, the crystals grow in size and at last the pan becomes filled with a mass of sugar crystals of regular shape and size, immersed in a thick “mother liquor” containing sugar and the impurities that were not removed by the filters or settling tanks.

The size of the grain may be varied at will by the operator in charge, who is known as the sugar boiler. After the grains are once formed, their number (if the sugar boiler is an expert) does not increase, but the size does, as the original grain continually builds up on itself from the outside.

The question may be asked, why is all the moisture not boiled out in the pan and the sugar dropped in a dry, crystallized state? There are several reasons why such a course is impracticable; first, because the impurities, which must be eliminated by crystallization and which are carried off in the mother-liquor, would be boiled into the sugar and make it unsalable; second, because to aid crystallization and prevent scorching or burning on the hot steam coils the mass must be kept in active circulation during the boiling process, or, long before all the moisture could be driven off, a large part of the contents of the pan would be burned on the coils; and third, even if it were practicable to boil the contents down to a solid state, the grains would stick to each other and become one solid mass, which would have to be removed from the pan with bars, picks or chisels. Enough moisture, or rather liquor, is left in the mass to enable it to flow from the pan by gravity. This liquor, with the impurities it carries, is subsequently removed from the sugar by a drying or separating process which will be explained later on.

Massecuite is a viscous, sticky, semi-fluid mass of the consistency of half-formed ice.

[Illustration: VACUUM PANS]

[Illustration: CENTRIFUGAL MACHINES]

The reason sugar “grains” is because the water in the juice has the power to hold in solution only so much sugar. As it goes into the pan, the juice is almost a saturated solution, and as the water is driven off by evaporation, the solids that up to this point have been in solution must of necessity crystallize.

When the sugar boiler decides that the “strike,” that is, the massecuite contained in the pan at one boiling, is satisfactorily grained, he breaks the vacuum by opening a valve on the top of the pan, thus allowing the air to enter. He then opens the valve at the bottom of the pan and the mass drops into a long tank with a rounded bottom, called the mixer, in which a shaft, equipped with paddles, is revolving. The paddles are for the purpose of keeping the mass agitated and in an even condition. The agitation prevents the grains from dropping to the bottom of the tank and forming a solid block, called concrete.

PREPARATION OF CRYSTALS FOR THE MARKET

From the mixer the massecuite runs through spouts into the centrifugal machines. Centrifugal machines are cylindrical-shaped, perforated brass baskets, usually forty inches in diameter and twenty-four inches deep, hung on a central shaft suspended from beams overhead, and surrounded by a solid outside curb or casing.

On the shaft is a pulley, which is driven by a belt connected with an engine or an electric motor. The inside of the basket is lined with a fine-meshed brass screen, which retains the grains of sugar, but allows the liquor to escape freely into the outer casing.

As soon as the centrifugal machine is filled with massecuite from the mixer above, the power is turned on and the machine begins to spin around at an increasing speed until a velocity of one thousand revolutions per minute is reached. The centrifugal action forces practically all the liquor out through the screen and leaves in the machine all the grains of sugar that were formed in the pan. A little dry steam is sometimes turned in to assist in reducing the moisture in the sugar.

The centrifugal is then stopped, a valve in the bottom is opened, and the nearly dry crystallized raw sugar is dropped into bins. From the bins it is drawn off through spouts and packed in sacks containing about one hundred and twenty-five pounds each.

It has been demonstrated that raw sugar containing a large amount of moisture inverts or deteriorates more rapidly than that with a low-moisture content. It is apparent that as moisture adds to the weight, the transportation charges, which are based on tonnage, are greater in the case of wet sugar than in the case of dry. In many of the modern mills, therefore, a further treatment is given the sugar to reduce loss by inversion and lessen freight charges.

From the bins last mentioned the sugar is dropped into revolving drums six feet in diameter and twenty-six feet long, set at an incline so that as the drum revolves the sugar is carried round to the highest point on the circumference of the drum and dropped to the lower side, at the same time traveling from the receiving to the discharging end. The shape, motion and inclined position of the drum cause a perfect shower of sugar in the drum for its entire length and breadth. While it is revolving a current of hot, dry air is drawn through the drum by means of suction fans, and as a result the moisture in the sugar is absorbed by the air and carried out of the building. At this stage the product has a good hard grain of a yellowish-brown color; contains from ninety-six to ninety-seven per cent of pure sugar and about one-half of one per cent of moisture.

[Illustration: FILLING, WEIGHING AND SEWING SACKS]

[Illustration: TRAIN-LOAD OF RAW SUGAR LEAVING MILL]

From the end of the revolving drum the sugar is drawn off into sacks holding about one hundred and twenty-five pounds each. These sacks are sewed by machinery and put into railroad cars to be hauled to the docks at the shipping port, where the cars are switched under huge hoisting cranes or alongside speedy conveyors which carry the sugar into large seagoing steamers especially built for the trade. Some of these ships have a cargo capacity of two hundred and twenty thousand sacks, and they transport the sugar to the buyers on the mainland in San Francisco, New York or Philadelphia, as the planter directs.

The liquor thrown off by the centrifugals is not lost; it is taken back to the pans and reboiled. After this has been done several times and most of the sugar extracted, the purity is so low and the sugar content so small that it does not pay commercially to reboil further, and the residue is sold as molasses. It contains about thirty-five per cent of sugar and from twelve to fourteen per cent of invert sugar, or glucose, as it is generally called.

Some of the waste molasses is mixed with fodder and tender cane tops and fed to cattle and plantation stock, the sugar content proving of great value as a fattening agent and energy builder. Part of the molasses is sprayed on the bagasse as it leaves the crushers and serves, first, as a fuel under the boilers, and, second, as a fertilizing agent in the form of ashes after it has been burned. During the past few years much of it has been shipped in tank steamers to the mainland, where it is used for the manufacture of spirits and vinegar, and also as the principal ingredient in prepared stock foods which are much in demand today.

Every bag of sugar shipped from the plantation is marked to indicate the plantation from which it came. The net weight of the sugar in each bag is recorded, a sample of the sugar taken and its sucrose content ascertained, for it is on the basis of weight and sucrose content that raw sugar is bought and sold.

From the beginning to the end of the process of manufacture, chemists are vigilantly alert sampling, testing, analyzing and supervising the operations. Records are made of all analyses, temperatures, purities, densities, extractions, etc., and the results tabulated for future reference.

The average cost in Hawaii of preparing the fields, planting, irrigating, fertilizing, cultivating and cutting the cane, manufacturing the sugar and delivering it in the New York market, is about $56.00 per ton of two thousand pounds.

TRANSPORTATION AND DELIVERY OF RAW SUGAR

It has been explained that in Hawaii sugar is packed in one-hundred-and-twenty-five-pound sacks. Methods and customs vary in different countries. For instance, in Cuba it is put up in large gunny bags, each holding an average of three hundred and twenty-five pounds. The same custom prevails in Porto Rico. In Peru, and to a limited extent in Java, sacks containing two hundred and twenty-four pounds are used. A large part of the sugar in Java, however, is put up in bamboo baskets of native make, containing from five hundred to eight hundred pounds. They are about thirty inches in diameter, from thirty-six to forty-eight inches high, and are lined with coarse leaves to prevent the sugar from sifting out between the weavings of the bamboo. Philippine sugar is packed

in leaf-lined mats of tough vegetable fiber, each holding about seventy pounds.

These various styles of containers necessitate different methods of handling to and from the ships and by the buyers, but Hawaii will again serve as an example of efficient, modern practice. Outside of what is consumed locally, all Hawaiian sugars are shipped to the mainland of the United States by steamers or sailing vessels to San Francisco, or by steamers to New York or Philadelphia, via the Panama canal.

As sailing vessels are rapidly disappearing from the seas so far as the sugar trade is concerned, reference will be made to steamer traffic only. The steamers are specially built for carrying sugar, having a cargo capacity of from five thousand to thirteen thousand tons, and the best loading and discharging facilities.

When loading in Honolulu, the steamers usually lie alongside wharves covered with immense warehouses, where rapid-speed conveyors carry the sacks of sugar to a point above the ship's hatches and drop them into chutes which guide them down into the hold of the ship, where they are compactly stowed. On the off-shore side of the vessel small steamers from other island ports lie alongside and hoist the sacks by means of steam winches to a point over the hatch and deposit them in similar chutes. When steamers are loaded from both sides in this manner, as much as three thousand tons, or forty-eight thousand sacks, can be loaded in nine hours.

After a vessel is completely loaded and gets her clearance from the custom house, she departs for San Francisco, twenty-one hundred miles away, or for the Atlantic seaboard, via Panama, as the planter may direct.

The voyage ended, and the quarantine and health regulations complied with, she proceeds to the dock of the buyer, usually a sugar refiner. The Hawaiian planter invariably sells his sugar under contract prior to arrival of the vessel at destination.

Planters in other countries operate differently. Occasionally sugar is sold on the plantation at an agreed price, and the buyer arranges his own transportation. The planter sometimes ships his sugar unsold and negotiates its sale while it is en route. If so sold, it is delivered directly to the buyer on arrival; if not, it must be stored in a warehouse at the planter's expense pending sale.

The practice of the Hawaiian planter is to sell his sugar to refineries in San Francisco, New York or Philadelphia, under contracts extending over a term of years. It is agreed that the sugar shall be shipped as soon as made and that the refiner will receive it immediately on arrival, the price for each cargo being that quoted in the open New York market for ninety-six-degree centrifugal sugar on the day preceding its arrival.

[Illustration: STEAMER LOADING SUGAR ALONGSIDE DOCK]

[Illustration: LOADING SUGAR AT AN OUTPORT IN HAWAII]

The value of raw sugar, like that of other staples, is based on supply and demand, and the price fluctuates from day to day according to the requirements of the refiners or the necessities of the sellers.

There are certain rules or trade conditions governing all sales, so that when one man buys and another sells at an agreed price, each knows what he is bargaining for. For instance, raw sugar is bought on the ninety-six-degree centrifugal basis, that is, the price agreed to be paid is for centrifugal sugar containing ninety-six per cent of sucrose. If it contains more sucrose, a higher price is paid; if it contains less, a lower price is paid; all according to an established scale of additions and deductions. Then again, the time of payment for the sugar is well understood. It is usually ten days after the sugar has been finally discharged from the ship, as this allows a sufficient period in which to determine the exact weight of the sugar and the percentage of sucrose it contains. An instrument called a polariscope is invariably employed to determine the amount of sucrose present and the results obtained from its use are absolutely accurate. A description of the operation will undoubtedly prove interesting.

POLARIZATION

The practical working of the polariscope is based upon the property of sucrose to rotate a ray of polarized light to the right.

Ordinary light is the effect on the eye of vibrations of the ether. These vibrations occur in all directions, but by certain optical devices they may be confined to a single plane, and light thus confined is called polarized. If rays of polarized light pass through a layer of certain bodies, _e. g._, quartz, sugar and many others, the plane in which the vibrations occur is rotated, and the polariscope has been devised for the purpose of measuring the rotation of the plane of polarization.

Polarized light, as used in the polariscope, is obtained from the Nicol prism or some development of it. Ordinary light passing through crystals of certain bodies, of which Iceland spar is an example, is split into two rays, one of which is known as the ordinary and the other as the extraordinary ray. A Nicol prism is made of two wedge-shaped pieces of Iceland spar, cemented together with a film of Canada balsam.

The accompanying sketch gives a good idea of the arrangement of an ordinary polariscope.

[Illustration: POLARISCOPE]

A strong white light, _e_, enters the instrument through a lens at _f_, to the Nicol prism _b_, by which it is polarized. The ordinary ray is dispersed, while the extraordinary or polarized ray passes straight through and enters the sugar solution contained in the tube _c_, which has glass ends. In passing through this solution it is given a rotary motion to the right or to the left, according as the sugar in the solution is sucrose or levulose. When it emerges from the tube containing the sugar solution, the now rotated polarized ray encounters a second Nicol prism, of which one of the wedges is fixed and the other movable. This prism is called the analyzer. A pointer, controlled by a thumb screw, is attached to it, and when the correction of the polarized ray's rotation has been made with precision by adjustment of the wedges, the pointer will indicate directly and accurately on a scale the amount of sucrose in the solution under test, because the polarized ray was rotated in exact proportion to the amount of sucrose contained in the solution through which it passed.

The polariscope is made and set so that a standard weight of pure sugar (C■■H■■O■■), dissolved in a standard quantity of pure water, and placed in a tube of given length, will rotate the ray of polarized light in passing through, to a point on the scale marked one hundred degrees, the equivalent of per cent. Also, that by using the same quantity of water, but twenty-five per cent, fifty per cent, or seventy-five per cent less weight of sugar, the rotation will show seventy-five degrees, fifty degrees or twenty-five degrees of pure sugar, as the case may be.

A sample is drawn from each bag of sugar and all of these go to make up a general average sample. The standard quantity is carefully weighed, dissolved with the standard amount of water, clarified, filtered and poured into a tube with glass ends, which is then inserted in the polariscope between the eye of the operator and a strong artificial light. When the operator making the test applies his eye to the instrument, he sees a distinct shadow on a lens in the line of vision, one side being light and the other dark. He then turns the thumb screw which adjusts the analyzer until the whole field of vision is neutral, which indicates that the rotation of the polarized ray has been corrected. The pointer on the scale now shows the exact percentage of sucrose present in the raw sugar, ninety-four, ninety-five, ninety-six degrees, or whatever it may be. This test determines the real value of the sugar, based on the market quotation for ninety-six-degree sugar. If the polarization should show exactly ninety-six degrees, the price to be paid for the sugar and the market quotation will be identical.

In most sugar-producing countries the government imposes an import tax on all foreign sugars, in order to obtain revenue to defray governmental expenses and to protect the domestic industry, if any, against competition with other countries in which cost of materials and labor may be lower. Commodities produced in a country naturally add to its development and wealth, and this explains the fostering of the sugar industry by various governments.

The United States duty on foreign sugar is at present $1.256 per one hundred pounds of ninety-six-degree raw sugar. On account of our treaties with Cuba, the Cuban planter is allowed a deduction of twenty per cent, and, therefore, pays a duty of $1.0048 per hundred pounds, which, owing to trade conditions, is the duty effective today in the United States.

Sugars produced in the insular possessions, Porto Rico and the Philippine islands, are admitted free of duty.

In 1898, the Hawaiian islands, through annexation, became a part of the United States, consequently no duty is assessed on sugar or any other Hawaiian product.

Every vessel coming into a port of the United States must be entered at the custom house, where a record is kept of the port whence she came and of what her cargo consists. If from a domestic port, she is permitted to discharge her cargo without delay; if from a foreign one, customs officials are immediately sent on board to watch the cargo as it is discharged and supervise the tallying, checking or weighing, according to the class of merchandise. Besides being weighed, sugar is carefully sampled and the percentage of sucrose ascertained by the polariscope, for the customs duty is based upon the purity of the sugar, all raws testing not above seventy-five degrees polarization paying .71 cent per pound and .026 cent per pound for each additional degree. This is equivalent to 1.256 cents per pound for ninety-six-degree sugar.

The people of the United States used 4,257,714 short tons of sugar in the year 1915. It was nearly all produced within the United States or in countries enjoying tariff concessions, as follows:

SHORT TONS Hawaiian islands (Cane) 570,375, U. S. territory. Louisiana (Cane) 251,740, U. S. territory. Domestic production (Beet) 861,568, U. S. territory. ” ” (Maple) 17,248, U. S. territory. Porto Rico (Cane) 336,347, insular possession. Philippine islands (Cane) 134,626, insular possession. Cuba (Cane) 2,062,594, reciprocity treaty. Foreign sugar (Cane) 23,216, full duty-paying. ---------- 4,257,714

Aside from the small amount of full-duty-paying foreign sugar imported, the only sugar in the above list that paid duty came from Cuba. It is evident, therefore, that under ordinary conditions an increase in the crops of any of the places mentioned would result in a surplus of sugar in the American market. In 1916, with the beet production of Continental Europe locked up by the war, Cuba’s increased output has been absorbed by Great Britain, France, Italy and Greece.

Steamers from Hawaiian ports, after arriving and entering at the custom house and passing quarantine and health officers, proceed immediately to refinery docks to discharge cargo.

REFINING OF RAW SUGAR

Cane-sugar refineries are always located in great seaport towns for the reason that, as practically all cane sugar is grown in the tropics, it must be transported by water to the world’s markets.

The refining operation is by no means as simple as may at first appear. It is essential that the finished product be almost chemically pure (99.8 per cent), and the greatest care must be exercised to obtain a perfectly white color, as well as a hard, lustrous grain.

The question naturally arises, why do not the planters of Hawaii, Cuba, Java and other raw-sugar-producing countries carry their process a few steps further and make a pure white sugar as the refiners do? This has been attempted many times, but has almost always been found impracticable, notwithstanding the fact that there is no mechanical or chemical reason why.

Among the arguments in favor of a mainland seaport site, the following may be mentioned:

1. The producing centers are generally far distant from consuming markets. Refineries located in the tropics would be under unusual expense for transporting and selling the refined article.

2. A refinery in the tropics would be out of direct and prompt touch with the individual requirements of the buyers.

3. Refined sugar should be moved and sold as soon as possible after its manufacture, so there follows the necessity for adequate dock and rail facilities as means of quick communication with the market.

4. An abundant supply of pure, soft water for refining purposes, and salt or fresh water for condensing, as well as fuel for the generating of steam, must be readily available. Another most important requisite is skilled labor, which is more easily obtained in populous seaport cities than in the small, isolated towns of the tropics.

5. There are many commodities used in the refining of sugar and in packing it for shipment that can be purchased more advantageously, both as regards price and promptness of delivery, in the great commercial ports than in the sugar-growing districts. Among these are bone-char, lime, acids, cotton filter-bags, burlap, cotton cloth, boxes, barrels, cartons, iron, steel and machinery of all kinds.

6. A sugar refinery is operated the entire twelve months of the year, while a raw-sugar mill must of necessity take care of the crop of cane in about eight months. To refine sugar where it is grown would require refining machinery capable of handling the entire output in the eight-month period, and during the remaining four months the plant would remain idle. This would mean a larger investment proportionately than that made in a refinery in a consuming center, running steadily the year round.

7. Refined sugar very rapidly absorbs moisture, and while in transit from the tropic to the temperate zone it is very apt to become lumpy or caked, which would involve reprocessing at great expense at the point of consumption. The unavoidable damage to the packages in loading and discharging results in heavy expense, as all packages must be delivered to the buyer in first-class condition. To avoid hardening, refined sugar should never be piled very high, and it is an unsolved problem whether refined sugar will stand long ocean transportation in cargo lots without caking and damage by breaking of the inside cotton sacks. If shipped in

barrels, the freight rate is proportionately higher.

8. Larger capital would also be required, as refined sugar must be carried on hand and must await the consumer's demand, while raw sugar generally has a prompt and ready market and can be quickly converted into cash.

With these difficulties presenting themselves to a prospective sugar refiner in a raw-sugar-producing country, the shipping of raw sugar to refineries at great distances does not seem at all unreasonable.

Raw sugars show considerable variance in their component parts, and so it follows that some are less easily refined than others. Such differences are generally due to diverse methods of culture, amount of fertilizer used, the processes of manufacture and the efficiency of extraction. If the extraction be high, a large percentage of the salts in the cane is taken up, and these salts prevent or retard the complete crystallization of the pure sugar in refining. One part of ash prevents several times its own weight of sugar from crystallizing, hence it is readily seen that raw sugars with a low ash content are preferred by refiners.

[Illustration: A MODERN REFINERY—SHOWING WATER AND RAIL TRANSPORTATION FACILITIES]

[Illustration: PLAN ELEVATION OF A MODERN REFINERY]

Sugar refining is the production of pure white sugar in granular form, after the removal of the impurities from the raw product. Nine operations are necessary to bring about this result:

1. _Washing_:

Removal of superfluous impurities.

2. _Melting_:

Changing the solid raw sugar into liquid form by melting with water.

3. _Defecation_:

Precipitation of suspended and insoluble impurities.

4. _Bag and Bone-char Filtration_:

Removal of suspended impurities, color and soluble impurities.

5. _Crystallization_:

Production of crystals by concentration.

6. _Partial Drying_:

Purging crystals from syrup in centrifugals.

7. _Final Drying_:

The driving off of all remaining moisture.

8. _Sorting of Crystals_:

Sorting of grains according to size to meet market demands.

9. _Packing_:

Putting in various forms of containers.

A refinery consists of a group of buildings, each of which has been constructed for a special purpose and for convenience and economy in operation. They are as follows:

1. The melt or wash house. 2. The char house. 3. The pan house. 4. The packing house. 5. The boiler house. 6. The pump and power house.

In addition there are offices, shops, laboratories, and last, but by no means least, very extensive warehouses.

To begin at the beginning it will be necessary to start with the steamer laden with raw sugar and made fast to the wharf in front of the warehouse that forms part of the refining plant.

The sugar is hoisted out of the ships in sling-loads by powerful winches, and landed on a platform on the dock alongside the ship. Each sling-load consists of from twelve to twenty sacks, or the equivalent weight in baskets or mats, as the case may be. As soon as the sacks are landed, they are sorted according to mark, put on trucks to be run over a scale set in the floor, and their gross weight recorded.

As the truck leaves the scale, the samplers take a sample from each sack. This is done with a tryer, a long, hollow steel tube, open on one side and sharp at one end, with a handle on the other for the sampler to grasp when forcing the tryer into the sack. The individual sample from each sack of each different mark is deposited in large closed cans until the cargo is completely discharged, when an average sample of all the individual samples of each mark is made up and used in the laboratory to determine the polarization or sucrose content of the various lots comprising the entire cargo. The value of the sugar is fixed by this polarization.

The weights of the various truck-loads of sugar passing over the scales are totaled and the weight of the sacks, baskets or mats deducted, giving the net weight of the sugar.

Hawaiian sacks weigh exactly one pound; Cuban, Javan and Peruvian sacks about three and one-half pounds. Javan baskets weigh from twelve to fifteen pounds, and Philippine mats about four pounds.

In order to facilitate the weighing and simplify the calculations, in cases where the exact weight of the sacks is known, every truck is made to weigh the same by ascertaining the weight of the heaviest and then putting small iron nuts or washers on the rods of the other trucks until each of them exactly counterbalances the heaviest. One truck is then placed on the scale and the scale is brought to a perfect balance, just as though there were no truck on it. In this way the weight of the truck is never recorded, which greatly simplifies the entire weighing operation.

One crew of men will discharge from 1300 to 1500 sacks of sugar per hour from each hatch of a steamer, or a minimum of 731 tons per day of nine hours. As three hatches are usually worked at the same time, it will be seen that from 2200 to 2500 short tons are taken out every day.

[Illustration: STEAMER DISCHARGING RAW SUGAR AT REFINERY DOCK]

[Illustration: SUGAR STORED IN WAREHOUSE—TWENTY-FIVE THOUSAND TONS SHOWN IN THIS PICTURE]

From the scales the sugar is deposited on a depressed conveyor in the floor and carried directly into the melt house of the refinery, except the sugar that must of necessity be stored in the warehouse for future use, in which case it is dumped from the trucks on piling machines that elevate it to any height desired, and it is arranged neatly and compactly by the piling crew.

The wharves and docks of a sugar refinery are, as a rule, scenes of unusual activity and interest. Besides the large number of men engaged in hoisting, trucking, weighing, sampling and piling the sugar, there are the sailors, whose calling always possesses a certain fascination for the landsman. A motley crew they are, bronzed by wind and sun, gathered from all countries and climes. There is the simple, kindly native of Hawaii, gentle-eyed, soft of speech and born with a love for the sea; he prides himself upon his skill in swimming and diving, and when the day’s work is done, entertains his shipmates by singing the plaintive melodies of his native land, accompanying himself on the ukulele, the stringed instrument of the South Seas. Should there be a number of his fellow islanders among the crew, the evening’s program is almost certain to be varied by the native hula hula dance, which generally brings marked applause from the onlookers. Presiding over the galley, or ship’s kitchen, is the almond-eyed Chinaman, now shorn of his queue; an excellent cook who loves to gamble after his pots and pans are washed and put away in place; a shrewd gamester, but scrupulously honest. Beside him stands a fierce-looking Malay, sullen, morose and taciturn, whose sharp, white teeth carry a sinister suggestion of the good old days of cannibalism. His neighbor is a Filipino, short in stature, keen-eyed and alert, while in the background are one or two individuals who from their appearance might be direct descendants of the buccaneers who ravaged the Spanish Main in Sir Henry Morgan’s time.

The average sailor is fond of pets, and here there is no lack of them, parrots and monkeys for the most part, and the sayings of the former clearly indicate a total absence of Sunday-school training.

Sugar ships bring rare fruits and vegetables from the tropics, and the employés of the refinery have plenty of opportunities to enjoy such luxuries as fresh pineapples, bananas, guavas, papaias, alligator pears, breadfruit and mangoes.

A visit to the docks of a sugar refinery during the time vessels from foreign ports are lying there is well worth while, although in these days of steam, the picturesque features are not so pronounced as they were before the passing of the sailing vessel.

WASHING

REMOVAL OF SUPERFICIAL IMPURITIES

As a starting point in the refining process the melt house will be first considered. It is so called because it is there that the raw sugar enters the refining process by being melted or dissolved in water.

The conveyor, upon which the bags were deposited in the warehouse, delivers them on a platform on the top floor of the building. As they come to this platform from the conveyor, workmen with keen-edged knives seize them and, with a deft, swift slash, cut the twine sewing at the top of the bag without injuring the burlap fabric. The bag is then pulled off the platform, mouth downward, so that the sugar falls out and passes through an iron grating into a large bin beneath. If the sugar should happen to be caked or lumpy, it is sent through crushers and broken up.

[Illustration: CUT-IN STATION—SHOWING SUGAR FIRST ENTERING THE REFINING PROCESS]

[Illustration: CENTRIFUGAL MACHINE—MOTOR DRIVEN]

As a certain amount of sugar adheres to the inside of the bags, they are washed in large revolving machines and in this operation the sugar dissolves in the water (called sweet water), from which it is extracted later. They are then partially dried in centrifugal machines and hung on hooks on a traveling chain conveyor that passes through the upper part of the boiler house, where the waste heat thoroughly dries them. In returning, the conveyor passes through the bag room and, by means of an automatic device, the bags are dropped alongside the printing presses. Here the name of the refinery, the kind of sugar and the net weight they are to contain are printed upon them. These burlap bags are then lined with a white cotton bag, after which they are made into bundles and sent to the packing room to be filled with sugar. It will be seen, therefore, that the bags from Hawaii in which the raw sugar is received are put to good use. This, however, does not apply to those that come from Cuba or Java; they are too large to serve as containers for the refined product, and after being washed and dried are sold for what they will bring.

The white cotton bags are made at the refinery, and a plant turning out one thousand tons of sugar each twenty-four hours will use twenty-five thousand yards of cotton sheeting per day if all the output is packed in one-hundred-pound bags.

The bin into which the raw sugar is dumped holds enough sugar to keep the refinery supplied during the twenty-four hours run, but the entire quantity is “cut in” during the day. The advantages of this arrangement are that it avoids any delay in operation due to mechanical troubles with conveyors and because more efficient work is accomplished during the daylight hours. The employés prefer to work on the day shift and, wherever possible, night work is avoided.

From the bottom of the bin the sugar falls into a mixing machine, called the mingler. This is an oblong tank with a semi-cylindrical bottom, near which is a revolving horizontal shaft, with arms or paddles attached which thoroughly stir and mix the sugar with syrup that is added at this point. The reason for using syrup instead of water is that the former, being a saturated sugar solution, does not melt the sugar as water would.

The resultant mixture, called magma, looks a good deal like a soft, brown mortar. It is, in fact, raw-sugar crystals swimming in syrup. This consistency is needed to allow the magma to work freely in the centrifugals, the next operation. Most of the impurities contained in raw sugar are superficial, that is, adhering to the outside of the grain. They may be more or less readily removed by washing the surfaces of the crystals with water.

From the mingler the magma drops to the floor below into centrifugal machines running at the rate of 1100 revolutions per minute. A “charge” consists of about nine hundred pounds of magma. As the machine fills, the centrifugal force causes the magma to rise in a vertical wall around the inside circumference of the basket, at the same time throwing off the syrup that was added on the floor above, and leaving in the machine about five hundred pounds of the raw sugar as it came from the plantation. Water is then sprayed into the machine under high pressure, through a nozzle which divides it into very fine particles and throws it against the wall of sugar in the machine. The water, passing through the sugar by the centrifugal force, washes each face of each crystal and carries off the impurities, together with a certain amount of sugar. The quantity of water used per machine in each filling is from one to two and a half gallons, depending upon the quality of the sugar.

This water, now a syrup, with the impurities and sugar it contains, is drawn from the machine, part of it being pumped to the floor above to mix with new raw sugar coming in. The remainder is treated, filtered, boiled and made into raw sugar, which, in turn, goes direct to the melt or through the washing process again. The result of this washing is that the purity of Hawaiian raw sugar is raised from about 97.2 to 99.2 per cent, and there now remains but 0.8 per cent of impurities to be removed.

The washed sugar is dropped from the centrifugal basket through a large opening in the bottom of the machine with the aid of a mechanical device called a discharger, which greatly reduces the manual labor.

Until very recently the sugar was discharged from the centrifugals by hand, the men digging it out with wooden paddles in a difficult, laborious way. One day, a few years ago, a clear-brained, observant American lad working in a beet-sugar factory, conceived the idea that a centrifugal could be emptied by mechanical means. He worked long and assiduously upon the problem, and after much experimenting and many trials and disappointments was granted a patent by the United States government. Full of hope and confidence, he had several machines constructed and took them to a sugar refiner, sure of being favorably received. He met with rebuff and ridicule. The refinery engineer was too busy with other matters to examine or give any attention to the appliance. The next man to whom he presented it was even more indifferent than the first; he coldly informed the patentee that he had been in the sugar business for thirty years, that no such machine would work, and that the only way to take sugar out of a centrifugal was by hand.

After months of effort and repeated failures, he induced the superintendent of a beet-sugar factory to allow him to install and test the device at his own expense. It was thrown out after a few days' trial, and the inventor became well-nigh desperate, although still positive as to the merits of his discharger.

Finally he succeeded in gaining the ear of the manager of a large refinery, who, after listening attentively to his earnest argument, at length became convinced by it. As a result of the interview, it was arranged between them that the machines rejected by the beet-sugar factory should be installed in the refinery and operated for a period of thirty days, under the direct supervision of the inventor. The test was successful in every particular and conclusively proved the efficiency of the discharger.

The refiner was gratified because on account of the saving in time the capacity of the centrifugals was materially increased; the men operating the centrifugals were hugely pleased, as the arduous work of emptying by hand was entirely eliminated, and the inventor was happy, for he had vindicated himself.

An order for a large number of the machines was placed at once and every centrifugal in the refinery was equipped with one. Today they are installed in nearly every refinery and factory in the United States, and in many raw-sugar plantation mills as well.

MELTING

CHANGING THE SOLID RAW SUGAR INTO LIQUID FORM

From the centrifugals the washed sugar drops to the melter pan on the floor below. This is a cylindrical tank in the center of which is a revolving vertical shaft, to which are attached horizontal paddles that serve to facilitate the dissolving of the sugar with the hot water that is now added. Only enough water is added to bring the resultant liquor to a density of 58.6 per cent of solid matter.

The raw sugar having been washed and, to use a technical term, _melted_, leaves the melt house at this point.

DEFECATION

PRECIPITATION OF SUSPENDED AND INSOLUBLE IMPURITIES

From the "melt" the liquor is pumped to the top floor of the char house, which is usually a structure of from twelve to fourteen stories high. The reason for building to such a height is the advantage gained by utilizing the force of gravity and by this means handling the liquors and bone-char from floor to floor without mechanical aid.

The liquor is delivered into a number of cylindrical tanks equipped with a coil of pipe through which steam is passed for heating the liquor, each tank being capable of holding 25,000 pounds of liquor. Around the bottoms of the tanks are perforated pipes through which compressed air is forced to agitate and thoroughly mix the solution. On account of this air being blown in, these tanks are called blow-ups. By means of the steam coil the temperature of the liquor is kept at 190 degrees, which makes it less viscous than cold liquor, thus facilitating subsequent filtration and hastening the reaction of the lime and acid added at this point.

As the liquor comes into the blow-ups it varies in color from a straw yellow to a dark brown, and contains a considerable amount of suspended and insoluble impurities which must be removed. Some of these impurities are present in the raw sugar, and others, such as pieces of twine, lint from the bags, fine particles of leaves from the Java baskets and Philippine mats, are traceable to the opening of the containers in the melt house.

The process of removal is called defecation. In former years this was accomplished by adding bullocks' blood to the raw-sugar liquor in the blow-ups and heating the mixture until the scum which rose to the surface cracked, when the solution below was found perfectly clear, or, in the language of the refinery man, _bright_. Today, however, chemicals are the defecating agents, those most commonly used being phosphoric acid and lime. Phosphoric acid, neutralized with lime, throws down a heavy, flocculent precipitate which, as it settles, sweeps the solution and drags down all the suspended matter, gums, etc., leaving the liquor above clear and transparent.

The precipitate must now be removed, and this is accomplished by running the liquor through the bag filters on the floor below. These filters are tight iron boxes, about sixteen feet long, six feet wide and seven feet high. The top of the box is depressed about eight inches below the sides and ends, thus forming a tank. This top is perforated with five hundred holes, one and one-half inches in diameter. From the bottom of the iron box is an outlet pipe leading into tanks below.

In each of the holes on the inside top of the box is screwed a so-called "brass bottle," conical in shape, to which is securely attached a closely-woven cotton filter bag, about twenty-four inches wide and seventy inches long. This filter bag is encased in a heavier and stronger cotton sheath, or sleeve, about eight inches wide, which adds strength and keeps the twenty-four-inch bag in folds so as to give an effect similar to that of a folded paper filter, frequently seen in drug stores. Each bag filter contains five hundred of these bags, suspended vertically from the top.

Before any liquor is run on the filters, the bags and the iron box are heated by means of steam to bring the apparatus to a temperature of about 190 degrees Fahrenheit. This prevents the chilling of the sugar liquor by cold bags, which would cause the bags to become "blocked," as it is technically called. The liquor from the blow-ups, at 190 degrees temperature, is now turned into the depressed tank on the top of the filter and flows through the perforations into the bags attached on the inside, down through the bags, and finds an exit through the bottom of the filter into the tanks below.

As the first liquor comes through the bags, it is a little cloudy, but in a few minutes, as the pores of the bags fill with the insoluble substances, it becomes perfectly bright, all the suspended and insoluble impurities remaining in the bags, together with the precipitates drawn over from the blow-ups. The cloudy liquor is pumped to the top of the filter and clarified by being run through a second time. It is interesting to know that it is not really the bag that does the filtering, but the thin layer of sediment that is deposited from the liquor itself on the inner surface of the bag. The cotton bags are made in a particular manner, and from a fabric especially adapted to catch the sediment and to form, in conjunction with it, an excellent filtering medium.

[Illustration: BAG FILTERS—SHOWING BAGS IN PLACE]

[Illustration: FILTER PRESSES]

The liquor, as it runs into the tanks, must be carefully watched, for sometimes a bag inside the filter breaks, which causes cloudy liquor by allowing the precipitates to gain entrance into the clear liquor. As soon as this is noticed, samples are taken from the outlet of each filter and the defective one found and investigated.

When a bag is torn, or develops a hole, the liquor runs through the opening on the top of the filter so fast that it forms a little whirlpool, which shows the bag that is broken. A wooden plug is immediately driven into the opening and that particular bag cut out. The men on the bag filters soon become so expert that they detect broken bags and plug them before the cloudy liquor gets to the inspection station. It is essential that the liquor be freed from all suspended impurities at this station before the next step is taken, hence great care and watchfulness must be exercised.

In time the coating of sediment, gums and precipitates on the inside of the bag becomes so thick that the liquor runs very slowly and finally stops. The refinery term for this condition is "stuck-up." Depending on the impurities in the original liquor, the bag filters will continue to filter the liquor for from twelve to twenty hours and sometimes longer.

After the bags are "stuck-up," the liquor remaining in them is sucked out by means of vacuum through a small pipe attached to a long rubber hose and inserted in the bags through the holes in the top of the filter. The liquor thus sucked out of the "stuck-up" bags

is sent to the blow-ups and reprocessed with new liquor, thus beginning its journey anew.

As soon as the liquor is sucked out, hot water is run through to reduce the sugar contents of the filter. This water is saved and the sugar it takes up is subsequently recovered. The filter is then opened by means of an electric hoist traveling on an overhead track immediately above the filters. Chains are attached to the top of the filter and the hoist elevates top, bags and all, to a point sufficiently high for the bags attached to the top to clear the adjoining filters. The top and bags are then moved along the track to the washing station. Meanwhile another hoist has delivered a duplicate top, with fresh bags attached, to the filter, where it is lowered into place. In this way the filter is again in operation within five minutes. At the washing station the bags just taken from the filter are detached from the top for washing, and the top is sent to a point where clean bags are again attached. It is then ready to go into another filter.

At the washing station the dirty bags are pulled out of the sheaths and turned inside out in tanks containing water, thus releasing a large quantity of the impurities. The bags and sheaths are then thrown into washing machines, where all the remaining impurities and sugar are washed out of them. From the washers the bags are put into centrifugal machines, or through powerful wringers, and dried sufficiently to permit being rehandled. They are then resheathed and made ready to be attached to another top.

The water from the washers contains a large amount of sugar and is conducted to a tank similar to one of the blow-ups, where it is treated with lime and diluted with water at 190 degrees Fahrenheit until it contains only from ten to twelve per cent of solid matter. This liquid is then pumped through filter presses and the impurities removed. The “sweet water,” as it is termed, which now contains practically all the sugar, is collected in tanks and the sugar is ultimately extracted by evaporation, filtration and boiling to grain.

[Illustration: MAKING NEW BAGS AND LINING THE WASHED BAGS]

[Illustration: PRINTING THE EMPTY RAW-SUGAR BAGS]

The impurities removed by the filter presses consist of sand, portions of bags and baskets, phosphates, hair, lime, salts and gums, in fact every kind of foreign matter that finds its way into raw sugar either in the process of manufacture or in transportation. A small amount of sugar accompanies this refuse, but as its recovery would cost more than it is worth, it is allowed to run to waste. The filter-press cake, as it is called, contains valuable fertilizing agents, and when conditions permit it is used for fertilizing purposes, otherwise it is run to waste.

BONE-CHAR FILTRATION

REMOVAL OF COLOR

To resume the course of the bag-filtered liquor, from which the superficial, the suspended and insoluble impurities have been removed and which is now the color of clear amber, the next step is bone-char filtration.

Bone-char, bone-coal or bone-black, as it is variously called, is made from the bones of animals. After the fat and glue are removed, the bones are subjected to a dry distillation which carbonizes them. These charred bones are then broken into very small pieces, or until they will pass through a ten-mesh screen and remain on a thirty-mesh screen; in other words, the size of the grains used in a sugar refinery vary from one-tenth to one-thirtieth of an inch. If properly manufactured, the grains are hard, porous, and have a great affinity for moisture.

Bone-char has the peculiar property of removing from the sugar liquor, in some unknown mechanical way, not only the soluble salts but the coloring matter as well. The elimination of the salts and coloring matter facilitates the subsequent crystallization.

The char house is, therefore, by far the most important station in a refinery, for failure in the char house means failure throughout.

Contrary to the general practice in Europe, beet-sugar factories in the United States do not use bone-char, and consequently do not take all the coloring matter and salts out of the liquor. They secure a white sugar by other methods, which will be explained later on. In a cane-sugar refinery, however, the coloring matter and impurities are entirely eliminated, and the product is invariably pure and white.

The char filters are cast-iron cylinders, usually ten feet in diameter and twenty feet high, with doors at the top for entrance of the char and openings at the bottom through which it is removed. There are also many pipe connections for the introduction and outlet of liquors, steam, hot water and compressed air. The filters are insulated on the outside with asbestos or some other non-conductor

of heat to prevent the temperature of the liquor from being lowered as it passes through. Each filter has a capacity of from sixty thousand to eighty thousand pounds of bone-char.

At the bottom of the filter is a perforated iron plate. Over this is placed a coarsely woven cotton blanket, through which the liquor will pass, but which prevents the char from escaping from the filter with the liquor or wash water. After the blanket is set in place, the char is delivered by gravity through an overhead pipe into the filter, until it is entirely full. The char, as it goes in, has a temperature of from 170 to 180 degrees Fahrenheit, and the bag-filtered liquor which is then run on has a slightly higher temperature.

[Illustration: CHAR FILTERS]

[Illustration: CHAR FILTERS—SHOWING OUTLET PIPES]

When the liquor in the filter reaches the top and the char has settled in a compact mass, the cover is put on and fastened securely to prevent leakage. The liquor is again allowed to run into the filter by gravity, from the tanks about fifteen feet overhead. The valve on the bottom of the filter is then opened and the liquor, as it filters slowly through the char, is led through a copper pipe to the liquor gallery, to which station all the char-filtered liquor is delivered. This pipe, instead of leading downward from the filter, leads upward and nearly to the top, so that the flow of liquor through the char will be slow and uniform and the filter will always remain full of liquor. The diameter of the filter is ten feet, while that of the outlet pipe is two inches, so that the flow of liquor through the char is necessarily very slow. The reason for this is that the liquor must remain in contact with char a certain time to enable the char to absorb the coloring matter and soluble salts.

The first liquor from the filter appears cloudy and is sent back for refiltration, but it soon becomes bright, perfectly colorless and transparent as plate glass. This white liquor is pumped from the liquor gallery into the tanks on the top floor in the pan house, ready for the next process, which will be dealt with presently.

After a filter has been running for from twenty-four to thirty-six hours, depending on the character of the sugar in the liquor, the char becomes “tired” or spent. In other words, it has absorbed so much of the impurities and coloring matter from the liquor passing through it that its capacity to absorb more is gone and the liquor begins to show a slight straw or canary color. The inspector in the liquor gallery immediately notices this and orders the liquor stopped. Immediately afterwards a lower-grade liquor is turned into the filter, which forces the first liquor out before it. In due time the man at the liquor gallery notices the number two liquor coming from the filter and turns it into separate tanks. In time a still lower grade of liquor is turned on and the filter run until the bone-char is absolutely exhausted, when it is ordered “sweetened off.”

Hot water is then turned in at the top of the filter to wash out the remaining sugar liquor which gradually becomes more and more dilute. When its density has been lowered to about thirty-five per cent of solid matter, it is diverted to other tanks, and this is continued until only three-tenths of one per cent of sugar remains in the sweet water, as it is now called. The washing of the char in the filter in this manner, by hot water, is kept up for twelve hours, but as soon as the sugar content falls below three-tenths of one per cent the solution is allowed to run to waste, as the recovery of this small percentage of sugar would cost more than its value.

The sweet water is sent to the evaporators, concentrated to 58.6 per cent of solid matter, and it then begins its refining journey over again.

This long and continued washing of the filters is for the purpose of removing as much as possible of the organic and mineral impurities absorbed by the char.

The washing completed, compressed air is applied to the filter to force out the remaining water. The bottom doors of the filter are then opened and the char, containing about twenty per cent of water, drops to the floor below. Here it passes through mechanical driers and is delivered comparatively free from moisture to the kilns. There it is revivified, that is, the organic matter in the char which could not be removed by washing is converted into carbon by being heated to a cherry red in the absence of air. This is accomplished by allowing the char to pass by gravity through the red-hot retorts of the kilns.

As the wet char leaves the filter, it drops on a moving belt which carries it to large cast-iron hoppers leading to the driers immediately beneath, where the greater part of the moisture is expelled from the char prior to its being treated in the revivifying kilns. The driers are made up of a number of thin, hollow, cast-iron, triangular pipes, enclosed in a large, rectangular, outside casing. The wet bone-char passes over these hollow pipes as it falls slowly through the drier. The hot gases from the furnaces of the kilns below pass through these cast-iron pipes, giving off heat as they ascend, thus driving off the moisture in the char as it falls

down over the outer surface of the pipes. At the same time, hot air obtained from cooling the char in the cooling pipes below the retorts is drawn through the drier, coming in direct contact with the char. The moisture given off by the char is absorbed by this hot air and carried out of the drier and building by fans or smokestacks. By this means the water in the char is reduced to ten per cent, and in this comparatively dry, hot state it runs freely by gravity from the bottom of the drier into a second set of hoppers, through which it drops into the retorts of the kiln. The hot gases, after drying the char, pass out at the top of the drier through a flue leading to a stack outside the building.

[Illustration: TOP OF CHAR FILTERS—SHOWING PIPE CONNECTIONS]

[Illustration: EXTERIOR VIEW OF CHAR DRIER]

The kilns are large square boxes of brick, built around a strong supporting iron structure. On each side of these boxes are a number of large flat pipes of cast iron, nine feet long and twelve inches by three inches in section, the iron being three-quarters of an inch thick. These pipes are called retorts and are arranged vertically in the kilns, forty on each side. The space in the center between the retorts is known as the furnace and extends the entire length of the kiln, a distance of about sixteen feet. Intense fires are maintained in this central space and the flames playing around the retorts keep them red-hot. The upper ends of the retorts lead into the hoppers above and the lower ends to the cooling pipes below. As the char passes gradually through the red-hot retorts, it becomes heated to 900 degrees Fahrenheit and the organic matter it absorbed from the sugar liquor is changed into carbon. In this way the char becomes almost as good as new, or, as the term goes, revivified. Each kiln has a capacity of revivifying sixty thousand pounds of bone-char per day.

If the char in this red-hot state were suddenly exposed to the air, the contact with oxygen would bring about combustion and the char would be quickly reduced to ashes, so a cooling process is necessary. It is, therefore, drawn from the cast-iron retorts into cooling pipes located directly beneath. These pipes are of thin sheet-iron and are about three by four and a half inches in section. There are three under each retort, and a mechanical device at the bottom allows only a small amount of char to escape at a time. This amount can be regulated at will by the operator, and in this way the char is held in the retorts the exact time necessary for its revivification.

A current of cold air circulates continually around the cooling pipes, taking up the heat from the char and delivering it through pipes to the drier overhead, so that when the char leaves the bottom of the pipes its temperature is about 180 degrees Fahrenheit. From the cooling pipes, it drops on a belt conveyor from which it is carried by endless belt or chain bucket elevators to the top of the char filters to be used again.

The manipulation of the char filters varies in different refineries, some running the liquor over the char for a longer period than others, but a fair average of the time required for filling, settling running liquors and syrups, sweetening off, washing, applying air and emptying, is eighty-six hours, the shortest time being seventy-two hours. Taking eighty-six hours as a basis, it will be seen that the char is handled and revivified eighty-one times each year after making due allowance for Sundays, holidays and annual clean-up periods.

Each time the char is handled, a certain amount of it is broken into dust, and this is taken out by passing it over fine screens, and also by exhaust fans. Obviously, the amount of dust taken out each day must be replaced by its equivalent in new char. It is estimated that the original char put into the filters will last from five to six years before it finally becomes disintegrated and is taken out as dust.

[Illustration: INTERIOR ARRANGEMENT OF CHAR DRIER]

[Illustration: EXTERIOR VIEW OF CHAR KILNS—SHOWING OIL-BURNING APPARATUS]

As approximately one pound of char is required for every pound of sugar melted, it will be seen that as the liquor is in contact with the char for only twenty-four hours out of seventy-two, a refinery turning out two million pounds of sugar per day should have filter capacity for six million pounds of char. The amount of the latter that is handled each year is, therefore, very great and requires a large and costly plant to take care of it properly.

CRYSTALLIZATION

PRODUCTION OF CRYSTALS BY CONCENTRATION

The refining process has been described up to and including the purification and decolorizing of the sugar liquor, the last step being the delivery of the pure white liquor into the receiving tanks in the pan house.

After the white liquor leaves the char filters, the greatest care must be exercised to keep all the machinery, piping and apparatus scrupulously clean, for if any foreign matter becomes mixed with the liquor or sugar it can only be removed by refiltering or remelting.

By means of vacuum, the liquor is drawn from the tanks into the vacuum pans, this being the last operation in which the sugar is handled in a liquid state. From this point on it drops by gravity from floor to floor in a solid or semi-solid form, until it reaches the packing room as a finished product. In a first-class refinery, the vacuum pans, as well as all the piping through which the liquor passes, are made of copper instead of iron and steel, which eliminates the possibility of rust or scale getting into the sugar.

Refinery vacuum pans are usually from fourteen to sixteen feet in diameter and from sixteen to seventeen feet high, while in shape they appear almost spherical. The boiling takes from one hour and twenty-five minutes to one hour and forty-five minutes, and about forty-five tons of granulated sugar can be made at each boiling in a fourteen-foot pan. Before the liquor is drawn in, the pan is thoroughly cleansed with hot water and steam. All openings are then closed and the vacuum pump started. The air is quickly exhausted, a valve in the pipe line leading from the receiving tank is opened and the pan is given a charge of liquor. Steam is turned into the coils of the pan and the boiling process begins. Soon sufficient moisture is driven off to cause the sugar to “grain.” Shortly after the grain forms, another charge of liquor is drawn into the pan and the operation is repeated until the pan is full of a thick, white, mushy substance called massecuite, that looks very much like half-formed ice. The vapor driven off in the boiling passes out through a large pipe at the top of the pan and is condensed by being sprayed with cold water. On account of the high vacuum, the liquor boils violently at temperatures ranging from 140 degrees to 195 degrees Fahrenheit; thus the risk of scorching, discoloration or caramelization of the sugar is minimized.

On the front of the pan is a vertical row of windows made of heavy plate-glass, and through these the liquor is watched during the boiling. The massecuite in the pan is sampled at intervals by the sugar boiler, by means of a “proof stick,” a brass rod about three feet long and one and one-quarter inches in diameter, in the pan end of which there is a hollow space. This stick is pushed through an opening in the side of the pan into which it fits tightly, and then partly withdrawn. A small quantity of the contents of the pan remains in the hollow space, and this the sugar boiler removes and places on a piece of clear glass. On holding it up to the light, he sees exactly how the crystallization of the sugar is progressing, and by observing and feeling the crystals, he is enabled to control the boiling perfectly. When he concludes that the evaporation is complete and the massecuite of the proper consistency, the pump is stopped and the vacuum broken by opening a valve near the top of the pan, admitting the outside air. The foot valve is then opened and the massecuite drops from the pan into a mixer directly underneath. There it is kept constantly in motion by a revolving shaft with paddles, to prevent the crystals from sinking to the bottom. From the mixer it is drawn into the centrifugals and purged of the mother liquor, the pure crystals being left in the machine. The liquor thus drawn off contains whatever impurities may have remained in the original liquor. It is now pumped back and run through the char filters again, after which it is boiled in the vacuum pan and the granulated sugar taken out in the centrifugals. This completes the process of producing crystallized sugar by concentration.

[Illustration: A REFINERY VACUUM PAN AND PUMP]

[Illustration: ARRANGEMENT OF STEAM COILS IN A VACUUM PAN]

There are many interesting and intricate problems in connection with the extraction of the sugar from the wash waters, sweet waters and low-grade syrups that are constantly accumulating in a sugar refinery, but space will not admit of their being dealt with here. Suffice it to say that the process of extraction is carried to a point where the sugar recovered barely pays for the labor and fuel expended in the operation. The ultimate result is white sugar, table syrup and molasses.

This molasses is used largely in the manufacture of vinegar and alcohol. Mixed with grain and alfalfa meal, it makes an excellent stock food that cattle take to readily and that possesses high value as a fattening agent. The sucrose and glucose content of molasses as it leaves the refinery is about fifty per cent.

Naturally, in a process involving so much handling, filtering and boiling, there must be some loss, and the efficiency of a refinery is based upon the percentage of granulated sugar recovered from the raw article delivered to the melt. It may be stated for general guidance that, taking an average of the refineries of the United States, one hundred pounds of refined white sugar is made from

each one hundred and seven pounds of ninety-six-degree raw sugar melted. Some of the sugar lost is accounted for in the molasses, in the sediment from the filter presses, and in the wash waters from the char filters. The remainder is the undetermined loss in handling, in sugar destroyed by heating, and in sugar dust escaping during the manufacturing operation. As has been said, the component parts of raw sugars vary more or less, and the recovery in white sugar from two lots of raws, each polarizing ninety-six degrees, might differ considerably according to the refractory matter in the original raw sugar.

The following figures give a fairly accurate idea of the disposition of one hundred pounds of ninety-six-degree raw sugar in refining:

Water, which is eliminated .70 per cent Non-sugar, which is eliminated 3.30 ” Sucrose loss, undetermined .75 ” Sucrose left in molasses 1.75 ” Sucrose extracted in granulated form 93.50 ” ------ Raw sugar melted 100.00 ”

The undetermined loss includes every loss from the time the raw sugar is weighed into the warehouse until the granulated article is sold to the buyer. It is evident, therefore, that one of the principal items of refining cost is the actual loss of weight in converting raw into refined sugar. Assuming that the raw sugar costs four cents per pound, the refiner has lost on each one hundred pounds melted, four cents × 6½ pounds, or twenty-six cents, less the small value of the resulting molasses. If the raw sugar cost six cents, the loss would be thirty-nine cents. At four cents, the loss is equivalent to $5.20 per ton, or, in the case of a refinery melting two million pounds of raw sugar daily, $5,200.00 for each working day. This does not include any of the operating expenses, such as labor, fuel, bone-char, containers, selling expense or administration—just the actual value of the raw sugar lost in the process of refining.

[Illustration: REFINERY CENTRIFUGAL MACHINES]

[Illustration: EXTERIOR VIEW OF SWEATER]

PARTIAL DRYING

PURGING CRYSTALS FROM THE SYRUP

Returning to the sugar left in the centrifugals, the force developed in a machine forty inches in diameter, spinning at the rate of eleven hundred revolutions per minute, is so great that it quickly dispels all the liquor surrounding the crystals, leaving them nearly dry, in a solid, vertical wall. Water, filtered to insure its purity and cleanliness, is then sprayed on this spinning wall of sugar, only to be immediately thrown off through the sugar by the centrifugal motion. In passing through the sugar it washes the last of the syrup from the grains and leaves them perfectly white. Cold water, rather than hot, is used for this purpose, as it dissolves less sugar.

In former years a small quantity of bluing was added to the spraying water in order to enhance the whiteness of the sugar, just as bluing is employed in washing fine linen fabrics. Since the pure-food laws became effective, however, the practice has been discontinued in all cane-sugar refineries.

After the sugar is thoroughly washed, the centrifugal machine is stopped, a large valve in the bottom opened and the mechanical discharger rapidly ejects the sugar (now containing only about 1.2 per cent moisture) from the machine into a storage bin beneath.

FINAL DRYING OF CRYSTALS

For some reason not well understood, the next step in refining is called “granulation.” Actual granulation, or crystallization, takes place in the pans, and the process about to be described should properly be called drying. The manufacturing term, however, is as given.

Drying is effected in an apparatus consisting of two large cylindrical drums of wrought iron. These drums are about six feet in diameter, thirty feet long and have a slight downward pitch from the receiving to the discharging end. The first drum rests on the floor, directly below the storage bin, and is called the sweater. It turns slowly on revolving wheels, by means of circular tracks bolted to it. The power that moves it is delivered from an electric motor, through a pulley, shaft and pinion, the latter working in a gear bolted to the outside circumference of the drum. Fastened to the inner surface of this drum is a series of short, narrow shelves with saw-tooth edges that serve to carry the sugar to the top of the revolving cylinder, whence it falls to the lower side, causing a continual shower of sugar throughout the entire length and breadth of the drum. The sugar is delivered through a pipe at the upper end of the sweater, and the revolving motion together with the incline of the cylinder gradually works it down to the lower end. Here it drops through a chute to the granulator on the floor below, where the process of drying is completed.

A strong current of hot air is drawn through the sweater by a powerful fan connected to the upper end by a very large pipe. The air introduced in this way is brought to a high temperature by passing around a number of coils of pipe charged with steam, which are placed directly in front of the sweater. The hot air sweeping through the drum absorbs nearly all of the moisture in the sugar, which carries 1.2 per cent of water when it enters the drum and about 0.1 per cent as it leaves it.

The granulator, or lower drum, is the same size as the sweater and is constructed in very much the same manner, having shelves for carrying the sugar to the top and dropping it at the proper point, and being equipped with a large fan to draw off the hot, moist air. Instead of having steam coils in front, however, it has in its center a steam-heated drum about twenty-four inches in diameter that revolves with it. The sugar crystals, as they fall in a shower from the shelves, come in contact with the hot inner drum on their way through the granulator, and in this manner become thoroughly dried. The moisture in the sugar, as it emerges from the granulator, is less than four-hundredths of one per cent, an amount too slight to determine except with the most delicate apparatus.

[Illustration: FRONT VIEW OF SWEATER—SHOWING STEAM COILS FOR HEATING THE AIR]

[Illustration: INTERIOR VIEW OF SWEATER]

To insure perfect drying, the damp sugar must be fed to the upper drum or sweater with unfailing regularity. This is accomplished by the use of revolving screws located under the storage bins. By turning a certain number of revolutions per minute, they deliver an even and steady supply of sugar.

From the granulators the sugar is dropped on thin cotton belts that, passing around highly magnetized pulleys, carry it to the dry storage bins. The sugar is cooled to normal temperature before being packed in containers, thus preventing subsequent absorption of moisture and consequent caking.

Magnetic pulleys are used to extract any particles of iron scale or rust that may drop into the sugar after the liquor leaves the char filters. Rust sometimes forms in the pans, mixers, conveyors, elevators, sweaters or granulators, and should it get into the sugar the magnetic pulleys will surely remove it.

Storage bins and storage tanks are prominent accessories of all sugar refineries, for if a breakdown should occur at any point, there must always be a supply of material on hand to keep the refining operations going while the trouble is being remedied.

SCREENING

SEPARATING CRYSTALS INTO VARIOUS SIZES

The now thoroughly cold, dry and free-running granulated sugar is drawn from the storage bins through galvanized metal pipes and taken to the separators by screw conveyors, which deliver it at an even, steady feed—a most essential feature. The sugar as it comes from the pans is made up of crystals of various sizes. It also contains a number of small lumps formed in the centrifugal machines, or in some part of the process after it leaves the pans. It is necessary to separate the crystals according to size and to screen out the lumps, for the following reason:

In some parts of the country, people have been educated to use a coarse-grained sugar; in other sections, they are accustomed to sugar of a fine grain. For example, on the Pacific coast, the demand is for the fine-grained article; the consumers of the Mississippi river valley like a fairly large grain; while the Atlantic coast trade calls for a still coarser product. There is a difference, too, as to containers. In the East the preference is for the barrel package, while the Western buyer wants his sugar put up in bags.

There are many different types of separators commonly in use, but in all of them the governing principle is the same. It is the elimination of lumps and dust from the final product and the separation of the sugar crystals according to size. The separator here specifically referred to will explain the principle as well as any other type, and a glance at the accompanying illustration will give the reader a good idea of its construction. It is made up of a number of wire screens of various sizes, fixed at a sharp incline, one above the other, and all enclosed in a tight, dust-proof steel case. At the top of the case is a steel screw conveyor by which the sugar is fed evenly and steadily across the entire width of the top screen.

On the outside face of the case are a number of shafts to which hammers are attached. As the shafts revolve, the hammers tap the various screens below, lightly and at rapid intervals, thus causing them to vibrate.

[Illustration: SEPARATOR—CLOSED, READY FOR OPERATION]

[Illustration: SEPARATORS, ONE OF WHICH IS OPEN—SHOWING THREE SCREENS FOR SEPARATING THE SUGAR GRAINS]

The upper screen, called the scalper, is quite coarse and allows all the sugar to fall through except the lumps, which run down the face of the screen into a pipe that carries them to the melt, where they begin the refining process over again. These lumps, however, represent a very small proportion of the whole.

The second screen is finer than the scalper. It permits part of the sugar to pass through, but retains a certain amount which falls down on the face of the screen, whence it is led through a pipe to a special bin. Sugar of this size is known as coarse granulated.

The next screen lets the finer grains drop through, but catches the standard granulated, which in turn is drawn off to its special bin. The last screen, an extremely fine one, retains the extra fine granulated, and this in turn is delivered to its appointed bin. The sugar passing through the last screen is so fine as to be classed as “dust,” which, not being marketable, is usually remelted.

The amount of any one grade of sugar obtained from the separator may be changed, within certain limits, by the boiling in the vacuum pans. If a large proportion of fine-grained sugar is required, the sugar boilers are instructed accordingly. It is impossible, however, to boil all the grains in each strike a uniform size, or to boil any two strikes exactly alike, so the separators are necessary, especially for removing the lumps and dust. The dust is caused by the constant falling of the dry sugar crystals against each other in the driers and granulators, and by the grinding action upon the sugar crystals in the screw conveyors.

PACKING

FILLING VARIOUS KINDS AND SIZES OF CONTAINERS

When putting up his goods, a sugar refiner—like every other manufacturer—must needs cater to the wishes and tastes of the consuming buyer. The modern tendency in containers is in favor of sealed air-tight and dust-proof packages. Some refiners spend great sums of money every year in advertising the merits of special sugars packed in dust-proof cartons. Their rivals generally follow suit, as competition in the marketing of sugar is probably far keener than in any other line of business.

The plain truth is that all refined granulated cane sugar offered for sale in the markets of this country today is almost identical, irrespective of the manner in which it may be packed. The poorest quality of refined sugar made has, in all likelihood, a purity not lower than 99.5 per cent, while the highest grade cannot possibly exceed 99.9 per cent, a difference of only four-tenths of one per cent, hence it is evident that all refined sugars are practically pure, the fancy package simply meaning a fancy price.

The methods of transporting and handling the sugar after it leaves the refinery may justify the additional expense, but this is subject to argument. However, it makes but little difference to the manufacturer, as the cost of the package as well as the extra handling is always included in the selling price.

A few years ago all sugar went out in barrels or bags, while today a modern refinery turns out about twenty different styles of container, and twenty-four kinds of sugar. It is obvious, therefore, that the packing room of a refinery is an interesting place, covering as it does a large area and including a great amount of special, intricate machinery for filling, weighing and sewing or sealing packages.

In the bottom of the bins into which the sugar is delivered from the separators is a series of galvanized iron pipes, through which the sugar runs to the various filling devices, the latter being usually arranged in long rows. Under the end of each pipe is an automatic weighing machine. In packing bags, a workman hangs a bag on the weighing machine and presses a lever, thus allowing the sugar to run into the bag. As soon as the exact amount required is reached, the flow is automatically cut off. These weighing machines are so accurate that they gauge the amount to within a fraction of an ounce. The operative removes the full bag, places it on a conveyor that runs in and level with the floor and quickly adjusts an empty one on the weighing machine. These men become so expert that a single operative will fill two hundred and fifty one-hundred-pound bags per hour. The weighing machines are designed to fill and weigh four hundred and eighty one-hundred-pound bags per hour, but the operative cannot handle them at this rate.

[Illustration: FILLING, WEIGHING AND SEWING 100-POUND SACKS]

[Illustration: FILLING, WEIGHING AND SEWING 25-POUND SACKS]

Four sewing machines, specially designed for sewing the filled bags, are located immediately over the conveyor and in direct line with it. As the bag passes along on the conveyor, the operative at the first machine picks up the end of the inner cotton sack and passes it through his machine, stitching it securely. The bag then passes along to the third machine, where the operative takes hold of the outer burlap bag and sews it in the same manner. Each operative has a spare machine ready for instant use in case the one he is running gets out of order. Continuing its journey to the end of the conveyor, the bag is deposited on the main belt conveyor, which takes it without manual aid to the shipping floor or the storage warehouse. A sewing-machine operative will sew as many as seventeen bags per minute, but it is trying work and the men relieve each other at intervals during the day. Both the one-hundred- and the forty-eight-pound sacks are handled in this manner. Formerly the half sacks weighed fifty pounds, but since the Parcel Post law went into effect they have been changed to forty-eight pounds to permit of their shipment by mail. Those containing twenty-five, ten, five and two pounds are weighed and sewed in much the same way, by the aid of specially designed, rapid-handling machinery. The small package machines will accurately weigh and fill five-pound bags at the rate of twenty-five packages per minute, the others in proportion.

The paper boxes, or cartons as they are called, are weighed and filled by special machinery. This machinery seems to possess an intelligence almost human. One girl feeds the cartons (the tops and bottoms of which are open) into the machine at the rate of thirty-two per minute. The machine glues the bottom, weighs the sugar to within one thirty-second of an ounce, fills the carton, glues the top, seals it and passes it on to a conveyor which delivers the finished package to a table, from which it is packed into a box for shipment. Women are usually employed in putting up the lighter packages.

A short distance from the bag-weighing machines, and running parallel with them, is a line of pipes or spouts for filling barrels. On the floor under each spout is a barrel shaker. This is a heavy cast-iron plate that is lifted about one inch, first on one side, then on the other, by the action of two cams or arms attached to a revolving shaft underneath. The shaker drops back violently on the supporting frame after each lift, causing the sugar to settle compactly in the barrel as it is filled to an average weight of three hundred and fifty pounds. Naturally, the greater the amount of sugar packed in a barrel, the less the container costs per unit of output, and as the average cost of a sugar barrel in the United States is fifty cents, the container cost per one hundred pounds of sugar is 14.3 cents.

Without the shaker, not more than three hundred and thirty pounds of sugar could be put in a barrel, which would increase the cost per one hundred pounds to 15.1 cents. This difference on a single day’s output of two million pounds represents one hundred and sixty dollars, an eloquent argument in favor of the shaker.

[Illustration: FILLING BARRELS]

[Illustration: METHOD OF HANDLING BARRELS]

In packing barrels, the operative first lines the barrel with heavy paper to prevent the sugar from coming in contact with the rough wooden sides and to keep it from sifting out between the staves. The barrel, thus lined, is placed on the shaker, a valve on the spout opened and the shaking barrel filled to the top. The barrel is then removed and turned over to the cooper, who heads it up and rolls it on the scale for weighing.

Before an empty barrel reaches the packing room, it is weighed and the weight (generally from nineteen to twenty-five pounds) is stamped on its side. The gross weight of the filled barrel is determined by the packing-room scales. The weight of the empty barrel is deducted and the net weight of the sugar stenciled on the head. The full barrel is then sent down a chute to the waiting freight car or to the dock for steamer shipment, or to a conveyor that automatically delivers it to the storage warehouse.

In addition to the bags, barrels, half barrels, cartons and boxes, tins of various sizes are used for the different sugars. All of these are filled and weighed automatically, and taken from the packing room by conveyors. Some of the boxes are lined with paper and some with cotton cloth; some are nailed up in the ordinary way, and others are strapped with iron at each end. As a rule, the individual tins are cased with wood, but sometimes there are a number of tins in a case. Cartons contain two pounds, three pounds or five pounds of sugar. They are packed in fiber cases holding thirty twos, twenty threes or twelve fives and also in wooden cases which hold sixty twos, forty threes or twenty-four fives each. The style of package depends upon the demand of the trade catered to.

At this point a word or two about some of the specialties, such as cube, powdered and bar sugars, as well as yellow or soft sugars, may be of interest.

CUBE SUGAR

The sugar from which the cubes are made is of a rather fine grain, boiled in special pans from liquor that has been filtered over the char at least twice. From the centrifugals under the pan it falls into a hopper in which there is a revolving screw. Directly over the screw is a tank containing a warm, white sugar liquor, very sticky and viscous by reason of its density. A pipe leads from the bottom of this tank to a point over the screw, and the liquor, which is controlled by a valve, is allowed to drip upon the sugar. The action of the screw causes the sugar and the liquor to become thoroughly mixed and feeds the damp mass thus formed into a spout leading to the cube press, the machine in which cube sugar is made.

At the top of this machine is another hopper, into which the damp sugar drops from the spout overhead, and revolving in the last-mentioned hopper are a number of small shafts with brass pegs inserted at certain intervals along the length of the shafts, like spokes in the hub of a wheel. These pegs are like human fingers in their action and they press the sugar down into the pockets of a large revolving drum placed directly under the hopper. Each pocket is the size of a cube or half cube. Working in these pockets are plungers, which fall back as the revolving drum reaches the highest point directly under the mechanical fingers in the hopper. The fingers fill the open pockets and, as the drum turns, the plungers, at a certain point in its circumference where a heavy bronze bar is placed across its face, slowly enter the pockets and in so doing compress the sugar into cube form.

Two belts run through the machine under the cylinder, carrying galvanized iron plates about twenty-four inches wide, or the same width as the cylinder, and thirty inches long. As the line of pockets into which the sugar has been pressed reaches the lowest point on the circumference of the drum, the plungers drop down, forcing the pressed cubes out of the pockets onto the galvanized iron plates which the moving belt carries along out of the way of the next lot coming from the cylinder. Each plate, as it leaves the cube press, contains five hundred and four cubes and one hundred and sixty-eight half cubes, and the time required to fill a plate is between six and seven seconds.

[Illustration: CUBE-SUGAR MACHINE]

[Illustration: CARTON MACHINE]

The belts carry the plates to a series of ovens, or driers, so placed that a large number of plates with their contents may be inserted through a door on the belt side. When the ovens are filled with plates holding the soft, moist cubes, a current of hot air is turned on at the top of the ovens, passing out at the bottom. The hot air circulating in this manner dries the cubes and carries off the moisture. Eight hours in the ovens suffice to render the cubes thoroughly dry and hard. They are then removed through doors opposite to those through which they were put in. This arrangement prevents the men who are putting the cubes into the ovens from interfering with those taking them out, for the process is a continuous one and cubes are placed in and removed from the ovens at the same time. As the cubes are taken out of the ovens, they are deposited on a belt conveyor which delivers them into bins in the packing room, ready to be put into boxes, bags, barrels and other containers.

POWDERED AND BAR SUGAR

Powdered and bar sugars are made by grinding coarse granulated sugar into fine particles and then separating these particles by screening them through fine silk cloth. The bolting of flour is a similar process. Powdered sugar has a decided tendency to cake and become hard, and the coarse sugar from which it is ground should be particularly free from moisture. After being crushed or ground between corrugated rolls turning at high speed, the ground sugar passes into a screening or sifting device, of which there are many kinds in use, the most common being the horizontal, revolving centrifugal screen. The crushed sugar goes in at the head end, and, as it enters, a number of revolving arms throw it against a silk screen on a circular frame, revolving in an opposite direction, that permits the finest, or powdered, sugar to pass through a silk cloth having over sixteen thousand openings per square inch.

The powdered sugar extracted, the remainder drops into another screen where a similar sifting action takes place, the silk of the second screen being coarser than that of the first, and bar sugar is the result. Such grains as are too large to pass through the bar screen are carried back to the rolls and reground. The bar screen has about five thousand openings per square inch.

Bar sugar, as the name implies, is generally used in preparing beverages. It dissolves almost instantly when dropped in water. Singularly enough, the average housewife is not aware of the advantages attending the use of this grade of sugar. It does not become caked as readily as powdered sugar does, and is the ideal sweetening for berries and cereals served at the breakfast meal. It is far more desirable than powdered sugar for most of the purposes for which the latter is commonly used.

It is believed by many that _all_ powdered sugar is adulterated with chalk, starch, white corn meal or similar substances. Such is not the case, and it is safe to assume that no mixing whatever is done by any refiner in America. Powdered sugar has a strong tendency to cake or become hard, and some manufacturers who buy coarse granulated sugar from the refiners for grinding purposes use starch to the extent of from two to three per cent. Chalk is never used, nor are other non-edible or deleterious substances. Starch is not introduced for the purpose of making a greater profit, but to prevent the powdered sugar from caking. The adding of starch, in all probability, increases the cost of making powdered sugar, as starch costs almost as much as sugar, and the expense of handling it and feeding it into the grinding machinery is quite an item.

[Illustration: FILLING, WEIGHING AND SEWING 2-POUND, 5-POUND AND 10-POUND BAGS]

YELLOW SUGARS

Yellow sugars, or “softs” as they are usually called, comprise fifteen grades, ranging in color from a creamy white to a dark brown. These sugars are used chiefly by bakers in making gingerbread, pies and cakes, although a small quantity finds its way directly into households for ordinary domestic consumption.

The characteristics of yellow sugars are that they have a small grain and contain a sufficient amount of molasses to make them moist to the touch, properties brought about by a radically different method of boiling from that applied to white sugars. They also contain a certain amount of invert sugar which preserves the softness of grain and prevents subsequent caking or hardening.

To properly explain how yellow sugars are boiled, reference must be made to the method of boiling white sugars, which may be briefly summarized as follows:

The object to be attained in boiling white sugars is the separation of the crystallizable sucrose contained in a given solution from the impurities, moisture and non-crystallizable content of that solution. The formation of sugar crystals is a natural result of the evaporation of the moisture from the liquor or solution. In order to obtain pure white crystals, it is vitally essential that, as far as possible, all impurities and non-sugars, except water, be removed from the liquor before the boiling takes place, for if the coloring matter is not thoroughly taken out, obviously the crystals will be colored. The purifying and decolorizing operation is accomplished in the char filters. After the grain is once formed in definite crystals, these crystals attract and appropriate the sucrose in solution in the process of building up their structure, while repelling or excluding the impurities, so that in consequence the latter remain in solution. Irrespective, however, of whether crystallization of sucrose takes place in solutions of high or low purity, it will only partially remove the sucrose from the solution in one operation, the limit being fixed by the amount and nature of impurities present. In order to bring about further crystallization of sucrose the solution or mother liquor surrounding the crystals must be separated from them and be again diluted, filtered and concentrated.

Briefly, the procedure in boiling white sugar in a vacuum pan is to take liquors of the highest purity for the first boiling. After the first crystals have been removed from the mother liquor in the centrifugal machines, the liquor is again diluted, decolorized by bone-char and boiled to grain. This operation is continued a number of times, the purity of the liquor decreasing each time. Finally, when the purity of the liquor falls to a certain point, the boiling is discontinued, for at this point conditions do not admit of further formation of pure sucrose crystals, and, if the process were pursued further, the resulting sugar would not be white. Therefore, when this state is reached, these low-grade liquors are boiled into a semi-refined sugar, commonly called “refinery raw,” which corresponds fairly closely in test with the original raw sugar, or they are used for making soft yellow sugars as explained later on. This refinery raw is then washed, melted and put through the whole process all over again. The liquor, from which the crystals formed in repeated boilings have been removed as made, at length becomes so charged with impurities that further crystallization of sucrose is impossible and this residue, or final waste, is known as blackstrap molasses.

This manner of boiling white sugar has been called the “out and out” method, in contradistinction to the “in and in” method employed in boiling soft yellow sugars, of which a few words of explanation now follow.

In boiling soft yellow sugars, the aim is to produce a large number of small sucrose crystals having the property of attracting and combining with the molasses content of the liquor and that will retain some of the molasses after they are purged of mother liquor in the centrifugal machines. This process gives a sugar that may be described as a mechanical mixture of sucrose, invert sugar and the non-sugars in the molasses.

In the case of yellow sugars, the lighter the color the better price they bring. The greatest profit, therefore, is derived from the manufacture of sugars of the lightest color and carrying a reduced percentage of sucrose. In boiling such sugars, low-purity liquors from which the coloring matter has been removed as far as practicable by bone-char filtration are required. For the purpose, it is generally found most advantageous to use the liquors taken from white sugar massecuite at the point when, owing to repeated boilings, its purity has fallen so low that further extraction of pure white sucrose crystals is impossible.

As a result of the numerous filtrations through bone-char preparatory to reboiling in the manufacture of white sugar, these liquors are usually lighter in color than any of corresponding purity obtained in the refining process. Nevertheless, they are not necessarily the only liquors suitable for the purpose, and this particularly applies to the making of the lower grades of yellow sugars. It is, however, beyond the scope of this book to elaborate upon that phase of sugar refining. The object sought here is to give a general idea of how yellow sugars are boiled, without going into all the details.

As is the case with white sugars, yellow sugars are made by a succession of boilings in vacuum pans, the liquor used for each boiling or strike being that obtained from the massecuite of the previous strike. The operation is continued until the liquor becomes too low in purity and dark in color. Each successive strike boiled is lower in test than the preceding one, due to the fact that the sucrose crystals represent the purest part of the massecuite, and, consequently, each time they are removed the quality of the liquor is lowered. This accounts for the various grades of yellow sugar that are made, fifteen in all, starting with a creamy white and ending with a dark brown. The sucrose content of the best is about 92 per cent and that of the poorest about 80 per cent.

In making white sugars, the aim is to produce from liquors of high purity sucrose crystals that are pure white, hard and absolutely free from molasses.

In making yellow sugars, the object is to boil from low-purity liquors soft sucrose crystals that possess the property of attracting and retaining the molasses and to make this combination of crystals and molasses as complete as possible.

The essential difference between the two methods, as well as the appropriateness of the descriptive terms “out and out” and “in and in,” will be readily apparent.

The impurities in yellow sugars are natural and consist of invert sugar, glucose, organic non-sugars and salts, all of which were originally present in the raws or were formed in the process of refining.

It is not unusual to hear it said that yellow sugars are sweeter than granulated. To the average palate this is apparently so, but, as has been shown, granulated sugar contains 99.8 per cent of sucrose or sweetening matter, while the highest grade of yellow carries only 92 per cent. Soft sugars dissolve more readily on the tongue than granulated, and the syrup or molasses in them accentuates their sweet taste.

There are several other grades of sugar prepared for the consuming market, but lack of space precludes a description of them or the methods by which they are produced.

MECHANICAL DEPARTMENT

It is needless to say that the conveying, melting, filtering, boiling, drying, screening, weighing and packing of one thousand tons of sugar in twenty-four hours necessitates a great amount of steam and a multiplicity of machinery.

The boilers generate steam to drive huge pumps that deliver cold salt water to the condensers throughout the refinery, to drive vacuum pumps that make boiling and evaporation _in vacuo_ possible, and to drive large turbine or reciprocating engines that supply the electric power. The exhaust steam as it leaves the cylinders has a pressure of about fifteen pounds per square inch. It is conducted through pipes to the evaporators, pans, driers and tanks, where it is again used for concentrating the liquors, boiling in the pans, drying the sugar and keeping the liquors hot throughout the process. It leaves the various heating coils and tubes as hot water and is returned to the boilers for the generation of more steam.

Live steam, that is to say, steam just as it comes from the boilers, is used extensively in the vacuum pans for boiling the liquor to grain.

A refinery melting one thousand tons of raw sugar each day requires about 5500 boiler horse power. On the Atlantic coast coal is the fuel used, while on the Pacific coast oil is burned. The amount of fuel consumed in different refineries varies to some extent, but a fair average per ton of raw sugar melted is one and one-third barrels of oil, or one-third of a ton of coal.

In modern plants all the moving machinery, except the pumps and main engines, is usually driven by electric motors. This does away with many dangerous belts, as well as expensive transmission machinery. The motor drive is simple and efficient and therefore used extensively.

The mechanical department is under the general supervision of the superintendent, but in direct charge of a mechanical-electrical engineer. This man is known as the chief engineer, and he is directly responsible, not only for the operation of all the machinery in the plant together with its upkeep and repair, but he has also to cope with engineering problems that are constantly arising. Under his direction, a corps of draughtsmen is always busily engaged in planning and designing improvements and additions. He also maintains a force of mechanics, watching, operating and repairing the machinery. These men represent almost every trade, including machinists, blacksmiths, coppersmiths, tinsmiths, millwrights, boilermakers, riggers, masons, painters and many others.

The diversity of the mechanical work around a refinery is remarkable, and the engineer in charge must be a man of exceptional mechanical ability, as his duties include not only steam, electrical and civil engineering, but construction engineering of an advanced character. As refineries are always built on sites bordering on deep water, harbor engineering problems are also constantly before him.

In connection with every refinery there are many shops, where mechanical work incidental to repairs and construction is carried on. These shops are equipped with the necessary tools and implements for quick repairs and are under the supervision of the chief engineer. In addition, there is the cooper shop where many thousands of barrels are turned out daily, and the bag factory where twenty cotton bags and twenty burlap bags must be made for each and every ton of output packed in that manner.

The mechanical department of a modern refinery is as important as it is extensive, for failure in any one of its branches means costly delays. The machinery is run twenty-four hours each day, except Sundays, during about eleven months in the year. The plant is closed down the remaining thirty days for annual cleaning and repairs.

Intelligence and ability, tempered with good judgment, bring about the _esprit de corps_ that gives the necessary results. The mechanical is almost as important as the chemical department and, as before stated, it is subject to the general supervision of the chemical engineer.

[Illustration: LABORATORY]

[Illustration: OIL-BURNING BOILER PLANT]

LABORATORY

The chemical laboratory is really the heart of the institution, for upon it depends the success of every manufacturing operation. The superintendent of a refinery must possess a thorough knowledge of chemical engineering, for the process of sugar refining is largely chemical from beginning to end.

Competent chemical engineers, as distinguished from chemists, are rare, and yet their calling offers more promising prospects to young men than most other professions do today. It is clear to the intelligent observer that in these times of intensely keen competition, the manufacturer will, sooner or later, inevitably be driven to seek a considerable percentage of his profits in the utilization of by-products that now go to waste or bring but little return. The men to solve the manufacturing problems of the future will be chemical engineers. Broadly speaking, comparatively little has been done in this field in the United States, and its possibilities are incalculable.

In the laboratory, day and night, a corps of chemists is constantly engaged in the study of questions that arise in connection with the operation of the various departments. Polarizations for account of buyers and sellers of all raw sugars purchased, are made and checked there; hundreds of samples of liquors and syrups are tested daily for control work, as the purity of both must be known at all times and a record kept of their temperatures and densities. Samples of all the sugars entering the refining process, as well as of the finished product, are carefully analyzed, and upon these analyses are based elaborate calculations regarding yield and efficiency. The wash waters from the char filters are examined and tested frequently, the bone-char is tested every twenty-four hours as a check upon the process of revivification in the kilns, and once a month the bone-char is completely analyzed to determine the deterioration that has taken place in it.

Tests are made of materials used in the refining process, such as lime, soda, acids and lubricating oils; of the feed water for the steam boilers; of the fresh water used throughout the plant; and of the fuel, whether coal or oil. Even the gases from the fires under the boilers are tested as they pass through the smokestack, in order to determine whether or not the firemen perform their duties properly.

Taking all this in conjunction with frequent tests and experimental work on driers, condensers, evaporators and other apparatus, it will be seen that there is plenty to keep a large staff of chemists fully occupied.

In refinery work, what is to be feared more than anything is the house becoming “sour.” Raw sugars and sugar liquors, and particularly the sweet waters, have a tendency to ferment, and fermentation, like fire, if not checked and brought under control before it gains much headway, soon pervades the entire establishment, affecting all the liquors and syrups, thus turning the sucrose or sugar into glucose, which cannot be recrystallized. In a refinery of two million pounds daily capacity, there is double this quantity of sugar in the house in the form of liquors, syrups, sweet water, massecuite and raws. If all of this four million pounds turned “sour,” the money loss, with raw sugar worth four cents a pound, would be about one hundred and sixty thousand dollars. Such a contingency, while remote, clearly demonstrates that chemical control is an absolute necessity.

COST OF REFINING

In concluding that part of the story that deals with refining, some reference may be made to the refining cost and to the price at which refined sugar is sold.

The cost of refining sugar varies in different parts of the United States on account of the difference in the cost of commodities entering into the refining process, such as labor, fuel, cotton, burlap, containers, bone-char, etc. On the Pacific coast nearly all these items are higher than in New York, and consequently the cost of refining is probably greater.

In 1911 nearly all the sugar refiners of the United States appeared before the Hardwick Congressional committee at Washington and the testimony given by them before that body showed that the cost of refining ranged from 60 cents to 65 cents per 100 pounds.

On the day the Congressional committee began its investigation, raw sugar was selling in New York for 3.86 cents per pound, and the testimony regarding the cost of refining was no doubt based on this price for the raw sugar entering the refining operations.

It is therefore fair to assume that under normal conditions, with raw sugar at about 3¾ cents, the average cost of refining in the United States is 62½ cents per 100 pounds. This includes every item from the time the raw sugar is landed on the dock until the refined is loaded on the cars or boats for shipment. It includes the selling and overhead expenses, but not the transportation charges after the sugar leaves the refinery.

During the last six years (1909-14 inclusive) the actual differential in the United States between the purchase price of raw sugar and the selling price of refined has been 82½ cents per 100 pounds. The difference between this figure and the cost of refining represents the refiner’s gross profit; in other words, about 20 cents per 100 pounds, out of which he must pay for all additions and improvements to his plant. The remainder is available for returns on capital invested. This difference varies with the time of year and in different localities, but the average will probably hold good.

A refiner of cane sugar buys his raw product in the open market and must pay for all his operating and administration expenses and obtain his profit from the margin between the buying price of raw and the selling price of refined sugar. The cost of refining is not constant, as it varies with the fluctuating values of fuel, containers, labor, and particularly the cost of raw sugar. If it costs 62½ cents per 100 pounds to refine sugar with raws at 3.86 cents per pound, it will cost about 82½ cents per 100 pounds with raw sugars at 6 cents, assuming that such items as fuel, containers, labor, etc., remain constant. This is due to the greater value of the raw sugar lost in refining, to the heavier insurance premiums and higher interest charges. With high-priced raws, the margin between raws and refined must be proportionately greater to offset the increased cost of refining.

The refiner, like the consumer, would prefer to see sugar selling on a low basis, while the producer always hopes for the opposite.

SHIPPING DEPARTMENT

Here will be found every modern convenience for the rapid loading of cars and steamers. Adequate railway trackage is provided for the handling of shipments moving by rail, and on the waterfront side of the warehouses there is ample berth room for steamers that carry the sugar to cities and towns on the inland waterways and the seacoast, together with points tributary thereto. Facilities are also at hand for local delivery by drays.

Railroad cars are sometimes sent to refineries by water, on car barges, to be loaded with sugar and then towed to what are known as railroad terminals, where the cars are taken from the barges and started on their journey to destination. The capacity of a car varies from twenty-four thousand to one hundred thousand pounds. If an amount of sugar equal to that consumed in the United States in 1915 were loaded into cars containing 1000 sacks of 100 pounds each, it would require 81,087 cars, which would make up a train 768 miles long.

A large part of the product is delivered direct from the packing-room conveyors into the waiting cars and steamers, thus avoiding unnecessary handling. A single shipment frequently includes a number of different styles of package, and great care must be exercised to insure accuracy in count and description.

As dry granulated sugar readily absorbs moisture, every precaution must be taken to make the storage rooms thoroughly damp-proof, so that the sugar may always be in good condition when shipped from the refinery.

Shipments are made only on written orders from the sales department to the head of the shipping department. These orders set forth the name of the buyer, the kinds and quantity of sugar desired, the point to which the sugar is to go, the route by which it is to travel, the date on which it is to be shipped, and the terms of sale. At the proper time the sugar is loaded, shipped, and in due course delivered to the buyer.

MARKETING

The amount of sugar used in the United States in 1915 was 4,257,714 short tons. Of this, 3,389,175 tons were raw cane, the remainder consisting of 861,568 tons of domestic beet and 6,971 tons of foreign refined cane and beet. Of the 3,389,175 tons of raw cane, 150,000 tons were consumed in the raw state, and from the remainder, 3,239,175 tons, about 3,044,825 tons of refined sugar were produced. The per capita consumption was 83.83 pounds, and was made up of:

SHORT TONS PER CENT Refined made from raw cane 3,044,825 74.94 Domestic and foreign beet 862,694 21.23 Foreign refined cane 5,845 .14 Consumed in the raw state 150,000 3.69 --------- ------ 4,063,364 100.00

Among articles of food that contain a large percentage of sugar are jams, jellies, chocolate, canned fruits, condensed milk, confectionery, chewing gum and cordials. It is estimated by Willett & Gray that in 1915 the direct per capita consumption was 31.43 pounds, and that the remaining 52.40 pounds were used in various prepared or manufactured foodstuffs. Over ninety-nine per cent of all the cane sugar consumed in the United States is refined in New York, Boston, Philadelphia, New Orleans and San Francisco. The beet comes chiefly from California, Colorado, Michigan, Utah and Idaho; the maple from the New England states, Ohio and Canada; and the small amount of full duty-paying foreign cane from Java, Peru, Mexico, Central America and Santo Domingo.

During the past eleven years the consumption in the United States has grown at an average rate of 3.57 per cent per annum. In 1911, on account of the abnormally high prices, the increase was practically nil.

The annual per capita consumption of sugar in some of the other countries of the world is as follows:

1914 Servia 4.60 lbs. Greece 8.99 ” Bulgaria 9.94 ” Italy 10.45 ” Portugal 13.60 ” Spain 15.91 ” Roumania 17.12 ” Turkey 20.33 ” Russia 29.26 ” Finland 32.54 ” Austria-Hungary 37.38 ” France 39.01 ” Belgium 42.79 ” Holland 53.44 ” Norway 60.37 ” Sweden 60.48 ” Switzerland 74.87 ” Germany 74.95 ” England 89.69 ” Denmark 93.48 ”

The sale and distribution of large quantities of refined sugar is a serious problem and just as important as the production and the refining of the raw product. Competition is so keen, and the questions involved so complex, that the sale of the product really results in commercial warfare.

To dispose of the output of a large plant successfully requires great intelligence, a broad grasp of business principles, strict honor and integrity, and prompt, decisive action in times of fluctuating markets.

Sales managers of the sugar-refining companies of the United States command high salaries, for the success of the business depends to no small extent upon their ability and judgment. Their knowledge of human nature must be broad and sound and it is tested to the utmost in their selection of assistants and brokers, for representatives always reflect the ideals, principles and methods of the parent authority.

The selling of sugar by the refiner direct to the consumer has not been found practicable, as an organization complete enough to keep in touch with consumers in every city, town and village of the country would be so top-heavy and costly to maintain that the price of the commodity to the consumer would be needlessly increased.

As matters stand, people living in the frozen valleys of Alaska, in the scarcely accessible regions of the Rocky mountains and in the lumber and mining settlements of the West, many miles from railroads, can obtain their supply of sugar with almost the same facility as the residents of New York or San Francisco. A system of distribution that makes this possible leaves little to be desired, and a word or two concerning it will be timely at this point.

Sugar is sold by the refiner to the wholesale grocer through the medium of the refinery's broker. From the wholesaler it goes to the retailer, who in turn delivers it to the consumer.

Brokers are important factors in distribution. In every large city and consuming center, each refinery is represented by its own brokers, who keep in constant touch with all the wholesale grocers and manufacturers of their district.

A thorough knowledge of men and methods, sound business principles, diplomatic talents of no mean order and the capacity to act rapidly, but coolly, in business crises are found combined in the successful broker. He occupies a position between the seller and buyer, and it is just as much his prime duty to see that in all transactions full justice is accorded to both as it is to sell the sugar.

Every refinery having its own broker in each consuming center, it follows that the competition for business among the brokers is very keen. When a broker obtains an order from a jobber or manufacturer, he telegraphs it to his principal. The order is usually confirmed and the goods shipped promptly. For his services the broker receives three cents for every one hundred pounds of sugar sold. This compensates him for the services of his salesmen and himself, his office expenses and cost of telegrams, which is heavy.

Manufacturers of foodstuffs of which sugar is an ingredient, buy their supplies through brokers. They do not resell the sugar as such, but use it only in the manufacture of their own special products.

Wholesale grocery jobbers, of whom there are about twenty-five hundred in the United States, are also very important factors in the distribution of sugar. As a rule, they are located in the large centers of population, and have efficient organizations for the purchase and resale of all kinds of foodstuffs. They deal in as many as three thousand different commodities, and their expense of doing business is apportioned over all of these items, thus reducing to a minimum the expense of handling any one of them. Generally speaking, they have large establishments where stocks of all kinds of goods are carried ready for immediate distribution. The aggregate capital tied up in these stocks throughout the country is enormous, but necessary, as the jobber must at all times be ready to deliver to the retailer whatever is wanted in any of his lines. Wholesale jobbers occupy a unique position in the scheme of things. They are to the commerce of the country what the bankers are to its finances. In other words, they are the bankers of commodities. Their operating staff consists, first, of the buyers, and, second, of the salesmen.

The buyers are men possessing special knowledge concerning the various articles handled by the house. For instance, in the grocery line one will buy nothing but teas and coffees, another canned goods, another sugar, and so on. These men as a rule have devoted years of study to the particular commodity which they are delegated to buy. They are shrewd, keenly alert and always ready to take advantage of market fluctuations in their favor. The margin of profit between the buying and selling price of any commodity is usually so small that the acumen of the buyer is an important factor in the final results.

The salesmen are trained, tactful, tireless and efficient. They travel from town to town and place to place, visiting every nook and corner where human beings congregate, in order to sell the goods carried by the firm. While his calling is a most useful one, the life of a "knight of the grip" is not always pleasant, as he meets with many deprivations and discomforts.

To compensate him for capital invested, for the expense of doing business and for the losses he incurs in bad debts and declining markets, the jobber probably obtains a gross return of fifteen cents on each one hundred pounds of sugar he sells.

The next important link in the chain is the retailer. It is roughly estimated that there are three hundred thousand retail grocers in the United States, many of whom handle and distribute almost as many articles as the jobber. Their lot on the whole is not cast in pleasant places, because of the severe competition they meet in selling their goods.

Competition is a word regarded almost with affection by the buyer, but for the seller of goods it is probably the most unpleasant one in the English language. There is an old axiom which reads: “Competition is the life of trade.” It may be so, but the expression was no doubt coined by a buyer.

Among sellers, competition is in direct proportion to the number engaged in any particular business. It therefore follows that as there are three hundred thousand retailers in the United States, and hundreds in each of all the large cities, the struggle to keep on their feet and continue their various enterprises must be severe. The number of failures occurring every year amply substantiates this assertion. Reckless and unscrupulous men engage in every business, and the competition thus forced on all others in their line is not only unfair, but positively dishonest. Any individual can break a price or introduce new and expensive experiments in selling terms, which must be followed with equally attractive terms by the other sellers, thus resulting in great loss to all. It is no satisfaction that such men finally fail and go out of business, for the losses sustained in the interim can never be recovered.

Another grave difficulty with which the retailer has to contend is the fact that the average individual to whom he delivers his wares is apt to be rather callous when pay-day comes around. It is sad, but true, that those best able to pay are sometimes the most unsatisfactory customers of the retail grocer.

A retailer’s expense of doing business is proportionately much greater than that of the wholesaler, and his losses, due to bad or uncollectible accounts, are much heavier. The cost of delivering goods to the consumer’s door is high, and a fact that should be remembered, but which is frequently overlooked, is that it costs the grocer just as much to deliver a five-pound package of sugar as a wagon-load. Householders are proverbially careless, and telephone calls for late and urgent deliveries are a source of great annoyance and expense.

To create a pleasing impression, the grocer must keep a clean, sanitary store, and the expense incident to attractive window and shelf displays to invite attention is an important item. Department and other stores in his town or neighborhood often advertise “leaders” to attract the buying public, in the hope of selling with these leaders other goods at a profit, or because they are overstocked with a particular commodity. Every retailer must, as a rule, meet this unfair competition or lose his trade.

Sugar more than any other staple article is used as a leader, and, as a result, the retail grocer’s profit on it is very small. What remains to him out of the selling price of one hundred pounds of sugar does not exceed thirty-five cents, and more than likely it has cost him twenty-five cents to sell it. It is the retail grocer’s employé who delivers sugar in the quantity desired to the housewife at her door, and through her hands the pure, glistening crystals reach the family table.

BEET SUGAR

SHORT REVIEW OF THE HISTORY OF BEET SUGAR

The extraction of sugar from beets dates back to 1747, when Andreas Marggraf, professor of physics in the Academy of Science of Berlin, discovered the existence of a sugar in beets similar in its properties to that obtained from cane.

The discovery was little utilized at first, however, and the manufacture of sugar from beets did not attain commercial importance for over half a century, when Franz Karl Achard, a pupil of Marggraf, made discoveries which led to the construction of the first beet-sugar factory in the world, in Silesia, in the year 1799.

The work of Achard soon attracted the attention of Napoleon Bonaparte, who appointed a commission of scientists to go to Silesia to investigate Achard’s factory. Upon their return, two small factories were constructed near Paris. Although these two factories were not altogether a success, the results attained greatly interested Napoleon, and in 1811 he issued a decree appropriating one million francs ($200,000) for the establishment of sugar schools, and compelling the farmers to plant a large acreage to sugar beets the following year. He also prohibited the further importation of sugar from the Indies after January 1, 1813.

As a result of these and other drastic decrees, three hundred and thirty-four factories were erected in France during the years 1812 and 1813, and their production was seven million seven hundred thousand pounds of sugar, or an average of eleven and one-half tons to the factory.

ANOTHER TYPE OF SUGAR BEET]

With the fall of Napoleon Bonaparte, disaster came upon this, one of his greatest achievements, and but one factory survived. The industry was destined to flourish again, however, under the reign of Louis Philippe. In 1836-37 there were five hundred and forty-two factories in France, producing thirty-five thousand tons of sugar, as compared with fourteen hundred and eight tons in Germany, which country had only recently begun the culture of beets.

When Napoleon III became emperor, he so stimulated the industry that in 1853 the French output had doubled. Meanwhile the Germans were making rapid strides, and in 1880 the German output of sugar exceeded that of France. As a result of legislative encouragement, Germany today is the largest beet-sugar producer in the world.

The first successful beet-sugar factory in the United States was constructed by E. H. Dyer, at Alvarado, California, in 1879. The next successful factory was erected at Watsonville, California, in 1888, by Claus Spreckels. The Oxnard brothers followed with the construction in 1890 of a factory at Grand Island, Nebraska, one at Norfolk, Nebraska, and a third at Chino, California, the last built in 1891.

From this it will be seen that the commercial production of beet sugar in the United States really dates back to about 1890, since only three factories of small capacity had been established prior to that date. The development of the industry since the year 1892 has been rapid, and the general results of the beet industry in the United States in 1915 showed the following:

Factories in operation 67 Acres of beets harvested 611,301 Average yield of beets per acre 10.10 short tons Beets worked 6,150,293 ” Sugar manufactured 874,220 ”

The season of 1916 promises a notable increase in tonnage.

THE SUGAR BEET

The botanical name of the sugar beet is _Beta vulgaris_. It grows exclusively in the temperate zone, and with satisfactory soil and climatic conditions a yield of thirty tons per acre has resulted. The average yield in the United States, however, is slightly over ten tons per acre. There are many varieties of beets, some of which do better in one locality than another, so that great care must be used in the selection of the seed.

The beet, unlike sugar cane, grows below the ground, is white in color and shaped like the ordinary carrot, but larger. The beets vary greatly in size, depending upon variety, soil and climatic conditions, the average weight ranging between one and two pounds.

The foliage has a rich, brilliant green color and grows to a height of about fourteen inches. The leaves are numerous and broad and grow in a tuft from the center or crown of the beet, which is usually level with or just above the ground surface.

The average composition of a sugar beet is about as follows:

Sugar 17.3 per cent Marc or pulp 4.4 ” Ash and organic non-sugar .7 ” Water 77.6 ”

The value of the beet to a factory depends on the amount and purity of the sugar content. Factories as a rule decline to purchase beets containing less than twelve per cent of sucrose, as it is unprofitable to handle them. In order to induce the farmer to devote particular care and attention to the culture of his fields and thus increase the sugar content, the factories pay a premium for beets containing over fifteen per cent of sugar. The premium is usually twenty-five cents per ton of beets for each additional one per cent of sugar. Encouraged by this bonus, the California grower has improved the quality of his beets, until today they contain on an average about eighteen per cent of sugar of a purity from eighty to eighty-four.

PLANTING BEET SEED]

SELECTION OF THE SOIL

The sugar beet, like sugar cane, needs a peculiar soil and climate for its successful cultivation. The most important requirement is that the soil shall contain a large supply of plant food, be rich in humus and have the property of retaining a great deal of moisture. A certain amount of alkali is not necessarily detrimental, as sugar beets are not especially susceptible to injury from this salt. The ground should be fairly level and well drained, especially where irrigation is practiced.

While the physical character is of secondary importance, as generous crops are grown in sandy soil as well as in heavy loams, still the ideal soil is a sandy loam, _i. e._, a mixture of organic matter, clay and sand. A subsoil of gravel, or the presence of hard-pan, is not desirable, as cultivation to a depth of from twelve to fifteen inches is necessary to produce the best results.

Climatic conditions, temperature, sunshine, rainfall and winds have an important bearing upon the success of beet culture. A temperature ranging from 60 degrees to 70 degrees Fahrenheit during the growing months is most favorable. Sixteen inches of rainfall are necessary to raise an average crop of beets without irrigation. High winds are very harmful, as they generally crust the land and prevent the young beets from coming through the ground. The best results are obtained along the coast of southern California, where warm, sunny days succeeded by cool, foggy nights seem to meet every requirement. Sunshine of long duration but not of great intensity is the most important factor in the successful cultivation of sugar beets. The nearer the equator is approached, the poorer the beets become in sucrose because of the shorter days and the greater heat of the sun. Beets have never been raised with success in the hot interior valleys, as the hot days followed by warm, dry nights sap the vitality of the plant. In the elevated Rocky mountain region of Colorado and Utah, where the temperature is high during the daytime but where the nights are cool, the quality of the beet is excellent.

In Michigan the long summer days and the influence of the great lakes result in satisfactory climatic conditions for sugar-beet culture, and the crops raised in that state are large.

In order to cultivate beets successfully the land must be properly prepared. Deep ploughing is the first principle of beet culture. It allows the roots to penetrate the subsoil without much obstruction, thereby preventing the beet from growing out of the ground, besides enabling it to extract considerable nourishment and moisture from the lower soil. If the latter is too hard, the roots will not penetrate it readily and, as a result, the plant will be pushed up and out of the earth during the process of growth. A hard subsoil is impervious to water and prevents proper drainage. It should not be too loose, however, as this allows the water to pass through more freely than is desirable.

The character of the surface soil is equally important. Careful preparation by harrowing should be done to afford a finely pulverized and clean bed for the seed.

To sum up, the soil should be deep, fairly fine and easily penetrable by the roots. It should also be capable of retaining moisture and at the same time admit of a free circulation of air and good drainage.

PLANTING

The preliminary preparation of the ground finished, the seed should be put in as soon as the soil is firm enough to allow it to germinate readily and the young plants to grow normally. The time of planting varies according to climatic conditions. In California planting begins as a rule in December and ends in March, while in Utah, Colorado and Michigan it ranges from March until May.

[Illustration: _By permission of Truman G. Palmer, Esq._

THINNING]

[Illustration: _By permission of Truman G. Palmer, Esq._

CULTIVATING]

About twenty pounds of seed to the acre are required to produce a satisfactory stand. The seed is planted in rows, about eighteen inches apart, and is drilled in solidly to a depth of from three-quarters to one and a half inches. The latter is the maximum, as any greater depth than this weakens the plant and should, therefore, be avoided. The soil around the seed is well packed by the planter in order to draw the moisture necessary for germination.

The production of beet seed presents many problems; the chief one is to obtain the particular kind of seed that will bring forth a hardy beet containing a large percentage of sugar of a high purity. The beets from which the seed is produced are selected with the greatest care, and for nearly a century the Luther Burbanks of Europe have devoted their time and skill to improving the quality. Until recently, practically all of the beet seed used in the United States was imported from Europe. Since the outbreak of the great war in 1914, however, the difficulties attendant upon securing a supply have caused the beet growers to turn their attention to raising seed in this country. Their efforts have been rewarded with a fair measure of success, and while the cost is greater than that of European seed, the germinating properties have proven to be excellent. The best results have been obtained in Idaho. Owing to the fact that the culture of the beets and the picking and sorting of the seed are done chiefly by hand, labor enters largely into the cost of production, and consequently, under normal conditions, the growers in the densely populated countries of Europe have a great advantage over those in the United States, where the main difficulty is securing labor for the field work.

Like sugar cane, beets are subject to plant diseases of various kinds, as well as to injury by insect pests, and great care has to be exercised to ward off these dangers.

Probably no other crop exhausts the soil so rapidly as beets, and, if they are planted for many years in succession, they deteriorate year by year. On the other hand, if crops are rotated so that beets are grown in the same ground every third year, peas, beans or grain being raised the other two years, it is a remarkable fact that all of these crops will improve each year. This is due to the intensive cultivation of the beets and to the humus left in the ground in the form of rootlets. Experience has taught the farmer that no other crop is so beneficial to the soil as beets grown in the right rotation and with proper care.

THINNING

As soon as the beets are up and the rows clearly defined, thinning becomes necessary. This is one of the most important features of beet culture and is a tedious and expensive operation. It consists of cutting out the plants so that individual roots remain, spaced about eight inches apart. The work is done by hand, a hoe being used to block out the spaces, and the roots surrounding the one which it is desired to retain are pulled up. Due partly to faulty germination, but principally to defective thinning of the beets, in which operation a great many of the small, tender beet plants are injured or killed, very much less than the theoretical number of mature beets are secured per acre. With rows eighteen inches apart and a plant every eight inches in the row, 43,000 beets per acre should be obtained, which, at an average weight of one and one-half pounds per beet, would mean 32.25 tons. Owing, however, to the facts just mentioned and to other causes, the actual yield is always much less. The average in California for a number of years past has been only 10.68 tons per acre.

[Illustration: _By permission of Truman G. Palmer, Esq._

FIELD OF RIPE BEETS]

[Illustration: _By permission of Truman G. Palmer, Esq._

TOPPING BEETS]

CULTIVATION

The purpose of cultivation is two-fold; first, to retain the moisture in the soil, and, second, to destroy the weeds and grass, as in the early stages of the growth of the beets weeds might spoil the stand by choking the plants.

Cultivation should be continued until the plants have attained such a size that the leaves cover the ground. It increases the fertility of the soil by opening the land to the atmosphere, thus facilitating the penetration of oxygen and absorption of air moisture and the resulting decomposition and assimilation of nutritious elements.

HARVESTING AND TOPPING

The time when harvesting takes place depends on the many factors that influence the growth and maturing of the beet. In the colder countries the harvesting lasts from September until the ground becomes frozen, while in warmer climates like that of California, where the seed is planted early, harvesting begins about July first and lasts for a period of from seventy-five to ninety days.

The beets are first loosened by means of a specially shaped plough, called the “puller,” which lifts them from the ground. They are then picked up by hand and the crown of each beet, together with the leaves, is cut off with a large knife. The leaves contain no sugar, and are, therefore, not taken into the factory, but are utilized for stock feeding, being quite valuable for this purpose. The sugar contained in the crown is accompanied by so many organic salts that it does not pay to extract it.

The topped beets are then loaded into wagons or railroad cars and transported to the factory, at which point they are carefully weighed. In this country most of the beets are raised by farmers and sold under contract to the factories, at so much per ton, so that the determination of the exact weight and sucrose content is important. For the season of 1915 the average price paid to the farmers for beets was $5.67 per ton.

On arrival at the factory a certain number of beets are taken from every wagon- or car-load, and these represent a fair average of all the beets of that particular delivery. They are sent to the laboratory and their exact weight ascertained, after which they are trimmed of all adhering roots, leaves and parts of the crown, if not properly topped in the field. Any remaining soil is carefully brushed off and the beets thoroughly cleaned. They are then reweighed and the difference between this and the first weight is the tare. This difference represents a certain percentage of the total of the sample beets weighed, and that small percentage is deducted from the gross weight of the total load. In this way the exact net weight of beets delivered by the farmer is determined and he is paid according to this net weight.

The sugar content of the beet and the purity of the juice must now be ascertained, for the price paid the farmer varies according to the amount of sugar the beet contains. As in the case of weighing, sampling and polarizing raw cane sugar, representatives of both parties—the farmer and the factory—are present when all weights are taken and tests made. There are several different methods for determining the percentage of sugar in the beet and the purity of the juice, but the following gives a fair idea of the general practice.

The sample beets having been cleaned, are cut into quarters, one-quarter of each beet being taken for the general sample. This general sample is placed in a grinding or shredding machine, the beets are disintegrated to a fine pulp and thoroughly mixed. A specific amount of this fine pulp is then accurately weighed and placed in a copper pan or dish called a capsule. A small quantity of dilute lead solution is introduced to assist in clarifying, and sufficient water added to bring the volume up to 200 cubic centimeters. It is then heated for about twenty minutes and vigorously agitated, so that the sugar-bearing juice of the beet will mix evenly with the water that was added. The mixture, after being allowed to stand for several minutes, is filtered through paper and a certain amount placed in the observation tube of a polariscope. The instrument will show the amount of sugar in the solution, and by multiplying the reading by two the per cent of sugar in the beets will be found. If in preparing the sample only sufficient water had been added to bring it to a volume of 100 cubic centimeters, the polariscope would give a direct reading of the percentage of sugar in the beets. Practice has demonstrated, however, that the method described is the more accurate.

[Illustration: _By permission of Truman G. Palmer, Esq._

HAULING BEETS]

[Illustration: _By permission of Truman G. Palmer, Esq._

DELIVERING BEETS TO THE FACTORY BY WAGON]

To ascertain the purity of the juice, the procedure is as follows: A part of the shredded sample is taken and the juice is squeezed out of it. The amount of sugar in this juice is determined by aid of the polariscope, and a Brix spindle shows the amount of solids it contains. By dividing the polarization by the Brix and multiplying by 100 the purity is obtained, which means the percentage of pure sugar in the total amount of solids contained in the solution.

The purity of the juice has an important bearing on the subsequent manufacture of the sugar. It is difficult and costly to extract sugar from low-purity juices, and the loss of sugar in the process is very high. The reverse is naturally true if the juices have a high purity. The purity of the juice in the beet is materially affected during the growing period by climatic conditions, rainfall, irrigation,

fertilization, state of soil and cultivation. Great care and attention must be given the beet to insure high purity and heavy content of sugar.

From the above it will be seen how the net weight and the percentage of sugar in any particular wagon- or car-load of beets are ascertained, as well as the purity of all the beets that enter a factory. The efficiency of the work in a factory is based on the figures thus obtained.

MANUFACTURE OF BEET SUGAR

The process of making sugar from the beet is highly technical in its details and cannot be fully discussed within the scope of this work. A brief description, however, will give an idea of the general methods followed.

The process of manufacture may be classified under seven headings:

1. Transportation and cleaning of beets. 2. Extraction of juice, slicing and diffusion. 3. Purification, carbonation, filtration, concentration and sulfitation. 4. Formation of grain. 5. Partial drying, purging crystals from syrup in centrifugals. 6. Final drying. 7. Packing.

TRANSPORTATION AND CLEANING

The beets, after delivery to the factory, are stored in V-shaped bins, in the bottom of which is a flume covered by removable boards. By removing the boards, one at a time, the beets are fed into the flume, where a swift current of water floats them into the factory. From this flume the beets are lifted by means of a large wheel, a helical screw or any other suitable device, and discharged into a washer.

The common form of washer consists of a horizontal, semi-cylindrical tank provided with rotating, kicking or stirring arms for keeping the beets in motion. In this tank the beet is completely cleaned and separated from adhering earth, weeds and pebbles.

DELIVERING BEETS TO THE FACTORY BY TRAIN]

[Illustration: _By permission of Truman G. Palmer, Esq._

GENERAL INTERIOR VIEW OF BEET-SUGAR FACTORY—SHOWING FILTER PRESSES IN FOREGROUND; PANS AND EVAPORATORS IN REAR]

The beets are delivered from the washer into an elevator, which takes them to a point near the top of the factory and discharges them into automatic weighing and recording scales. From the scales the beets fall by gravity into the slicing machines.

EXTRACTION OF JUICE, SLICING AND DIFFUSION

The slices are made in various shapes and forms. The slicing machines consist of revolving, corrugated knives which cut the beets into long, thin slices or “cossettes.” The object is to produce slices which expose the greatest amount of surface, and yet sufficiently firm to lie not too closely together when placed in the diffusion battery, thereby preventing the circulation of the diffusion liquors. The cossettes are conveyed on an endless belt, or through a hopper, to the cells of the diffusion battery.

As the term implies, the juice in the beet is extracted by diffusion, and not by crushing, as in the case of cane. When two liquids, separated by a membrane, are brought in direct contact with each other and allowed to stand for a time, they mix uniformly without the assistance of mechanical or other force.

Beets are made up of a great number of plant cells, the walls of which are porous membranes. These cells are placed in contact with water or juice of lesser sugar content than the juice in the plant cell, in consequence of which the juice is gradually diffused from the beet and carried away in the circulating water which is added. When this water, or rather juice, has reached a certain stage of concentration, it is drawn out of the cells and sent to the next stage in the process of manufacture.

A diffusion battery, or the apparatus in which the process of diffusion is carried on, consists of a number of tanks or cells, usually from ten to fourteen, cylindrical in shape and terminating in truncated cones provided with covers. There are two ways of arranging the cells of a diffusion battery; in the one case the cells are placed in a straight line; in the other they are grouped in a circle. These

cells are filled with cossettes in rotation, and water is introduced into the one in which the cossettes were first placed.

Thus the water enters the tank in which the cossettes are nearly exhausted of their sugar, and it flows successively through the other cells that contain cossettes of greater sugar content until the last cell, or the one containing fresh cossettes, is reached. The juice passing through this cell is alternately sent to the measuring tank or to the next cell, which has just been filled with fresh cossettes. The process is continuous, one cell being emptied of exhausted cossettes while another is being filled with fresh ones, and the juice flowing either to the measuring tank or to the freshly filled cell.

The exhausted cossettes, now called pulp, are dropped from the bottom of the diffusion tanks into a large bin, from which they are conveyed or pumped to pulp separators and presses for the separation of the surplus water. This pressed pulp is usually stored in large bins or silos, where it is allowed to ferment before being fed to cattle.

Recently the practice of drying the pulp has been carried on to a large extent. In this process the moisture in the pulp is reduced to ten per cent, the same proportion as in cured hay. Dried to this point, it is packed in bags and may be stored for an indefinite period without deteriorating. After being treated thus it forms an excellent stock food, particularly if waste molasses is sprayed on it before drying.

PURIFICATION OF JUICE, CARBONATION AND FILTRATION

The diffusion juice obtained as above described is quite dark in color, and after passing through the measuring tanks it is conveyed to carbonation tanks where it is treated with from three to four per cent of caustic lime in the form of a thick milk.

[Illustration: _By permission of Truman G. Palmer, Esq._

DIFFUSION BATTERY—SHOWING DIFFUSION CELLS IN CIRCULAR ARRANGEMENT]

[Illustration: _By permission of Truman G. Palmer, Esq._

DIFFUSION BATTERY—SHOWING DIFFUSION CELLS IN STRAIGHT LINES]

After being thoroughly agitated, the mixture is treated with carbonic acid gas obtained from the lime-kilns, as the result of the decomposition of limestone and the combustion of the fuel used for burning it.

By this process some of the impurities in the juice are removed and the color reduced to a brilliant amber. As is the case in the cane mills and refineries, it is essential to keep the juice hot throughout the process. The carbonation is continued until the juice is only slightly alkaline, when it is passed through filter presses for the removal of the precipitated lime carbonate and other solid matter. The solid matter in suspension is retained in the frame of the press, and, as soon as the frame is full, the cake is washed by passing water through it. When the sugar content of the cake has been sufficiently reduced, the press is opened and the cake discharged and sent to the fields to be used as a fertilizer.

As a rule, the filtration is repeated for the elimination of any solids that may have passed through the first filtration. This double filtration is usually practiced in all the filtrations in the course of the juice through the factory.

The juice after being filtered a second time is again treated with carbonic acid gas for the further reduction of the caustic lime and then undergoes a third filtration, following which it is sent to the evaporators for concentration.

CONCENTRATION OF JUICE

When the juice reaches the evaporators it contains about eighty-two per cent of water, which, by concentration, must be reduced to about forty per cent. As already explained, the removal of water is generally accomplished in multiple-effects. The apparatus consists of a number of boiling bodies connected in such a manner as to secure a progressive decrease in atmospheric pressure.

The thin juice enters the first body where evaporation takes place under a slight pressure. The steam for this evaporation is usually the waste or exhaust from the engines and pumps. The vapors generated by the evaporation of water from the juice in the first body enter the heating tubes of the second body and are used in further concentrating the somewhat concentrated juice from the first body. The evaporation in this second body is conducted at a higher vacuum and corresponding lower temperature than in the first body. This proceeding is continued until five or even six bodies are used in the series. The last body is usually under a vacuum of about twenty-six inches of mercury.

It is obvious that by this arrangement the concentration of the thin juice is effected with the maximum of economy, direct steam being admitted into the first body only and the rest of the operation accomplished by the steam generated in the boiling of the juice.

SULFITATION

The thickened liquor leaving the last body of the evaporators is sent to the sulphur station and treated with sulphur fumes, in order to further precipitate the soluble impurities and reduce the color of the liquor. It is then heated to boiling point in closed tanks and passed through a double set of cloth filters. This is the final process in the purification of the beet juice, and it is then ready for graining.

In a cane-sugar refinery no sulfitation of the liquor takes place, and in a beet factory there is no char filtration for removal of color and impurities in the liquor. These two points constitute the main difference in the methods of making white sugar from the cane and the beet in the United States. In Europe, however, many factories make a raw beet sugar, which is subsequently refined with the aid of bone-char.

WEIGHING, FILLING AND SEWING BAGS IN A BEET FACTORY]

[Illustration: _By permission of Truman G. Palmer, Esq._

CATTLE FEEDING ON BEET PULP]

FORMATION OF GRAIN

The formation of the crystallized grain and its progress through the vacuum pans, centrifugals, driers, granulators and screens, and into the bags in the packing room, is identical with the process in a cane refinery, which has already been described.

STEFFEN PROCESS

In some of the beet factories the sugar left in the final molasses is extracted by what is known as the Steffen process. The final low-purity molasses is diluted with water and cooled to a very low temperature, after which finely powdered lime is constantly added to the solution at a uniform and slow rate. The sugar combines with the lime and a saccharate of lime is formed which is insoluble in the liquid. The suspended matter or saccharate is then separated and washed in filter presses.

The cake from these filter presses, which is the saccharate of lime, is mixed with sweet water to a consistency of cream and takes the place of milk of lime in the carbonation process. When the Steffen process is employed, about ninety per cent of the sugar originally in the beet is extracted. The loss of sugar that does take place is accounted for in the exhausted cossettes or pulp, in the pulp water which surrounds them when they are dumped from the diffusion cells, in the cake and wash waters from the carbonation presses and in the waste and wash waters from the Steffen process. As the water used in washing the saccharate press cake is rich in fertilizing qualities, it is used for irrigating the lands adjoining the factory.

The 6,511,274 tons of beets harvested in the United States during the season of 1915 contained an average of 16.49 per cent of sucrose, of which 14.21 per cent found its way into the sacks as white sugar. The difference, 2.28 per cent, represented the loss in working up the beets. As only a few factories, however, were using the Steffen process, a considerable amount of sugar was left in the waste molasses. For the same period, the beets produced in California contained 17.82 per cent of sugar, of which 15.64 per cent found its way into the sacks, showing a loss of only 2.18 per cent. This may be accounted for by the fact that probably more of the California factories were equipped with the Steffen process than the average for the United States, and that the purity of the juices of California beets was higher than the average for the United States.

A factory equipped with the Steffen process and running on beets containing 17.82 per cent sugar, with a purity of 82, should lose not over 1.9 per cent of the sugar in the beet. The same factory without the Steffen process would probably lose 5.04 per cent of the sugar.

It is interesting to know that, according to the testimony given before the Hardwick committee, the average cost of producing and selling one hundred pounds of white beet sugar in the United States today is about three dollars and fifty cents. The selling price, which is from ten to twenty cents per one hundred pounds less than the selling price of refined cane sugar, fluctuates with the value

of raw cane sugar. For instance, if raw cane sugar is selling in New York at four dollars per one hundred pounds, the selling price of refined cane will probably be four dollars and eighty cents. Beet sugar, therefore, would be four dollars and seventy cents or four dollars and sixty cents. On the other hand, if raw cane were selling for three dollars per one hundred pounds, refined would probably be three dollars and eighty cents and beet sugar three dollars and seventy or three dollars and sixty cents. In the one case the beet factory makes a large profit; in the other a very small profit.

As the value of raw sugar is determined absolutely by the law of supply and demand in the world's markets, it is clear that the fortune or misfortune of the beet-sugar producer is beyond his control.

PART II

History of the Industry

EARLY HISTORY

India, the land that Kipling has called "the grim stepmother of mankind," is, according to the best authorities, the original habitat of the sugar cane; and there is but little doubt that the properties of the plant were known to the Hindustani many centuries before the Christian era. Nothing concerning it is found in the Old Testament, the Talmud or in the oldest Hindu literature; and even in Buddha's time (500 B. C.) it was little known.

The legend runs that sugar cane was created by the famous hermit Vishva Mitra to serve as heavenly food in the temporary paradise arranged by him for the sake of Raja Trishanku. It was the desire of this prince to be translated to heaven during his lifetime, but Indra, the ruler of the celestial realms, had refused to admit him. In order to gratify Trishanku's wish, Vishva Mitra prepared a temporary paradise for him. When a reconciliation between Indra and Trishanku was brought about, the paradise was demolished and all its luxuries destroyed save a few, among which was sugar cane. This subsequently spread over the land of mortals as a lasting token of Vishva Mitra's miraculous deeds.

Among the Chinese the first historical mention occurs in writings of the eighth century B. C., where the fact is recorded that their knowledge of sugar cane was derived from India. That it was considered of great value by the Chinese is shown by manuscripts of 200 B. C., wherein it is stated that the kingdom of Funan paid its tribute to China in sugar cane. From this it may be inferred that the secret of extracting crystals from the sugar-cane juice had not been discovered.

More than three centuries before Christ, the triumphant progress of Alexander the Great was halted upon the banks of the river Indus by the refusal of his troops to venture farther eastward. On their return journey, the Macedonian soldiers carried the "honey-bearing reed" to Europe.

A number of classical writers of the first century allude to the sweet sap of the Indian reed and to the granulated, salt-like product imported from India under the name of _saccharum_, or σ■κχαρι, from the Sanskrit _çarkar■_, gravel, sugar. The names of sugar in modern European languages are derived through the Arabic from the Persian _shakar_.

The people dwelling in the valleys of the Ganges possessed a knowledge of boiling sugar juice, and this spread from there to China in the first half of the seventh century. Sugar refining, however, could not then have been known, for Marco Polo[5] states that the Chinese learned this from Egyptian travelers only during the Mongol period, some five hundred years later. Von Lippmann says that solid sugar began to be known in India somewhere between 300 and 600 A. D., probably nearer the latter date.[6] In the Middle Ages, the best sugar came from Egypt[7]; and in India today, coarse sugar is still called "Chinese" and fine sugar "Cairene" or "Egyptian."

The Nestorians, a Christian religious sect in Gondis■p■r, India, planted sugar cane in Persia about 500 A.D. When Heraclius,[8] the Byzantine emperor, pillaged the palace of Dastargerd, Persia, in 627 A. D., solid sugar was taken among the other loot.[9] This

is the first authentic evidence of crystallization. At the time of the Arabian conquest in the year 639, sugar was “prepared with art” in Gondis■p■r; and its manufacture on a large scale was carried on at Shuster, S■s[10] and Askar-Makram[11] through the Middle Ages. Thaálibí, a writer of the eleventh century, says that Askar-Makram had no equal for the quality and quantity of its sugar, “notwithstanding the great production in Ir■k, Jarj■n and India.” It used to pay fifty thousand pounds of sugar to the Sultan in annual tribute.[12] Persian physicians of the time attributed extraordinary healing powers to sugar, and used it freely in the practice of their art.

Mohammed’s[13] religious wars carried the knowledge of sugar throughout the cities of the then civilized world. The Arabs first learned of it when they overran Persia. They took to it eagerly, and under their rule a great number of plantations were started. Artificial irrigation was employed in the growing of the cane, and the juice was expressed by means of millstones. At this period, however, sugar was looked upon as a rare and costly luxury, to be indulged in only by the wealthy, and sparingly even by them.

Arabian doctors who were well advanced in learning gave sugar an important place in their pharmacopœia. The Moslem armies took it westward with them; and when Amru[14] conquered Egypt (640-646 A. D.), it was introduced in that country. Careful methods of cultivation, coupled with the Egyptians’ intimate knowledge of chemistry, brought about excellent results. This cultured people had a simple process for purifying and recrystallizing saltpeter, and they soon found that sugar could be similarly treated.

The first crystals were remelted; and to the liquor so obtained albumen and lime were added. The precipitated impurities were removed by filtration, and the clear syrup boiled down to a grain once more. The syrup, or mother-liquor in which these grains remained after boiling, was eliminated by washing, leaving the white sugar crystals, which in point of quality far surpassed any product then known.

From this time forward, the traffic in sugar began to gain in importance and volume. Nasiri Khosrau, in his account of his travels in Egypt in the eleventh century, narrates that at the celebration of the great Ramazán feast, the Sultan’s table was decorated with sweetmeats consisting entirely of marzipan[15] modeled into shapes of orange trees and statues.

The continuation of the movement of the Arabs toward the west carried the cultivation of sugar over the entire northern coast of Africa and thence into Spain in the year of the conquest of Granada by the Moors (715 A. D.). It made its way to Sicily in 703; it was found growing at Assuan, on the Nile, in 766, and the Crusaders discovered important sugar plantations in Tripoli, Mesopotamia, Syria, Palestine, Antioch and other places in the Levant. Commercial relations between these points and the principal Italian cities were established during the Crusades, and a considerable trade in sugar followed.

Sugar-cane cultivation seems to have appealed to the Crusaders as a profitable venture—so much so that they actively interested themselves in it, making Tyre an important center of the traffic. King Baldwin and various orders of knighthood established large cane plantations in Antioch, Syria and Cyprus and did much to advance sugar production in those countries.

The Crusaders who had acquired a taste for sugar when in the Far east naturally wished to continue its use after their return home; thus, a trade sprung up between northern Europe and Venice, Genoa and Pisa.

After the fall of Acre in 1291, the Crusaders lost their foothold in Asia Minor; but Tyre, Beirut, Antioch and the valley of the Jordan continued to produce good crops of sugar, while Damascus and Tripoli became refining centers. Cyprus, still under Venetian rule, extended its trade in sugar, and sent considerable quantities annually to the mother city. All this time the production in Egypt went steadily forward.

This prosperity was rudely interrupted by the aggression of the Turks. Constantinople was captured in 1453 and Trebizond fell in 1461. The other commercial towns of Asia Minor and all of Genoa’s Black Sea colonies followed in quick succession. Trade between Europe and Asia Minor decreased as a matter of course and the manufacture of sugar languished under Turkish rule.

In 1517 Cairo was taken by the Turks, and Egypt became a province of the Ottoman empire, with disastrous results to the sugar industry there. In 1522 Rhodes, and in 1571 Cyprus, passed under the sway of the Turk; but by that time sugar cultivation in these islands had fallen off greatly, while in Sicily it had completely died out.

Other causes militated to bring about the decline of the sugar trade in these countries. The Portuguese took sugar cane to Madeira in 1419. In 1432 they captured and colonized the Azores; and between 1456 and 1462 they acquired the Cape Verde islands. São Thomé, Principe and Annobon were annexed in 1496; and in that same year the Spaniards colonized the Canaries. Sugar cane grew luxuriantly in the mild, moist climate of these islands, and the cost of production by slave labor was so low that neither Cyprus

nor Sicily could compete; consequently, the once large and prosperous sugar trade of the Mediterranean became a thing of the past.

During the Middle Ages, Venice was the chief sugar-distributing center in Europe. One of the earliest references to sugar in Great Britain is that concerning one hundred thousand pounds shipped to London in 1319 by Tomasso Loredano, a Venetian merchant. Wool, which at that time constituted the most important staple of English products, was exchanged for sugar. In the same year, an entry appears in the accounts of the Chamberlain of Scotland, showing a payment for sugar at the rate of one shilling and nine pence halfpenny per pound. It is said that at the end of the fifteenth century a citizen of Venice received a reward of 100,000 crowns ($111,940) for having invented the process of making loaf sugar. Vasco da Gama's exploit in finding the way to Calicut by sea in 1498 deprived Venice of her position as a dominant commercial center; and new routes for the world's trade were opened up. The discovery of America exercised a still greater influence upon the production and distribution of sugar.

Christopher Columbus' first attempt to establish sugar growing in Santo Domingo in 1493[16] was not a success; but when negro slaves were brought to the West Indies by the Portuguese and the Spaniards, the industry took a new lease of life, and with slave labor, ideal climate and fertile soil, it increased abundantly. As illustrative of the extensive development in Santo Domingo, it is interesting to note that Charles V of Spain obtained from import taxes on Santo Domingan sugar the vast sums of money expended in the building of the royal palaces at Madrid and Toledo.[17]

Brazil was discovered by Pinzon in 1499[18] and sugar cane was taken there from Madeira. About thirty-three years later plantations had been laid out and the first sugar factory built. The year 1590 saw one hundred and two mills in operation in the provinces of Bahia and Pernambuco; and in 1600 the quantity of sugar exported from Brazil was 15,000 tons. At that time Brazil belonged to Spain, which had annexed Portugal and her colonies in 1580. It was conquered by the Dutch in 1629, and a great many sugar plantations and factories were destroyed; but these were subsequently restored by the new rulers. The Dutch, in turn, were expelled in 1655; and in 1661 Brazil was acknowledged to be a Portuguese possession. The sugar trade suffered, however, on account of the banishment of twenty thousand Dutch in 1655, and also through the discovery of gold in 1725, which drew the laborers from the sugar fields and mills; and the production fell off to a large extent.

The island of St. Christopher (now St. Kitts) was occupied in 1625 by both the English and the French. Ten years later the French took Guadeloupe and Martinique; Barbados became a British possession in 1627, and Jamaica was annexed in 1656. Sugar cane was planted in all these colonies, but through lack of knowledge and experience the product obtained was of indifferent quality. A decided improvement was brought about when the Dutch, who were expelled from Brazil, came to the islands in 1655.

Santo Domingo was taken over permanently by the French in 1697 after it had previously been occupied and abandoned by them. From this date the industry throve there and for upward of one hundred years Santo Domingo ranked among the foremost of the sugar-producing islands of the West Indies. Tyranny and cruel treatment caused the slaves to revolt in 1791; the whites who failed to escape were exterminated and the sugar plantations and mills were destroyed.

Santo Domingo has never recovered the prestige in the sugar world that she lost in this way. Her misfortune gave a great opportunity to Jamaica, whose production increased so rapidly that at the close of the eighteenth century she outstripped all the other West Indian islands. The falling off in Santo Domingo stimulated the industry in Cuba as well. As a dependency of Spain, Cuba was hampered by a number of restrictions; these were repealed in 1772, after which the sugar tonnage grew apace.

St. Eustatius and Curaçao belonging to the Dutch, and St. Croix, St. John and St. Thomas to Denmark, also came in for their share of the benefit growing out of the impetus given to the sugar trade at this time. It must be borne in mind, however, that they were conveniently situated for sugar smuggling, of which there was not a little during the American Revolutionary war.

In the countries of South America, Brazil excepted, the sugar trade had become well established. French planters settled in Cayenne in 1634 and in Surinam six years later, but production was handicapped by the difficulty attendant upon securing labor, and this condition continued to exist even after the taking of Surinam, Essequibo, Demerara and Berbice by the Dutch. Finally the trouble was overcome by bringing in slaves, and with the end of the French war the sugar industry began to prosper, especially in

Surinam. During subsequent hostilities these colonies were taken by France, afterwards by England, and later still they reverted to the Dutch. Today they are all British with the exception of Surinam and Cayenne.

Sugar cane was not known in Peru at the time of Pizarro's first expedition to that country (1527), but it was brought there shortly afterward. In Chile and the Argentine its introduction was comparatively recent. The Jesuits took it from Santo Domingo to Louisiana in 1751, and in Mexico it dates back to the time of Cortés.

The rapidity of the increase in the production of the Americas threatened the plantations of Madeira, the Cape Verde islands and the Canaries with extinction and drove them from the world's markets.

Sugar cane was planted by the French in the Ile de France (Mauritius) in 1747, and some years later in Bourbon (Réunion) and sugar made in these islands was sent to Europe about the end of the eighteenth century.

In Java sugar cane has been grown since a very remote period. It was probably brought there by Chinese traders and there is evidence that the Chinese introduced it in the Philippine islands, as the names of the implements and methods used there distinctly point to Chinese origin.

The cultivation of sugar cane in Australia was begun only fifty years ago; it was started in the Fiji islands in 1880, while Captain Cook found cane growing luxuriantly in the Hawaiian islands when he discovered them in 1778.

The wars between Great Britain and France during the latter part of the eighteenth century and the beginning of the nineteenth had a very bad effect on the cane-sugar trade and its development. There was constant fighting in West Indian waters and many merchant vessels were taken as prizes; a disastrous state of affairs for planters and merchants alike. After the battle of Trafalgar had definitely established British supremacy on the seas, Napoleon put into effect his "Continental System," which dealt a severe blow to cane sugar. This opens up a new and interesting chapter in the history of the industry.

BEET SUGAR IN EUROPE

The destruction of the French fleet by Nelson in 1805 thwarted Napoleon's long-cherished plans for the invasion of England. Nothing daunted, however, he immediately bent his efforts toward isolating Great Britain and cutting commercial communications between her and the continent of Europe. The Berlin edict of 1806 prohibited all trade relations with England and made her goods and those of her colonies subject to seizure. England's reply was to forbid ships of all nationalities to enter French ports under penalty of confiscation. Napoleon followed this with the Milan decree which made any vessel that had submitted to English examination or paid dues in English ports subject to confiscation. The one government vied with the other in preying on commerce. The interference with the importation of sugar due to this condition drove prices upward to a point where only a few could afford its use.

Napoleon was fully cognizant of what a privation this was to his people, but he felt confident that means would be found to bring sugar from the Far east to western Europe by way of Constantinople and Vienna; besides, he had strong hopes that a substitute for cane sugar could be produced in Europe itself. He encouraged experimental and research work, keeping thoroughly informed as to progress made, and on March 25, 1811, he issued the famous decree that set in motion the beet industry of the world.

[Illustration: DAN SWEENEY

Olivier de Serres]

[Illustration: DAN SWEENEY

Andreas Marggraf]

The original home of the sugar beet (_Beta vulgaris_) is not definitely known. The plant was found in a wild state in southern and middle Asia and it is said to have been cultivated in southern Europe and northern Africa in olden times. According to Professor Griffin,[19] Herodotus mentions the sugar beet as one of the plants that served to nourish the builders of the pyramids. Dr. von Lippmann cites the same instance and also quotes Voltz as authority for the statement that the Romans first brought the beet into Gaul.

When the beet was originally grown in southern latitudes it was an annual, but when it was taken north it became a biennial, storing sugar the first year and not developing its seed until the second.

Jules Hélot, an eminent French authority, in his “Histoire Centennale du Sucre de Betterave,” says:

“A great French agronomist, called the father of agriculture, Olivier de Serres (1539-1619), was able to find out that the beet-root contained sugar, long before Marggraf set about to extract sugar from this root. Olivier de Serres wrote: ‘The beet-root, when being boiled, yields a juice similar to syrup of sugar, which is beautiful to look at on account of its vermilion color’.”

Dr. von Lippmann, however, contends that Olivier de Serres never claimed in his writings that he discovered the sugar content in the beet, and that the statement “that the boiled juice of the red beet was similar in appearance to sugar syrup” cannot be construed as evidence that de Serres actually recognized the presence of sugar in the beet-root.

In the year 1747 Andreas Marggraf, a chemist and a member of the Royal Academy of Science and Literature of Berlin, demonstrated that various kinds of beet-root contained sugar and that the sugar could be extracted and crystallized. This discovery, however, was regarded for many years as being merely a laboratory determination and without practical value. In 1786 Franz Karl Achard, a pupil of Marggraf, attacked the problem of beet-root cultivation and succeeded in extracting sugar from beets on a scale hitherto unknown. He issued a report of the methods employed and the results obtained and stated that a good muscavado sugar should be made from beets for six cents per pound. His claims met with incredulity and no little ridicule, but the French Institute made a careful investigation of what he had done and found that the sugar content of the beets was over 6 per cent. From a number of tests of Achard’s process, they estimated that the cost of producing refined sugar from beet-roots on a commercial basis would be eighteen cents per pound.

Frederick William III, king of Prussia, took a keen interest in the making of sugar from beets, and, after having convinced himself that Achard was on the right track, he bought the crown land at Cunern, Silesia, for exploitation on a large scale. He provided Achard with funds for the erection of the first real sugar factory built in Germany, at which operations were begun in 1802. The king also supplied money for the construction of other factories in Brandenburg, Silesia, and Pomerania, and lent his support to the growers of beets as well as to the manufacturers of sugar. Despite the reverses in war suffered by the Prussians, the progress in sugar making was so manifest that in 1810 it was clear that the industry was bound to succeed under intelligent management.

[Illustration: DAN SWEENEY

FRANZ CARL ACHARD]

[Illustration: FIRST BEET-SUGAR FACTORY IN THE WORLD—BUILT AT CUNERN, SILESIA, 1802]

Achard, who was of French extraction, had corresponded with a number of scientific men in France and through them reports of his work reached the French Institute. The verdict of this body was favorable and two sugar factories were built, one at St. Ouen and the other at Chelles. Both of these enterprises failed through lack of practical knowledge and the inferior quality of the beet-roots. Although this setback brought the manufacture of beet sugar to a standstill for a time, there is plenty of evidence to show that hope of ultimate success was never abandoned. The effect of the closing down of these two beet factories was to divert the attention of scientists to making sugar from grapes. Proust and Parmentier, both chemists of note, demonstrated that it could be obtained from this source and the French government issued instructions for the preparation of sugar and syrup from the vine. Parmentier published a bulletin advising against the attempt to make beet sugar in France as the soil of the country would not produce beet-roots containing sugar. In 1810 Napoleon ordered an appropriation of 200,000 francs to be divided as a premium among the factories recovering the highest percentage of sugar from grapes. Meanwhile the friends of the beet movement had not been idle, and early in March, 1811, the Society for the Encouragement of National Industry submitted to the emperor a report of what had been accomplished in the manipulation of beets, together with samples of the sugar obtained, and on the 25th of that month Napoleon issued the edict that established the manufacture of beet sugar in France. The decree provided that 79,000 acres of land in various parts of the empire should be devoted to the raising of beets and directed that all the acreage named should be under cultivation the first year, or at latest the second. It created six experimental stations for the instruction of the farmers and land owners in cultivation and also for the furtherance of the interests of the manufacturer.

Delessert had established a factory at Passy in 1801 and by dogged perseverance, despite many failures, obtained excellent results by a new method of clarification and the use of charcoal. Napoleon visited his plant in 1812 and ordered the construction of ten new factories at once. On January 1, 1813, all further imports of sugar from the East and West Indies were prohibited.

In 1812 and 1813 the output of sugar in France was 2200 tons and the factories of Germany and Austria gave promise of soon supplying the wants of their respective countries. During the following two years there were unusually heavy rains and the beet fields of France were occupied by hostile troops. The defeat of Napoleon at Waterloo and the consequent abolition of the blockade caused a decline in the price of sugar to a point where the new beet industry was unable to compete and only one factory succeeded in avoiding the general disaster.

From 1816 to 1821 the average yearly output of beet sugar was 1000 tons. The domestic product had a great advantage over the foreign article, as all sugars coming into France from abroad were subject to a heavy duty, while no tax was levied on home-grown sugar. In 1821, a duty of 49.5 francs was imposed upon every 100 kilograms (220.4622 lbs.) of raw sugar coming from French colonies and 70 francs on white sugar. The tax on sugar from foreign countries was 90 francs per 100 kilograms, and this was increased to 125 francs in 1829.

Shortly afterward the surtax[20] on foreign sugar was increased and an extra duty was exacted on sugar brought into France in foreign bottoms. Even with this protection the domestic producers were not satisfied. French colonial sugar, when exported, received the benefit of customs drawback of 120 francs per 100 kilograms, and the same privilege was accorded home-grown sugar upon which no duty whatever had been paid. This was tantamount to an export premium of 120 francs per 100 kilograms, and it may well be imagined that under this paternal arrangement old factories came back to life and new ones sprang into being. Under this régime by 1836 nearly one-third of the sugar refined in France was beet. The payment of this premium was so great a drain on the government treasury that in 1840 the authorities seriously considered the buying up of all the beet-root sugar factories then in operation for forty million francs and the equalizing of the tax on foreign and domestic sugar. The scheme was not carried out, but in 1843 beet-root sugar and cane sugar were placed on the same basis. This hurt the domestic industry severely, and if it had not been for the setback to the cane production by the abolition of slavery, the beet interests might have met with ruin. Nevertheless, in spite of many adverse turns of fortune, the general trend was forward.

[Illustration: NAPOLEON I]

Beginning with the year 1836, the beet-sugar industry in Germany, which had been paralyzed by the raising of the Continental blockade, went ahead rapidly. The German manufacturers gradually succeeded in obtaining a higher extraction of sugar from the beet and consequently their operations showed an increased profit. Krause of Austria and Schubarth of Prussia, both of whom had studied beet-sugar making in France, did much by their efforts to rehabilitate the industry in Germany, where it has steadily grown in importance ever since.

The manufacture of beet sugar was revived by Austria in 1831 and by 1840 there were many factories in operation. In 1854 the output of domestic sugar equaled the tonnage brought in from foreign countries and beet sugar had established itself throughout Europe as a strong competitor of the cane sugar of the colonies.

The European consumption, however, had grown at such a rate that the domestic beet-sugar production did not keep pace with it, hence the cane manufacturer was scarcely sensible of the competition for some years; in fact Europe took rather more than less cane from the tropics for a time.

During the nineteenth century Europe became less and less dependent upon the cane countries of the New world for its supplies. The abolition of slavery in most of the European possessions (1825-50), the development of the cultivation of cane in India and Java, and the expansion of the bounty-fed beet-sugar industry in Europe all contributed to bring this about and many colonial cane growers found themselves on the brink of ruin.

Slavery, upon which cane sugar raising so greatly depended, was entirely abolished in British possessions in 1834, in France in 1848 during the Second Republic, in the Dutch West Indies in 1863, in Porto Rico in 1873, in St. Thomas in 1876, and in Cuba in 1880. Great Britain appropriated the sum of £20,000,000 sterling as an indemnity, and of this £16,500,000 went to West Indian planters, the remainder going to Mauritius and the Cape, but indemnification, while most welcome, did not restore the supply of labor. Many of the freed slaves refused to work and great numbers of them left the plantations. British colonists were at a serious disadvantage, too, as after their slaves were liberated slavery still existed in other West Indian islands, and to offset this a special import tax was imposed on sugar produced by slave labor.

Strenuous efforts were made to secure an adequate labor supply. Chinese coolies, free negroes and Hindus were tried, but the cost was great and the number available was insufficient for the proper cultivation and upkeep of the plantations. This condition

obtained in the British West Indies, Cuba, Louisiana, Peru, Brazil, the Guianas, Mauritius, Réunion and other places, and the cane growers had hard work to keep from going under during the adjustment period, when they were learning how to operate their plantations with a limited number of hands. Importation of labor, subdivision of cane lands into small tracts, to be rented or sold to farmers—many plans were tried—but naturally under such circumstances development was impossible, and beet sugar, which had been steadily increasing, finally outstripped cane in 1883-84, while in 1899-1900 cane only furnished 34.7 per cent of the world's crop. In 1912-13 the cane tonnage exceeded that of beet by 211,082 tons of 2240 pounds. The great war in Europe has curtailed the production of beet sugar in that country to such an extent that of the world's output for 1915-16 the proportion of cane to beet was roughly as two-thirds to one-third in favor of the former. The actual figures are:

Cane 10,533,039 tons Beet 5,986,404 " ---------- Excess of cane over beet 4,546,635 tons

The following table giving the world's production of cane and beet from 1852 to 1916 will be of interest, but it should be borne in mind that this comparison between beet and cane is not a fair one, because the figures are incomplete as far as cane is concerned.

In some instances in former years, only the quantity exported from a country was included in the world's statistics and the amount consumed at home was left out of the calculations. This is particularly noticeable in the case of India, whose production of over two million tons of sugar annually was omitted from the older estimates as it all went into domestic consumption—while the beet figures were invariably given in full.

The world's crop figures as furnished by Willett & Gray for the period from 1852 to 1916 include British India's production for the last eleven years only:

BEET-ROOT YEAR SUGAR CANE SUGAR TOTAL PER CENT TONS TONS TONS CANE SUGAR

1852-53 202,810 1,260,404 1,463,214 86.0 1859-60 451,584 1,340,980 1,792,564 74.3 1864-65 529,793 1,446,934 1,996,727 73.5 1869-70 846,422 1,740,793 2,586,915 67.3 1874-75 1,302,999 1,903,222 3,206,221 59.4 1880-81 1,820,734 2,027,052 3,847,786 52.7 1883-84 2,485,300 2,210,000 4,695,300 47.0 1884-85 2,679,400 2,225,000 4,904,400 45.4 1885-86 2,172,200 2,300,000 4,472,200 51.4 1886-87 2,686,700 2,400,000 5,086,700 47.1 1887-88 2,367,200 2,541,000 4,908,200 51.7 1888-89 3,555,900 2,359,000 5,914,900 40.0 1889-90 3,536,700 2,138,000 5,674,700 37.7 1890-91 3,679,800 2,597,000 6,276,800 41.2 1891-92 3,480,800 3,501,900 6,982,700 51.6 1892-93 3,380,700 3,040,500 6,421,200 47.3 1893-94 3,833,000 3,561,000 7,394,000 48.2 1894-95 4,725,800 3,531,400 8,257,200 42.7 1895-96 4,220,500 2,839,500 7,160,000 39.6 1896-97 4,801,500 2,841,900 7,643,400 37.2 1897-98 4,695,300 2,868,900 7,564,200 38.0 1898-99 4,689,600 2,995,400 7,785,000 38.5 1899-00 5,410,900 2,880,900 8,291,800 34.7 1900-01 5,943,700 3,646,000 9,589,700 38.0 1901-02 6,800,500 4,079,000 10,880,500 37.5 1902-03 5,208,700 4,163,900 9,372,600 44.4 1903-04 6,089,468 4,244,206 10,333,674 41.0 1904-05 4,918,480 4,613,540 9,532,020 48.4 1905-06 7,217,366 6,733,626 13,950,992 48.2 1906-07 7,143,818 7,334,207 14,478,025 50.6 1907-08 7,002,474 6,912,520 13,914,994 49.6 1908-09 6,927,875 7,634,125 14,562,000 52.4 1909-10 6,587,506 8,339,888 13,927,394 59.8 1910-11 8,560,346 8,421,534 16,981,880 49.5 1911-12 6,820,266 9,066,964 15,887,230 57.0 1912-13 8,976,271 9,232,543 18,208,814 50.7 1913-14 8,908,470 9,879,275 18,787,745 54.3 1914-15 8,241,974 10,165,565 18,407,539 55.2 1915-16 5,986,404 10,533,039 16,519,443 63.7

France held the first place in output of beet sugar until 1880, when Germany took the lead and has maintained it ever since. The beet industry assumed important proportions in Austria-Hungary, Russia, Holland and Belgium shortly after 1850, but it was not established in Sweden, Spain and Italy until comparatively recent times.

The laws that were passed by the various European countries for the encouragement and protection of beet sugar were so beneficial in their effect that these countries not only were able to supply their own domestic demand, but found themselves able to export sugar. This stimulation finally led to abuses, as a result of which the Brussels convention was brought about and the bounties abolished.

Apart from certain details, the various regulations in European countries for the purpose of building up the manufacture of beet sugar and making it a revenue producer were very much alike. The essential features were a prohibitive import duty and a slightly lower excise tax. The latter provided revenue for the government, and the difference between the import duty and the excise shut out foreign competition and fixed the amount of profit the domestic beet-sugar producer could make. Still worse, it created pools or combinations for the control of both output and price.

With increased production, which was more than sufficient to supply the home demand, these countries were in a position to export sugar, and in order to enable their manufacturers to compete in outside markets, a drawback of the excise was allowed on all exported sugar. A peculiar condition of the law affecting this drawback was that it really, though not directly, provided for a bounty on export sugar, and while this was not the original intent of the law, the improvements that it encouraged accomplished the purpose.

In Germany the principle was that the excise was levied upon the quantity of beet-root sliced, while the export drawback was allowed on the actual sugar produced.[21] At the time of the passing of the law that was in operation from September, 1869, to July, 1886, the assumption was that the yield in sugar would be 8.51 per cent of the weight of the beets, allowing 11.75 tons of beets for one ton of sugar, and on all raw sugar exported the manufacturer was given $2.03 per hundredweight drawback, the exact equivalent of the excise tax, which was 17 cents per hundredweight of beets.

For some years after this law became effective it took twelve tons of beets to make a ton of sugar, consequently the drawback allowed the exporter did not represent all of the excise. Thus it became the aim of the manufacturers to raise the sugar content of the beets and to improve the extraction. By 1882 they had succeeded so well that a ton of sugar was produced from 10.46 tons of beet-roots instead of 11.75 tons, as predicated when the law was drawn up. The drawback, however, was still allowed at the rate of $2.03 per hundredweight, which netted the producer a clear gain of 22 cents.[22]

In France from 1864 to 1875 the calculations were made from the quantity and purity of the juice. In other words, a certain arbitrary _rendement_[23] of sugar from the beet-root was the basis of taxation, while any excess recovery was exempt. This was equivalent to an indirect bounty, but the French government saw to it that the estimates and the actual outturn did not get too far apart. No bounty whatever was paid on French sugar from 1875 to 1884.

About 1880 the sugar production of Germany exceeded that of France, so that in 1884 the French authorities revived the indirect bounty system to put new life into the industry, and the effect of this action was soon apparent.

Sugar legislation in other sugar-producing countries of Europe was similar in general principles and gave practically the same results. Amendments were made from time to time with a view to bringing the basis provided for in the law closer to what was actually attained in production, but the manufacturers by constantly improving their processes managed to keep the advantage and consequently to receive a secret indirect bounty or rebate.

The payment of these drawbacks taxed the treasuries of the different countries concerned and in the case of Austria-Hungary amounted to more than the entire revenue from sugar. This brought new regulations and the payment of direct bounties instead of hidden or indirect. Furthermore, a limit was set upon the total that could be paid in any one year.

Nevertheless, the producers in all the sugar-raising countries used their utmost efforts to send as much sugar as they possibly could to foreign markets in order to secure the drawback. It naturally followed that the production was stimulated to an abnormal degree, and toward the end of 1883 there was a slump in prices that affected all raisers of sugar, both beet and cane, throughout the world.

The governments of Europe came to find these bounties a serious burden, and when Lord Salisbury arranged for a convention to be held in London in 1886, the proposal to do away with all bounties met with a good deal of favor. France, however, opposed the idea, as she wished to discontinue the direct bounty only and to leave the indirect still in force, while the British themselves, who used prodigious quantities of sugar and who, under the bounty plan, got all they needed at a price below the actual cost of production, did not wish to forfeit this advantage. So the interests of the British colonists were sacrificed and the London conference accomplished nothing.

In 1890 Germany resolved to divest sugar of all its privileges in order that the treasury should receive the entire amount of the taxes. A measure was proposed in 1891 providing for direct export bounty. This was to be reduced in 1895 and entirely abolished by 1897.

Owing, however, to a severe agricultural crisis at this time, American cereals were brought into Europe at such low prices that the home grower could not compete. It therefore became necessary to find another crop for the land that had been sown to corn and the beet-root was the logical substitute. The increase in beet production from this cause was followed by a crash in sugar prices. With such a condition confronting it, the German government could not do away with, or even reduce, the bounty, especially as none of its neighbors seemed to have any intention of doing anything in this direction. In the interests of the beet growers, the

output of beets in 1895, instead of being restricted as proposed, was doubled, and the export bounty on raw sugar was raised from 1.25[24] marks to 2.50 marks per 100 kilograms and on refined from 2 marks to 3.55 marks per 100 kilograms.

This legislation was meant to foster the export trade and bring the sugar business of foreign countries to German manufacturers, and the framers of the law were confident that other countries would not venture to follow suit. In this they were utterly mistaken. Germany's competitors simply raised their bounties to her figures, thus nullifying her plans for expansion of her export sugar trade.

In 1897 the United States levied a countervailing duty on all bounty-nourished sugar, in addition to the regular protective tariff, so that the bounty paid by European countries on sugar exported to the United States simply went to enrich the United States treasury.

The manufacturers of Germany and Austria enjoyed a profit over and above the bounty by the adoption of what was termed a cartel, or pool, a plan borrowed from Russia.

In Russia the government fixes the amount of sugar required each year for domestic consumption and this quantity may be sold by the manufacturer. Then it determines what quantity shall be kept in reserve, to be sold when the price exceeds that named by the government commission (4.30 rubles[25] per pood[26] in winter, or 4.45 rubles in summer). Should the production exceed the amounts fixed for domestic consumption and reserve, exportation is permitted and the exporter gets back the excise, 1.75 rubles per pood, or if he elects to sell this excess at home, he may do so by paying double tax, or 3.50 rubles per pood. Of the alternatives, exporting the surplus is the more advantageous to the owner of the sugar, as the fixed price for domestic sugar is a profitable one. He therefore can afford to take a loss on the sugar he sells for export and still make money on the total operation. The stipulation that the contingent interest in the profitable home market shall keep pace with the growth of the output of the factory is also a substantial encouragement to manufacturers to increase their production. Regulations like these naturally have the effect of supplying foreign markets with cheap sugar. The manufacturer makes an excellent profit and the domestic consumer pays the entire bill.

Primarily, the intent may have been to keep the price of domestic sugar at one level and to enable the manufacturer to fill the home demand without having to go outside the country for his raw-sugar supply. But the plan in its actual working fosters exportation at the expense of the home consumer.

While in Russia the cartel was a government measure, the pooling of interests by German and Austrian manufacturers in their respective countries accomplished the same end. A cartel formed in Russia in 1890 came to grief after four years through the individual greed of its members. In 1898 a new combination of raw-sugar producers and refiners was formed, with the express proviso that the manufacturers of raws were to sell their product only to refiners who were members of the cartel. The domestic trade in white sugar was prorated among the refiners, in consideration of which they had to allow the producer a fixed price of 30 kronen ($6.08) per 100 kilograms (220.4622 lbs.) for raw sugar, the market price of which was paid by the buyer and the difference by the cartel, which got the money by notching up the price of domestic refined sugar.

With the cartel the only seller of refined, and sugar from foreign countries shut out by the high surtax (the difference between the impost on imported and domestic sugars), the consumer had to pay the price demanded by the cartel as long as the difference between the world's price and that established by the cartel was less than the surtax.

The profit thus obtained constituted a working fund to be used in forcing into line such factory owners as remained outside the pool, either by reducing the price when a factory was about to begin to make white sugar, or by buying stock in the corporations that still held out. Out of the rest of the fund was paid the difference between the market price (with 22 kronen per 100 kilograms as a minimum) and the 30 kronen. Any amount remaining was the cartel's profit. To illustrate and estimating that no kilograms of raw sugar produced 100 kilograms of refined:

Price of refined sugar for domestic use per 220.4 lbs. $17.25 Raw sugar 242.4 lbs. @ $4.46 per 220.4 lbs. $4.91 Refining cost and profit 1.53 Revenue tax 7.71 14.15 ---------- Net profit of cartel $3.10

With an open market price of $4.46 for raws, the difference between that and the arbitrary figure of $6.08 is $1.62 per 220.4 lbs. on 242.4 lbs. 1.78 ---------- Net profit from cartel for refiners $1.32

Reference has been made to the abortive results of the London conference of 1886, when a deaf ear was turned to the appeal of the planters of the British West Indies on account of the advantage to the British manufacturer and consumer of securing all the

sugar they wanted at a figure lower than it cost to produce.

In 1895, Joseph Chamberlain, then Colonial Secretary of Great Britain, appointed a royal commission to investigate conditions in the West Indian colonies. The facts brought out in its report came as a surprise to the statesmen of the mother country and remedial measures were undertaken.

The anxiety of the Austrian and German governments to get rid of the bounty incubus led them to sound France as to her views, and in 1898 the Belgian government invited representatives of Great Britain, Germany, Austria, the Netherlands, France, Russia, Spain and Sweden to meet in conference in Brussels, but no definite agreement was arrived at, chiefly because of France's unwillingness to discontinue the giving of indirect bounty. The meeting adjourned on June 1st with the understanding that it would again convene at the call of Belgium, when the preliminary negotiations through Belgium's good offices had progressed sufficiently to make unanimity possible.

Meanwhile, public opinion in England with regard to the West Indies had undergone a change, partly on account of the report submitted by the Chamberlain commission and partly owing to the fact that Britain, needing the support of her colonies in her South African war, was anxious to shape her policy to please them.

A third conference was held in Brussels in December, 1901.

In the discussion concerning the German and Austrian cartels, it had developed that the heavy surtax permitted the Germans and Austrians to realize such high prices in their home markets that, even with the bounty repealed, their overproduction was very great and the large tonnage exported by them depressed values in foreign markets. Great Britain and Belgium, therefore, demanded that the surtax be reduced to a point where, while giving protection against foreign sugar, it would afford no inducement for the formation of cartels. Austria and Germany demurred to this and it looked as if a deadlock would again be reached, when Great Britain declared that if nothing came of the conference a measure would be introduced in Parliament excluding bounty-fed sugars entirely, or that some action equally drastic would be taken. It was further pointed out that an extra duty of an amount equal to the cartel profit had already been under consideration by the Indian government.

With a countervailing duty effective in the United States, the market of Great Britain was the only important outlet left for bountied export sugars from the Continent. Then again, the British colonies had to be reckoned with, for if preferential privileges were accorded to their sugars Continental beet would suffer. Great Britain's ultimatum, therefore, carried the day, and on March 5, 1902, the convention was signed by the plenipotentiaries of Great Britain, France, Germany, Austria, Belgium, Spain, Italy, the Netherlands, Norway and Sweden.

The most important provisions of the convention were:

1. The suppression of all bounties, direct or indirect.

2. The limitation of the surtax, _i. e._, the excess of import duty over domestic revenue tax, to 53 cents per 100 pounds on refined and 48 cents per 100 pounds on raw sugar.[27]

3. Prohibition of importation of bounty-fed sugar from other countries, unless a countervailing duty is imposed.

4. Great Britain and the Netherlands pledge themselves that no preferential treatment will be given sugar from their colonies during the life of the agreement.

5. The agreement to come into force September 1, 1903, and to remain effective for five years from that date, and in case none of the signatory powers notifies the Belgian government of its intention to withdraw, it shall continue to remain in force for one year and so on from year to year.

6. The appointment of a permanent commission charged with supervising the execution of the provisions of the convention.

7. Spain, Italy and Sweden not to be bound by the principal restrictions, so long as they do not export sugar.

Russia declined to come into the pact, stating as her reason that she paid no bounty.

Great Britain's action in joining the Brussels convention aroused a good deal of feeling at home. The contention was made that it worked an injury to the British consumer in causing an advance in prices; it was also argued that the plea put forth in behalf of the West Indies was really instigated by the selfishness of British investors in colonial sugar plantations. The rise in price that followed

the convention was stimulated by the shortage in the European beet crop in 1904, and provoked much agitation and dissatisfaction in England, so that it was not certain that Great Britain would be a party to a renewal of the pact upon its expiration.

Subsequently Peru, Luxembourg and Switzerland joined the convention, and the contracting parties were so well satisfied with results obtained that they extended the agreement for five years beginning September 1, 1908. The conditions were to remain unchanged, except for an amendment that permitted Great Britain to disregard the article that prohibited the importation of bountied sugar, unless paying countervailing duty. This prohibition directly affected Russian sugars, of which England did not wish to be deprived.

Russia joined the convention in 1908, with the understanding that her existing fiscal laws and excise regulations should not be interfered with and that the method of fixing the price of sugar for home consumption should rest undisturbed. On her part, Russia undertook not to export more than one million tons during the next five years outside of Finland, Persia and neighboring Asiatic countries.

The convention with these modifications was thus extended to September, 1913, and on March 15, 1912, it was agreed to prolong it until August 31, 1918, on practically the same conditions as the 1908 convention. Because of the great drought in central Europe in the summer of 1911, there was a shortage of 2,000,000 tons in the beet-sugar crop of 1911-12, as compared with the former year, and, on account of the consequent rise in price, England demanded that the Russian exports be increased. The other signatory powers agreed to this and the amount that Russia was permitted to export in the seven years beginning September 1, 1911, was fixed at 1,650,000 tons.

In August, 1912, Sir Edward Grey gave notice of Great Britain's intention to retire from the convention on September 1, 1913, and on that date she ceased to be a party to it. Nevertheless, after her withdrawal she undertook to observe all the obligations of the convention, and in return the signatory powers agreed not to discriminate against her manufactures of sugar.

The convention stopped exportation of beet sugar at abnormally low prices. It was instrumental in lowering the revenue tax, increasing the consumption and abolishing artificial conditions.

The outbreak of the war in Europe in August, 1914, interrupted the operations of the convention, and it remains to be seen whether or not, when hostilities come to an end, it will be renewed and its terms reaffirmed according to procedure customary when peace is concluded between warring nations.

As soon as the industry got on a sound basis, cane began to feel the benefit of the new order of things. Factories that had been closed were put in operation again and new enterprises were undertaken. Up to the year 1880 the manufacture of cane sugar had been conducted in a slipshod manner. The planters were lavishly extravagant and spent their incomes as they made them, giving no thought to putting aside funds for extensions and betterments. Hard times taught them a severe lesson, by which they profited, and with admirable courage they bent all their energies to the improvement of methods of cultivation and cutting down the cost of production. This was particularly true of Java; beginning with 1884, abundant new capital was brought in, experimental stations and laboratories were built and equipped and all that scientific knowledge, energy and sound business judgment could do was done. At the same time Hawaii, Mauritius, Porto Rico and Cuba made extraordinary progress, but each of these countries deserves an individual chapter.

BEET SUGAR IN THE UNITED STATES

While the manufacture of sugar from beet-roots is one of the foremost industries in the United States today, the early stages of its growth and development were marked by numerous failures and setbacks. The first beginning was made by a company headed by John Vaughn and James Ronaldson, which built a small factory in Philadelphia in 1830, where a few hundred pounds of sugar were produced. Owing to lack of knowledge of beet culture and extraction of sugar from the roots, the venture proved unsuccessful and no further attempt has been made in Pennsylvania.

Northampton, Massachusetts, was the scene of the next experiment in 1838 and 1839 by David Lee Child, who had studied the growth and manufacture of beet sugar in Europe for a year and a half. He succeeded in getting 6 per cent of sugar and 2½ per cent of molasses from the beets and his estimate of the cost of the sugar per pound was eleven cents. After producing 1300 pounds of sugar he abandoned the enterprise.

A report made in 1838 by the Committee on Agriculture, a government body, contains the following statement: “From all the information which the committee have been able to obtain, they are induced to believe that no country in the world is better adapted for the production of sugar beets than most parts of the United States, whether we consider the soil, the climate or the people.”[28]

In 1851 John Taylor, who afterward succeeded Brigham Young as president of the Mormon church, was carrying on missionary work in England, and in September of that year he met Elias Morris, whom he engaged to go to Utah to establish a plant for the manufacture of beet sugar.

Machinery for the purpose was purchased in France and sent to Liverpool, from where it was shipped to New Orleans in charge of Morris in March, 1852. From New Orleans it was taken up the Mississippi river to St. Louis, thence to Kanesville, Ohio, where it was loaded on wagons for transportation across the plains. The journey from the river was begun on July 4th, with oxen as the motive power. It proved long and arduous, but the members of the party reached Green river, Wyoming, four months later, having suffered much from hunger and cold. There they were met by a detachment sent out from Salt Lake city by Brigham Young and they finally arrived at their destination about the middle of November.

The original intention was to start operations at Provo, and the sugar machinery was taken there, but the company that John Taylor had organized was dissolved and the machinery turned over to the church, under whose direction it was installed in an adobe building still standing in Salt Lake city.

Once more lack of knowledge resulted in failure. Instead of sugar, the Mormons only succeeded in making a massecuite that was utterly inedible.[29]

In 1856, a coppersmith named Bepler erected a small beet-sugar factory at Ocean View, near San Francisco, California, but the enterprise was unsuccessful.[30]

The next noteworthy attempt was made at Chatsworth, Illinois, in 1863 by the brothers Gennert, who came from Braunschweig, Germany, and who were familiar with the methods of beet-sugar making. They formed the Germania Beet Sugar company, planted a thousand acres of land in beets and sent to Europe for machinery, but their highest extraction of sugar from the beet-roots was only 5.5 per cent. Weather conditions were unfavorable and the soil they selected was not suited to beet culture, so six years of effort ended in failure and the loss of more than a quarter of a million dollars. The plant was removed to Freeport, Illinois, where the final result was disaster.

Otto and Bonesteel, two Germans, established a factory at Fond-du-lac, Wisconsin, in 1866,[31] and during the two following years they achieved some measure of success. Subsequently, they moved to Alvarado, California, where they began operations in 1870. They managed to keep their factory running for a few years, but finally gave up the struggle in 1876.

In 1872 the state of New Jersey passed a law providing that all capital and property employed in the raising of sugar beets should be free from taxation for ten years. New ventures were undertaken in California, Delaware and Maine, and these states stimulated the industry by bounties, or tax exemption, or both. A factory was built at Hartford, Maryland, in 1879, but it was afterward abandoned, and the only going concerns engaged in the manufacture of beet sugar east of the Alleghanies during recent years were the small plants in New York at Rome and Lyons. Dismantled in 1905 and 1911, respectively, part of the machinery of the former was moved to Visalia, California, and the latter plant in its entirety to Anaheim, California.

All of these failures were traceable to the lack of practical knowledge of beet culture and the making of sugar from beet-roots. Then, too, the agricultural lands at first selected were unsuited to the purpose and the seed used up to the year 1890 gave beets of a low sugar content, from 6 per cent to 8 per cent. The development of the Western states gave the beet-sugar industry a permanent place in California, and a little later in Utah, Colorado, Idaho, Montana and Wyoming.

[Illustration: BUILDING IN SALT LAKE CITY, UTAH, IN WHICH THE FIRST BEET-SUGAR MACHINERY BROUGHT TO THE WEST WAS INSTALLED]

[Illustration: E. H. DYER. THE FATHER OF BEET SUGAR IN AMERICA]

The California Beet Sugar Manufacturing company was organized by E. H. Dyer and C. S. Hutchinson in 1869 with $250,000 capital and a factory was erected at Alvarado on Mr. Dyer’s ranch. Otto and Bonesteel were induced to leave Fond-du-lac, Wisconsin, and come west to assume the management. Operations were begun in 1870 and on November 17th of that year the first beet sugar was made in California. The factory and equipment cost $125,000; the daily capacity was fifty tons of beets and one

hundred and twenty-five men were employed. Between one thousand and fifteen hundred acres were planted in beets, the factory paying $3.50 per ton for them. The finished product cost about ten cents a pound, while the market price ranged from twelve to fifteen cents a pound. The first year's output was 250 tons, the second 400 tons, the third 562 tons and the fourth 750 tons. Then financial troubles came and the plant was closed. The machinery was sold to a new concern, which built a factory at Soquel, Santa Cruz county. This enterprise failed in 1876, but the plant was put in operation again in 1880, when 150 tons of sugar were produced. That was the end of the Soquel venture.

In 1879 Mr. Dyer bought the buildings and land of the old California Beet Sugar Manufacturing company, and, with O. F. Giffin, formed the Standard Sugar Manufacturing company, with a capital of $100,000. Subsequently a reorganization was effected under the name of the Standard Sugar Refining company and the capital was increased to $200,000. The machinery and diffusion batteries of a plant built at Brighton by some Sacramento people about eight years previous were purchased and installed at Alvarado in buildings newly erected for the purpose. While it is true that in the operation of this company there was a constant struggle to overcome obstacles and difficulties, it is nevertheless a fact that it achieved success from the beginning. In 1884 the capacity of the mill was increased to 100 tons of beets per day, but disaster overtook the concern toward the end of 1886. Two of the boilers exploded, making it impossible to operate during the season of 1887-88.

Nothing daunted, Mr. Dyer grappled with the problem once more and succeeded in floating a new corporation, the Pacific Coast Sugar company, with $1,000,000 capital and headed by John L. Howard as president. In 1887 and 1888 this company built the middle part of the present factory at Alvarado, where it installed most of the machinery from the old plant, together with some new apparatus. The campaign of 1888 was barren of results and in March of the following year the Pacific Coast Sugar company sold its property to a new concern, the Alameda Sugar company, whose first president was M. H. Hecht. In 1890 two additions to the factory were built, one at each end.

From small beginnings, this Alvarado enterprise, the pioneer of American success in the production of sugar from beets, continued its yearly operations from 1879 until 1914, with the exception of the year following the boiler explosion. In 1889 the output was 872 tons, in 1911 it reached 9966 tons. At the beginning of 1914, sugar prices were low and tariff prospects very discouraging. Under such conditions, the owners of the plant did not believe that they could make sugar at a profit, and the factory remained closed during that season. The sharp advance in sugar values, due to the war in Europe, completely changed matters; beets were planted and 6363 tons of sugar were produced in 1915.

For a long time Mr. Dyer was looked upon as an enthusiast and a dreamer whose sincerity was unquestioned, but whose energies were misdirected. In the midst of the gloomy forebodings of those around him, he held tenaciously to his purpose and devoted his brains and his money to the solution of the problem confronting him. That the beet-sugar industry of the United States proved a success when it did is due to his unfailing courage and persistent effort.

A year before the Alvarado factory was built, a number of moneyed men of Sacramento, head by Julius Wetzlar, then president of the Capital savings bank, conceived the idea of starting a beet-sugar plant there. After some experimenting with local beets, the Sacramento Valley Sugar company was organized and machinery for a seventy-ton plant was ordered from Germany. Construction was delayed for a year, and thus the Sacramentans lost the honor of being the first in the field. In 1871 they built a factory at Brighton, six miles east of Sacramento, near the American river. An expert was brought out from Germany and work was begun on November 18th. The first diffusion battery used in the United States was employed in the extraction of sugar from the beets. The season of 1871 gave good results, but the following year the crop suffered greatly from the ravages of the army worm. The campaign of 1873 opened on August 5th, lasting until November 22nd. The yield of beets was ten tons per acre, the average sugar content 8 per cent and the total output 982,120 pounds of sugar, including all grades.

This enterprise struggled along until 1875, in spite of troubles from drought, army worm, grasshoppers and last, but not least, lack of experience. The plant was then closed and the equipment put up for sale. Briefly, it may be said that at the outset very poor sugar was turned out, and later, when the quality was improved, the cost of manufacture was found to be greater than what the sugar would bring. The final outcome was that the stockholders lost nearly all the money they had invested.

About 1874,[32] the California Sugar Manufacturing company was formed. Sixty-eight acres of land at Isleton were bought, a factory structure of brick was erected and machinery installed, the total expenditure being about $250,000. Sugar of good quality was made, but the financial result was disastrous. Isleton land was ill suited to beet culture, as when the Sacramento river was high the beet fields were covered with water. One authority states that the original idea was to manufacture sugar from watermelons,

and when it was found that this was not practicable, attention was turned to beets.

In 1876 numerous mechanics' liens were filed against the company. Later, the factory was leased to H. M. Ames of Oakland, who operated it during the campaign of 1880. Two years afterward the entire plant was sold at sheriff's sale for $10,000. The land and building were purchased by P. H. Gardiner of Isleton and the machinery went to a San Francisco junk dealer. This venture is said to have caused financial distress to many of the farmers in the vicinity.

In 1888, Claus Spreckels, so long a prominent figure in the sugar world, established a beet factory at Watsonville, Santa Cruz county, in the rich Pajaro valley. At first its capacity was 300 tons of beets per day, and, the result of the operations being favorable, this was increased from time to time until it reached 1000 tons of beets per day. The Watsonville factory developed into the largest beet plant in America and remained so until 1898, in which year Mr. Spreckels erected a modern 3000-ton plant at Salinas, fifteen miles distant. Since then the new factory has sliced all of the beets grown in that territory and the old one has been dismantled. The capacity of the Salinas plant now is greater than that of any other beet factory in the United States, being 4000 tons per day.

The Oxnard brothers, Henry T., Benjamin, James G. and Robert, with J. G. Hamilton, W. Bayard Cutting and R. Fulton Cutting, organized the Oxnard Beet Sugar company in 1889, and in December of that year broke ground for a beet-sugar factory of 350 tons slicing capacity at Grand Island, Nebraska. In 1891 they built two more, one at Norfolk, Nebraska, and one at Chino, California, both of the same size as the Grand Island plant. The machinery for the first two factories was bought in France and that for the last one came from Germany. Toward the end of 1897, construction at Oxnard was begun, and in 1899 a consolidation of all these factories was effected under the corporate title of the American Beet Sugar company.

At the close of 1890, sixty years after the first experiment at Philadelphia, there were only three beet-sugar factories in operation in America; those at Alvarado, Watsonville and Grand Island. The total capacity of the three plants was eight hundred tons of beets a day, or ten thousand tons of sugar a year. France in the same period increased her production from 5000 to 770,000 tons a year through favorable legislation providing for the payment of bounties.

In the United States, whenever beet-sugar enterprises have been started, there has generally been some legal provision for payment by the state of bounty on the quantity of sugar produced. The story of how this responsibility was evaded is hardly a pleasant one. In Nebraska, for example, three different legislatures enacted laws providing for bounty on beet sugar, but in each case the following legislature either repealed the act or failed to make appropriations for the necessary funds. In the early nineties, Michigan passed a bounty law which resulted in several beet factories being established in that state, but when the claims for bounty were presented for payment, the state auditor refused to honor them, and his action was upheld by the state supreme court on the ground of unconstitutionality. A similar condition arose in Idaho. Minnesota paid bounties in 1890 and 1899, after which the law was declared unconstitutional.

The McKinley bill of April, 1891, was the first national legislation to encourage the beet industry. It called for a bounty of two cents on each pound of domestic sugar produced testing over 90 degrees, and admitted beet seed and sugar machinery free of duty. This encouraged the Oxnards to build the factories at Norfolk, Nebraska, and Chino, California, of which mention has already been made. At the same time Thomas R. Cutler and his associates put up a beet factory at Lehi, Utah, which state offered a bounty in addition to that granted by the Federal government.

The tariff act of August 28, 1894, abolished the bounty on sugar and fixed an ad valorem duty of 40 per cent. As a result of the loss of the bounty and the financial stress that reigned at that time, no beet factories were started except that at Menominee Falls, Wisconsin, which was a flat failure.

The following résumé of the United States tariffs on sugar since the year 1846 may be found useful for purposes of reference:

Tariff act July 30, 1846: All sugars 30 per cent ad valorem.

Tariff act March 3, 1857, to be effective from and after July 1, 1857: All sugars 24 per cent ad valorem.

Tariff act March 2, 1861, effective April 1, 1861: ¾c per pound on raw, 2c per pound on refined.

Tariff act August 5, 1861: 2c per pound on raw. Sugars above 12 D. S. and not yet refined, 2½c per pound. 4c per pound on refined.

Tariff act July 14, 1862, effective August 1, 1862: Sugars not above 12 D. S., 2½c per pound. Sugars above 12 D. S., not above 15 D. S., 3c per pound. Above 15 D. S., not above 20 D. S., and not stove dried, 3½c per pound. Refined and above 20 D. S., 4c.

Joint resolution of April 29, 1864, in effect for sixty days: Sugars not above 12 D. S., 2½c per pound plus 50 per cent equals 3¾c per pound. Sugars above 12 D. S. and not above 15 D. S., 3c plus 50 per cent equals 4½c per pound. Sugars above 15 D. S. and not above 20 D. S., 3½c per pound plus 50 per cent equals 5¼c per pound. All refined sugars 4c per pound plus 50 per cent equals 6c per pound.

Tariff act June 30, 1864, effective July 1, 1864: Sugars not above 12 D. S., 3c per pound. Sugars above 12 D. S., not above 15 D. S., 3½c per pound. Sugars above 15 D. S., not above 20 D. S., and not stove dried, 4c per pound. All refined sugars and all sugars over 20 D. S., 5c per pound.

Tariff act July 14, 1870, to be effective on and after December 31, 1870, which means January 1, 1871. Later amended by tariff act of December 22, 1870, to be effective immediately: Sugars not above 7 D. S., 1¾c per pound. Sugars above 7 D. S., not above 10 D. S., 2c per pound. Sugars above 10 D. S., not above 13 D. S., 2¼c per pound. Sugars above 13 D. S., not above 16 D. S., 2¾c per pound. Sugars above 16 D. S. and not above 20 D. S., 3¼c per pound. All sugars above 20 D. S. and all refined, 4c per pound.

Tariff act March 3, 1875: Sugars not above 7 D. S., 1¾c per pound plus 25 per cent equals 2.19c per pound. Sugars above 7 D. S., not above 10 D. S., 2c per pound plus 25 per cent equals 2.50c. Sugars above 10 D. S., not above 13 D. S., 2¼c plus 25 per cent equals 2.81c per pound. Sugars above 13 D. S., not above 16 D. S., 2¾c plus 25 per cent equals 3.44c per pound. Sugars above 16 D. S., not above 20 D. S., 3¼c plus 25 per cent equals 4.06c per pound. All sugars above 20 D. S. and all refined sugars, 4c per pound plus 25 per cent equals 5c per pound.

Tariff act March 3, 1883, effective June 1, 1883: Sugars not above 13 D. S. and not above 75-degree polarization, 1.40c per pound and .04c additional per degree or fraction thereof. Sugars above 13 D. S., not above 16 D. S., 2.75c per pound. Sugars above 16 D. S., not above 20 D. S., 3c per pound. Sugars above 20 D. S., 3½c per pound.

Tariff act October 1, 1890, effective April 1, 1891 (McKinley bill): Bounties effective July 1, 1891. Bounties declared unconstitutional by the United States supreme court: Bounty on domestic productions, sugars testing 80 degrees to 90 degrees, 1¾c per pound. Bounty on domestic productions, sugars testing at least 90 degrees, 2c per pound. All sugar not above 16 D. S., free. All sugar above 16 D. S., duty ½c per pound. All sugar above 16 D. S. from bounty-paying countries, duty ■/■■c per pound.

Tariff act August 27, 1894, effective August 28, 1894 (Wilson bill): Bounty on domestic production repealed. All sugars 40 per cent ad valorem. All sugars above 16 D. S. and all sugars discolored, 40 per cent and ■c per pound. All sugars from bounty-paying countries, ⅛■■c per pound additional.

Tariff act July 24, 1897 (Dingley bill): Raws not above 16 D. S. and not above 75-degree polarization, .95c per pound. Each additional degree or fraction thereof, .035c per pound additional. Sugar above 16 D. S. and all refined, 1.95c. All sugars from bounty-paying countries, countervailing duties equal to bounties additional.

Tariff act August 5, 1909 (Payne-Aldrich bill): Raws not above 16 D. S. and not above 75-degree polarization, .95c per pound. Each additional degree or fraction thereof, .035c per pound additional. Sugar above 16 D. S., and all refined, 1.90c per pound. All sugars from bounty-paying countries countervailing duties equal to bounties additional.

Tariff act October 3, 1913, effective March 1, 1914 (Underwood bill): Raws testing not above 75-degree polarization, .71c per pound. Each additional degree or fraction thereof, .026c per pound additional. No. 16 D. S. clause repealed. All Philippine sugars to be admitted free. After May 1, 1916, all sugars to be admitted free of duty.

In April, 1916, a bill was passed by Congress repealing the free-sugar clause of the tariff act of October 3, 1913. The President signed the bill on April 27, 1916.

The Democratic party was defeated in 1896 and the following year saw the passage of the Dingley bill, which levied a duty of 1.685 on 96-degree raw centrifugals under 16 D. S. in color and 1.95 on raws over 16 D. S. and on refined sugars. Under the beneficial influence of this law the industry revived and within a period of about two years from the enactment of the bill twenty-four beet factories sprang into being. One-half of the number were unsuccessful[33] because the stimulating provisions of the new tariff caused ventures to be made hastily and without regard to actual conditions. Of the twelve factories that survived, nearly all were situated in California and Michigan.

From 1900 to 1902 the building of beet plants was not so rapid, for the reason that the failures just mentioned and the popular demand for preferential terms for Philippine and Cuban sugars were not exactly encouraging. A 25 per cent preferential was given to Philippine sugars March 8, 1902, and a concession of 20 per cent of the duty was allowed Cuba December 27, 1903; still, notwithstanding the failures and the political agitation, five or six beet factories were erected each year during this period. The number of beet factories operating in the United States in 1915 was sixty-seven and the total daily slicing capacity was 73,320 tons. The acreage harvested was 611,301 acres, ninety-three per cent of which was worked by independent farmers and seven per cent by the factories. The total amount of beets sliced during that season was 6,150,293 short tons, which produced 874,220 short tons of sugar.

The following is a list of the factories themselves:

TERRITORY OF HAWAII

The Hawaiian islands lie in the north Pacific ocean, between 18 degrees 54 minutes and 22 degrees 15 minutes north latitude and 154 degrees 50 minutes and 160 degrees 30 minutes west longitude. The group consists of eight inhabited islands and a number of small barren islets extending several hundred miles in a west-northwesterly direction.

The area of the various inhabited islands in square miles is as follows:

Hawaii 4210 Maui 728 Oahu 600 Kauai 547 Molokai 261 Lanai 139 Niihau 97 Kahoolawe 69 ---- Total 6651

All of them are of volcanic and comparatively recent origin, and their age, or at least the time since the last eruptions on them, decreases from west to east. On Hawaii, the largest and most easterly of the group, the volcanic forces are still active and its surface is covered with lava thrown up at no very remote period. The principal port is Hilo and the highest mountain peaks are Mauna Kea (White mountain), 13,823 feet, and Mauna Loa (Great mountain), 13,675 feet.

Maui is formed by two mountains connected by an isthmus. Mauna Haleakala, the higher of the two, rises to a height of 10,032 feet.[35] Kahului is the most important town and seaport.

Oahu is of irregular quadrangular shape. Two nearly parallel mountain ranges traverse it from southeast to northwest and between them is a plateau that slopes down to the sea both in a northerly and southerly direction. The principal port is Honolulu, the “cross-roads of the Pacific,” a flourishing city of about 60,000 inhabitants and the capital of the group. It is admirably situated on a fine harbor and, in addition to its commercial importance, is one of the most attractive spots in the world on account of its balmy climate and wondrously beautiful surroundings. It is strongly fortified and a considerable military force is maintained there.

Pearl Harbor lies about seven miles from Honolulu in a westerly direction. Here the United States government has established a great naval station, one of the finest in existence. It has the most improved apparatus for supplying coal or fuel oil to vessels; there are machine shops, storehouses and barracks; and the huge dry-dock when completed will accommodate the largest dreadnaughts. The entrance from the sea has been dredged to make it navigable for ships of the greatest draft and the station is protected by powerful long-range guns of the most modern type.

Kauai, the oldest island of the group, is irregularly circular in shape, with a maximum diameter of about 25 miles. On the northwest a precipice rises to a height of 2000 feet and beyond that is a mountain plain, but the other portion of the island consists of shore plains with the mountain peak, Waialeale, 5250 feet high, in their midst. The shore plains are broken by ridges and broad, deep valleys and the island is well watered on all sides by mountain streams. There are a number of ports, but no large towns.

The climate of the Hawaiian islands near sea-level does not vary greatly from one year's end to the other. It is cooler than other regions in the same latitude and extremely healthful. The northeast trade winds blow with periodic variations from March to December, or, as one writer says, 264 days out of 365 every year.[36] The leeward coast, protected by high mountains, is refreshed by regular land and sea breezes. The heaviest rainfall is from January to May, and naturally the greatest precipitation takes place on the windward side of the principal islands. The extremes of local rainfall in the larger islands have been known to range from 12 inches to 300 inches for the year. In Honolulu the average temperature runs from 72 degrees to 74 degrees, the maximum about 88 degrees and the minimum 52 degrees Fahrenheit. In ascending the mountains a lower temperature will be encountered as a matter of course and some of the highest mountain peaks are covered with snow nearly all the year round. Winds seldom blow with extreme violence and hurricanes are unknown.

Singular it is that so little should have been written upon a subject so important as the history of the growth of the sugar industry of the Hawaiian islands. Jarves and Thrum bring the narrative down to 1875 and Mr. H. P. Baldwin, in his book entitled "The Sugar Industry in Hawaii" (1895), contributes a fund of valuable information which is freely drawn upon in this chapter.

Tradition has it that a Japanese junk touched at the island of Maui during the thirteenth century and a Spanish vessel is said to have put in on the south coast of Hawaii during a voyage from Mexico to the Philippines in 1550. Be this as it may, our knowledge of these islands dates only from the time of their discovery by Captain Cook in 1778. He found sugar cane growing there when he landed and speaks of it in his description of his first visit as being "of large size and good quality." According to the old natives, it grew wild and luxuriant in the valleys and lowlands. As far back as 1837 Mr. D. D. Baldwin recalls having seen fields of white cane on the edge of the woods at Hana, Maui, at an elevation of 2000 to 3000 feet. The natives made no attempt to use sugar cane except as an article of food, although it is said that in ancient days it served as an offering to their gods, particularly the god "Mano" (shark).

Cleveland[37] says that upon his first visit to the Sandwich group in 1799 the natives came alongside the ship in canoes bringing many fruits and vegetables, among which was sugar cane.

L. L. Torbert, one of the early planters, in a paper read before the Royal Agricultural Society in January, 1852, claims that the earliest sugar factory was put up on the island of Lanai in 1802 by a Chinaman who came to the islands in one of the vessels trading for sandalwood. He brought with him a stone mill and boilers, and after grinding one small crop and making it into sugar, went away the next year taking his apparatus with him.

Anderson[38] makes a statement that 257 tons of sugar were exported from the islands in 1814, but cites no authority upon which to base his assertion.

According to Jarves[39] the first instance of the manufacture of sugar goes back beyond 1820, but the name of the pioneer planter is unknown. It is certain that at first molasses was manufactured and then sugar some time before 1820.

Don Francisco de Paula Marin made sugar in Honolulu in 1819, the year before the arrival of the first missionaries. Lavinia, an Italian, did the same thing in 1823. His method was to pound the cane with stone pestles on huge wooden trays (poi boards) by native labor, collecting the juice and boiling it in a small copper kettle.

Accounts from various sources agree that the making of sugar and molasses was general in 1823-24. This undoubtedly had direct connection with the manufacture of rum, which was extensively carried on at that time.

In 1828 a considerable amount of cane was raised in the neighborhood of Honolulu and mills were built in the Nuuanu valley and Waikapu, Maui. A pioneer cane grower, Antonio Silva by name, lived at the latter place, and some Chinamen had a sugar mill near Hilo. In those days mills were made of wood, very crudely put together and worked by oxen.

The first attempt at sugar cultivation on a large scale was made at Koloa, Kauai, by Ladd & company, a Honolulu merchant firm, in 1835. This was the beginning of what is now known as the Koloa plantation, and the first breaking of the soil for planting cane was done with a plough drawn by natives. A mill was established here at the same time, and the enterprise was managed by a Mr. Hooper.

As has been said, the general character of the mills was rude and primitive and it continued to be so up to 1850. The rollers were generally of wood and the kettles in which the juice was boiled were whalers' trypots. The buildings were adobe or simple grass huts. Only one grade of sugar was made. The juice was boiled to a thick syrup and put into coolers to grain, after which the granulated mass was packed in mats, bags, boxes or barrels with perforated bottoms for the molasses to drain off. The mills were run by bullocks, horses and in some cases by water power, and were fed by hand, one stalk at a time. The whole process, both in the field and in the mill, was very crude and imperfect.

The value of the sugar exported from the islands from 1836 to 1841 was $36,000 and that of the molasses for the same period $17,130.

An article by the late William Ladd on the "Resources of the Sandwich Islands," published in the "Hawaiian Spectator" for April, 1838, speaks thus prophetically of the manufacture of sugar, then in its infancy:

"It is a very common opinion that sugar will become a leading article of export. That this will become a sugar country is quite evident, if we may judge from the varieties of sugar cane now existing here, its adaptation to the soil, price of labor and a ready market. From experiments hitherto made, it is believed that sugar of a superior quality may be produced here. It may not be amiss to state that there are now in operation, or soon to be erected, twenty mills for crushing cane propelled by animal power, and two by water power."

Just here it may be remarked that at that time the price of labor was a potent argument in favor of making the islands a sugar-producing country, for native labor was available in abundance and the current rate of wages was from 12½ cents to 37½ cents per day, or $2.00 to $5.00 per month.

In an article on commercial development,[40] Thrum says:

"Hawaiian produce in the early days had to seek distant markets, for we find shipments of sugar, hides, goat skins and the first shipment of raw silk moving to New York per the bark _Flora_ in 1840. A trial shipment of sugar was sent to France, but it did not offer sufficient encouragement for any renewals. The Sydney market was also exploited with sugar, where it obtained better figures than similar grades of Mauritius."

Between the years 1840 and 1850 a cane field and rude mill in Lahaina, Maui, were owned by David Malo, a well-known Hawaiian, who made molasses and sold it for home consumption. His apparatus consisted of three whaling-ship trypots set up on adobe and stone mason work. The crushing was done with wooden rollers, strengthened by iron bands.

In 1841, Kaukini, governor of Hawaii, planted about one hundred acres of cane in Kohala and the crop when harvested was ground under contract by a Chinese named Aiko.

In Wyllie's "Notes" on the islands, published in the "Friend," December, 1844, the quantity of sugar exported from the island of Kauai is estimated at about 200 tons, and the molasses at 20,000 gallons. Hilo, in the same year, exported 42 tons of sugar. Maui had, at that time, two mills, but the amount of sugar produced is not reported.

In 1851, D. M. Weston, then manager of what is now the Honolulu Iron Works, invented the first centrifugal machine for drying sugar, and this machine was installed on the East Maui plantation in the same year. This, it is claimed, was the first centrifugal to be used for the purpose anywhere.

Prominent among the early planters are the names of Stephen Reynolds, William French, Ladd & company, Dr. R. W. Wood, L. L. Torbert, W. H. Rice, and later on S. L. Austin, A. H. Spencer and Captain Makee.

In the year 1854 or 1855, Captain Edwards of the American whaler _George Washington_ brought from Tahiti two varieties of cane, one known as Cuban and the other as Lahaina. The latter proved to be profitable to raise and fifteen or sixteen years later began to displace other species throughout the islands. Since then its popularity continued to increase and up to twenty years ago it was the variety most in favor on all Hawaiian plantations.

Twelve varieties of cane were imported from Queensland, Australia, in 1880, but of these only one—the Rose Bamboo—compared with the Lahaina in productiveness, and that only in high altitudes.

In 1898 Lahaina and Rose Bamboo seemed to have outlived their usefulness on the Hamakua coast of the island of Hawaii, and while they continued to give excellent results in the low, sheltered valleys, it became evident that they could not be profitably grown on the uplands. The yields in the Hamakua region were becoming smaller each year and the plantation owners had to seek a new variety. A cane known as Yellow Caledonia[41] solved the difficulty and wonderful crops of it have been raised uninterruptedly in that section ever since.

In 1856 no fertilizers were used and practically nothing was known of irrigation. The average yield of sugar at that time was one ton per acre. The extraction of sugar from the cane was less than 50 per cent, while today in the best mills it exceeds 98 per cent and the average result from all Hawaiian factories shows over 90 per cent.

The industry struggled along under severe handicaps and discouraging circumstances until 1857, when the number of plantations on the islands had dwindled down to five: Koloa and Lihue on Kauai, the East Maui and the Brewer on Maui and a Chinese outfit near Hilo, Hawaii.

In 1858-59 steam was adopted as the motive power in the mills; wooden mills were superseded by those built of iron and in 1861 the first vacuum pans were introduced. The same year saw the number of plantations increase to twenty-two, nine of which employed steam for the grinding of the cane.

The outbreak of the Civil war in the United States cut off the supply of sugar drawn from the Southern states and caused the price of Hawaiian sugar in kegs to advance to ten cents a pound. This gave the Hawaiian producers their first real start. In 1863 the export tonnage was 2600, and this increased until in 1860 it reached 8869 tons.

A small plantation was started at Paia, Maui, by a Captain Bush in 1868 and in the following year he disposed of it to S. T. Alexander and H. P. Baldwin. The former gentleman was then manager of the Haiku plantation and the acquisition of his interest in the Paia venture necessitated his going to Honolulu to borrow the sum of $9000, which he managed to do, but not without difficulty. Mr. Alexander was the father of irrigation in Hawaii. He promoted and built the Haiku ditch, which was the forerunner of the present magnificent water-distributing system of the islands.

The period from 1869 to 1876 was one of arduous struggle for the planters. Their very existence was at stake. The duty levied on imports by the United States cut their margins down to nothing, labor was scarce and the cost of obtaining it great, the rate of interest was from ten to twelve per cent, agents' commissions for buying and selling ran from five to ten per cent; in short, many plantations were threatened with utter ruin, and so seriously discouraged did the business men become that the only gleam of hope for the salvation of the sugar industry seemed to be annexation.

Repeated efforts were made to negotiate a reciprocity treaty with the United States. Finally this was accomplished; the treaty was consummated in 1876 and a new Hawaii was born.

The expansion that followed was more rapid than the finances of the country could stand. Depression ensued, and as a result the resources of the islands were taxed to the utmost.

The demand for labor during this period of expansion was so great that the pay of the laborers in the fields was raised to one dollar a day, with free rent, fuel and medical attendance. Laborers were sought for in the far corners of the earth, and in consequence the islands have a race mixture rarely found anywhere else in the world.

In 1876 the annual crop of the islands could have been put in one vessel of the capacity of those that are now engaged in freighting Hawaiian raw sugars to the United States, the total being in the neighborhood of 13,000 short tons. At that time, however, this seemed an enormous amount to the planters with their small acreage and mills. It is well known that one planter was very much exercised as to how he was possibly going to handle the extraordinary production of 1100 tons from his plantation, which was then the largest in the islands.

The crop came on the market in such small quantities that it was of no value to refiners, as they could not depend upon definite deliveries. It was therefore put up in special containers, known as “island kegs,” and sold directly to the wholesale grocers on the Pacific coast.

Some plantations turned out sugars that found especial favor with the trade, and these grades brought as high as 14 cents per pound.

Under the benefits of reciprocity the crop increased by leaps and bounds and in a short time the planters ceased selling these raw grocery sugars and turned their attention to supplying the wants of refiners. The “island keg” became a thing of the past and the small sailing vessels which had heretofore carried all the island products to the mainland gave way to steamers. At the present day there is only one sailing vessel plying regularly between San Francisco and the islands, and she usually loads at a port where the large freighting steamers do not care to venture.

Annexation to the United States in 1898 was the next important step in the development of Hawaii. Its immediate effect was to create a feeling of security and confidence in every direction, for while the reciprocity treaty had produced excellent results, the danger of its being made the subject of attack in Congress was ever present. The hoisting of the American flag in the islands permanently dispelled any anxiety on that score.

Of all the early pioneers whose steadfastness and courage kept the sugar industry alive through so many vicissitudes, but few survive. Their descendants have succeeded to their possessions and responsibilities, and today in Hawaii cane cultivation and sugar manufacture have attained a higher degree of development than has been reached by any other country in the world. Crude methods and appliances have long since disappeared. Scientific principles govern the treatment of the land and the selection and care of the cane. The irrigation works are marvels of engineering skill. The mills are modern steel-frame structures, with concrete floors and equipped with machinery of the most improved type. And the end is not yet. The minds of many highly trained men are constantly at work upon the various problems presented by the industry, and what the fruit of their effort will be, who shall say?

Production of Hawaii since 1837 in tons of 2240 pounds:

LOUISIANA

The cane crop of Louisiana comes from the southern part of the state, principally along the banks of the Mississippi, the Bayou Teche and the Bayou Lafourche. As this region is outside the tropics, being between 29 degrees and 31 degrees north latitude, frosts must be looked for in winter. The sugar industry of Louisiana, therefore, as well as that of Texas, Florida and Georgia, has to cope with climatic conditions that are unknown in most other cane-producing countries.

All of the sugar plantations are situated in the low plains, the highest elevation above sea-level not exceeding 83 feet. The annual rainfall varies from 67 to 95 inches, and 80 inches may be taken as a fair average, which amply suffices for the needs of the growing cane. In December, January and February there is always the danger of frost and planters must be constantly alert to guard against this as far as possible. During the autumnal equinox much damage to the cane is caused by hurricanes that rush in from the Gulf of Mexico.

Sugar cane was brought to Louisiana in 1751. According to Gayarré, two ships that were transporting troops from France to Louisiana touched at a port in Hispaniola during the voyage and the Jesuits of the island obtained permission to put some sugar cane on board these vessels to be taken to Louisiana and there delivered to their Jesuit brethren.

The same means were employed to send a number of negroes to cultivate the cane, which was planted according to direction on a piece of ground belonging to the order situated just above the present course of Canal street, New Orleans. The cane grew to maturity and was sold in the market as a luxury.

In 1759 a rich colonist, Dubreuil by name, built a mill and attempted to make sugar, but his efforts were unsuccessful and the idea was abandoned. _Tafia_, a kind of rum, was made from sugar cane shortly afterward.

In 1791 Don António Mendez, an officer of the Spanish crown who lived in St. Bernard parish, bought from a Spanish refugee from Santo Domingo named Solis his land, crop of cane and distilling outfit and attacked the problem with a firm determination to conquer it. He called in a Cuban sugar maker named Morin to assist him, but whether it was that he lacked the means to erect a proper factory, or whether he became discouraged, the fact remains that he only succeeded in turning out a few small barrels of sugar. There is evidence that he did something in the way of refining as well, but not in an appreciable quantity.

The first crop of sugar sufficiently large and profitable to serve as an incentive to others was raised by Etienne de Boré about 1794. Of this achievement Gayarré says: “When the whole agricultural interest of Louisiana was thus prostrated and looking around for the discovery of some means to escape from annihilation, and the eager and anxious inquiry of every planter was ‘What shall I do to pay my debts and support my family?’, the energy of one of the most spirited and respected citizens of Louisiana suddenly saved her from utter ruin and raised her to that state of prosperity which has increased with each successive year.”[42]

In 1794 de Boré purchased seed cane from Mendez and Solis and after planting it he went ahead with his preparations for harvesting, crushing and manufacturing. The following year the sugar he produced sold for $12,000, a considerable sum of money in those days. The boiling of the sugar juice to grain was done under the direction of Antoine Morin, the former associate of Mendez. The method was naturally very primitive, the mill being driven by animal power, and much sugar was lost in the bagasse.

Following the example of de Boré, many planters set out cane and built sugar mills. Their operations were highly successful and they all became wealthy within a comparatively short period.

The industry continued to flourish and prosper, and the year 1820 marked a decided step forward. Up to that time the only two kinds of cane that had been grown in Louisiana were the Creole (from Malabar or Bengal) and the Tahiti. The cane originally planted by de Boré and from which he made his first sugar was the Creole; the Tahiti variety was not introduced from Santo Domingo until 1797. It became patent to the planters that neither of these canes was suited to the Louisianan climate, and they set about looking for a hardier plant. Toward the middle of the eighteenth century the purple and striped varieties were brought by the Dutch from Java to the island of St. Eustatius, and from there a quantity of these canes was taken to Savannah, Georgia, about 1814. They throve extremely well and a former resident of Savannah who had moved to Louisiana and become a planter there, having heard about them, secured some for seed purposes. His experiment proved wonderfully successful and from this single estate the cultivation of the new canes spread over the entire sugar-producing region. As these varieties could stand greater cold than the Creole and the Tahiti, the planters were able to extend their growing area northward and in this way greatly increase their acreage. As recently as 1897 these canes still constituted the crops of Louisiana with a few exceptions.

Of late years, however, seedling canes obtained from Demerara have come into great favor in consequence of the researches of the botanists at the experiment station. In addition to an advantage both in cane and sugar over the varieties previously used, the time of vegetation is shorter, so that the canes mature earlier, and this, on account of the short season in which Louisianan cane has to ripen, makes the Demeraran decidedly desirable. It has also been proved that Demeraran cane is better able to resist damage by storms, so that taking it all in all it would appear that the newer varieties are quite likely to displace the older kinds.

Cane is usually planted in the same ground every three years. The crop of plant cane is followed by a crop of ratoons and then maize is put in. As soon as the maize is cut the field is sown with a species of large pea (_Vigna sinensis_) and when summer is over the pea vines and the maize stubble are ploughed under. A month after this is done, furrows are dug about six feet apart and early in October cane is planted once more. In this operation two rows of whole cane stalks are placed in the furrows and covered with five or six inches of earth as a protection against frost. Most of this layer of earth is removed in the spring to help the growth of the young cane shoots. Stable manure, cotton-seed meal, nitrates, phosphates and kainite are used as fertilizers.

Harvesting begins at the end of November, and, weather permitting, the cane is allowed to remain standing in the fields until required for grinding. If, however, the Government Weather Bureau should predict cold, the cane is cut without delay, piled in the furrows and covered with dry cane leaves to prevent it from freezing. Cane stored in this manner keeps well so long as the weather

remains cold, but as soon as warm weather comes it rapidly deteriorates.

Labor in Louisiana is both scarce and costly, consequently agricultural machinery is used in the fields as far as possible.

[Illustration: HAULING CANE IN THE FIELDS, LOUISIANA]

[Illustration: HAULING CANE IN THE FIELDS, LOUISIANA]

The steam engine was first employed in the crushing of cane in the year 1822. About this time, when slavery was such a tremendous factor in the South, sugar raising was marked by a tendency toward the large plantation method. From 1830 to 1840 the number of plantations in Louisiana decreased, but the number of slaves employed on them increased 40 per cent. Later, however, the plantations began to grow in number and by 1853 there were more than fifteen hundred of them, as against 668 thirteen years previous. In those days, each plantation had its own sugar mill, so that 1853 may be taken as close to the high-water mark for the number of mills in the South. With the outbreak of the Civil war, the industry was virtually wiped out of existence, and when its rehabilitation was begun, it was carried on along entirely different lines and the separation of the raising of sugar from the manufacture was gradually brought about. Year by year the small mills were abandoned and the crops of cane raised by the planters, large and small, were brought to the central factory to be worked up. Today, where large plantations still exist, it is the practice to rent subdivisions of land from twenty to fifty acres in size to tenants who grow cane for the central mill.

In 1880 there were 1144 small sugar mills in Louisiana and their output of sugar was 121,886 tons. In 1911, 187 mills handled a crop of 5,930,000 tons of cane which gave 308,439 tons of sugar, and this would have been considerably exceeded had it not been for a disastrous freeze. In 1880, 273 factories used horse power, in 1900 only 5, in 1905 none at all. The advent of the vacuum pan and the consequent abolition of the open-kettle method marked another great advance in manufacturing development. In 1880 about 42 per cent of the sugar produced in Louisiana was turned out by factories equipped with vacuum pans. The government statistics for 1909 show a total of 316,829 tons of sugar boiled in vacuum pans and only 3,678 tons of open-kettle sugar.

As has been said, the growing season for cane in Louisiana is limited and the harvesting is done before the plant has attained its full maturity. Whether or not this has any effect upon the flavor of the sugar and molasses produced is a moot point. It is none the less true, however, that the Louisiana “Clarifieds” and the so-called New Orleans molasses possess a flavor distinctively their own.

In the plantation fields, too, the scientists have worked wonders. To illustrate the benefit resulting from the application of modern methods to the cultivation of cane, in 1885 the average yield of cane per acre in Louisiana was about three-quarters of a ton, while in 1909 the average yield per acre in cane was about 20 tons, the recovery of sugar per ton of cane over 157 pounds, or 3140 pounds of sugar per acre.

The Louisiana state experiment station was established by the sugar planters at Audubon park, New Orleans, in 1885 and endowed for a term of years. This institution has grown in importance until at the present time it has ample grounds, well-equipped laboratories and a sugar house with an installation of the latest and best sugar-manufacturing machinery, all directed and operated by the students of the institution. Here is carried on the work of developing seedlings, improvement of cane varieties, investigation of cane diseases, together with the study of all questions of bettering plantation and factory methods.

The sugar production of Louisiana in long tons from 1860-61 to the present time is as follows:

1860-61 117,431 1861-62 235,856 1862-63 43,232 1863-64 39,690 1864-65 5,331 1865-66 9,287 1866-67 21,074 1867-68 19,289 1868-69 42,617 1869-70 44,382 1870-71 75,369 1871-72 65,635 1872-73 55,891 1873-74 46,078 1874-75 60,100 1875-76 72,958 1876-77 85,102 1877-78 65,835 1878-79 106,909 1879-80 88,836 1880-81 121,886 1881-82 71,304 1882-83 136,167 1883-84 128,318 1884-85 94,372 1885-86 127,958 1886-87 80,858 1887-88 157,970 1888-89 144,878 1889-90 128,343 1890-91 215,843 1891-92 160,937 1892-93 201,816 1893-94 265,836 1894-95 317,306 1895-96 237,720 1896-97 282,009 1897-98 310,447 1898-99 245,511 1899-00 147,164 1900-01 270,338 1901-02 321,676 1902-03 329,226 1903-04 228,476 1904-05 355,530 1905-06 336,751 1906-07 188,571 1907-08 302,855 1908-09 273,178 1909-10 269,431 1910-11 263,308 1911-12 315,066 1912-13 137,119 1913-14 261,337 1914-15 216,696 1915-16 122,768

PORTO RICO

Porto Rico, the most easterly and the fourth in size of the Greater Antilles, lies at the entrance to the Caribbean sea, between 17 degrees 50 minutes and 18 degrees 30 minutes north latitude and between 65 degrees 30 minutes and 67 degrees 15 minutes

west longitude. It is about 100 miles long by 36 miles wide and has an area of 3606 square miles.

A range of mountains from 2000 feet to 3700 feet in height runs from east to west. The south slope of the island rises abruptly from the foothills, while on the north the ascent is more gradual and broken to a great extent by rugged spurs and deep ravines. There is but little coastal plain on the north, except at the river mouths, but on the south a considerable stretch of lowlands is found. Although many indentations occur in the coast line, few of them afford safe shelter for ships. There are thirty-nine rivers and a great number of smaller streams, but none of the rivers is navigable for more than a mile or two from the sea.

The climate is healthful and is tempered by the northeast trade winds that, with certain modifications due to local conditions, blow steadily the year round. The mean annual temperature is about 80 degrees Fahrenheit. The rainy season begins in May and ends in November and the average yearly precipitation at the foot of Mount El Yunque on the northeast coast is 120 inches. At San Juan it is 55 inches, while other sections of the island are semi-arid or subject to severe droughts. Porto Rico is particularly free from epidemics. The last case of yellow fever was reported in 1897. Cholera and bubonic plague are unknown, and dysentery diseases, formerly common, are steadily decreasing. Like other West Indian islands, it is subject to hurricanes, that of 1899 having been unusually disastrous. The census of 1910 gave the population as 1,118,012.

SUGAR PLANTATION SCENE IN PORTO RICO]

[Illustration: _A. Moscioni, Photo._

SUGAR-SHIPPING PORT, PORTO RICO]

The soil is fertile and may be divided into three classes. First, the red soil, generally found in the mountains; second, the black soil, containing much humus, and third, the coral sand soil of the coast plains. The black has proved to be the best for sugar cane, although excellent yields have been obtained from the coast lands. Notwithstanding the fact that both soil and climate are well suited to cane cultivation, the extension of the industry is checked by the formation of the country. The hilly character of the island and the comparatively limited transportation facilities do not admit of cane being grown in the interior. All of the modern plantations are near the coast, where sugar can be easily transported to steamers. In the north cane may be raised without irrigation, but in the south, where the greater part of the crop is produced, irrigation is necessary. About 400,000 acres of the surface of Porto Rico are under cultivation and half of this area is devoted to sugar. The cane grows chiefly on the rich alluvial lowlands along the coast. On the southern seaboard there is plenty of good land that has never been planted, but to make this available for agriculture means the construction of costly irrigation works with extensive aqueducts and much tunneling.

Porto Rico was discovered by Columbus in 1493. The name Puerto Rico dates from 1521, when gold was found in the island. The natives suffered cruelly at the hands of their conquerors up to the year 1544, when they were set free by the order of King Charles I of Spain.[43] Out of a population originally estimated at 600,000 only a few hundred remained. Great numbers had died and many had fled to Mexico and Peru, but the Spaniards soon filled their places with African negroes.

For three centuries the island was harried by the English, attacked by pirates and freebooters, torn by rebellion among the slaves or terrorized by the fleets of the Dutch, who were intent upon its conquest, so that Spain was kept constantly on her guard to prevent her colony from being wrested from her. This state of affairs naturally did not encourage population. The country could not meet the cost of its administration and the deficit had to be paid out of the revenues of Mexico. Up to 1778 only Spaniards were allowed to settle there, but after that date the privilege was granted to people of other countries, provided they were of the Roman Catholic faith, and in 1815 all restrictions were removed. Foreigners were welcomed to the island and many inducements offered them. Trade with the United States was permitted in 1815, but only in Spanish ships.

This liberal policy brought many planters from the British and French islands, and as they had experience, capital and slaves, they did much to develop the resources of the colony. Subsequently many refugees came from Haiti, Santo Domingo and Venezuela.

Slavery in Spanish possessions was abolished in 1873 and 34,000 slaves in Porto Rico received their freedom.

After Alphonso XII ascended the Spanish throne in 1875, commercial conditions in the island showed a certain improvement, but politically the situation was deplorable, reflecting as it did all the bad features of an obsolete system of government, complicated by a liberalism that was premature. By reason of its arbitrary decrees and many acts of persecution, the administration stirred up a feeling of bitter antagonism on the part of the colonists. A step toward reform was taken in 1877, when the provincial deputation

was re-established, and eighteen years afterward, the home government, in response to vigorous demands from foreign nations, attempted to pass measures to effectively remedy existing evils, but it was far too late. The island received a grant of autonomy in November, 1897, and in July of the following year it was taken over by the United States.

UNLOADING SUGAR CANE AT A MILL, PORTO RICO]

As soon as this became an accomplished fact, there was a marked improvement in conditions, especially from a sugar point of view. Up to this time much attention had been given to the cultivation of coffee, and sugar production had suffered to a certain extent in consequence. Spain had admitted Porto Rican coffee free while protecting it by duties levied on foreign coffee, but when the island passed into the hands of America, this advantage to the coffee raiser disappeared. Besides, the hurricane of 1899 had caused great damage to the coffee plantations and the combination of circumstances proved a severe setback to the coffee industry.

The sugar planters, on the other hand, benefited greatly by annexation. In 1889 the government allowed a reduction of 85 per cent on the duty assessed on Porto Rican sugars entering the United States. In 1901 they came in absolutely free and Porto Rico has enjoyed the full protection of the tariff ever since.

In 1900 Congress passed a law known as the Foraker act, which provided that no corporation should be allowed to acquire more than 500 acres of land in Porto Rico and that no stockholder in any agricultural company operating there should be permitted to hold shares in any other corporation of the kind. The object of the law was, of course, to prevent capitalists from buying up great tracts of land for the cultivation of sugar on a large scale to the detriment of the native land owner.

The act, however, did not serve the interests of the small Porto Rican farmer as its framers apparently intended it should. The owners of large holdings were non-resident and the small farmers lacked the money and enterprise to carry on the industry in a proper manner. The law excluded that which was most urgently needed, namely foreign capital, and when this fact became apparent, the provisions of the measure were construed liberally by the authorities, so that of late years extensive sugar estates have been started in Porto Rico with American, British and French backing, and the production has grown from 85,000 tons in 1902 to 378,509 tons in 1916.

Formerly the Porto Rican planters used to harvest cane from the same lands year after year, without using fertilizers of any kind. When they planted new cane, the soil was only partially prepared; the subsoil was never cleared of roots and rough grasses and cultivation was only indifferently done. The result is that many cane fields are now practically exhausted and some planters find that their lands are becoming spoiled by rapidly multiplying weeds.

Today the usual method is to plough the ground twice before putting in the seed. Deep ploughing is taking the place of scratching the surface and steam ploughs are being used on the larger estates. Where the soil is heavy and the rainfall abundant, the furrows are dug about eight feet apart and two feet deep and the cane planted in double rows at four-foot intervals. In dry, sandy soil the planting is in single rows and the distance between the furrows ranges from four to six feet, according to how rich the soil is. The fields are kept free from weeds and manure is used but seldom.

The greater part of the cane is planted during the last four months of the year and crushing is begun in the second January following, which gives the cane a growing period of fourteen months or more. Some planting is done in January, February and March and this cane is cut in twelve months. Then a certain amount is planted between March and June, and if the sugar content proves satisfactory, it is ground the following season; if not, it is allowed to remain standing for another year. Planting is done every four years and the best results are obtained from the first and second ratoon crops. The yield of cane per acre averages about 18 long tons, although this has been exceeded in good years. The cane is cut close to the ground with a _machete_ and loaded on ox-carts to be taken to the mill or the railway station, according to the location of the field.

Almost all of the cane grown in Porto Rico is ground in the large central factories, but it is only during the last ten or twelve years that this has been done. The small mills have disappeared for the most part, although a few have been able to struggle along.

The centrals usually raise about one-half of the cane they grind. The rest they buy from the _colono_, who grows cane either on his own land or upon ground rented to him by the central owner. As a rule the price paid to the _colono_ for his cane is 5 per cent of the weight of the cane in sugar, although this is subject to modification at times. As the central factories are of recent construction, they are equipped with the newest and best machinery and the most scientific methods govern their operation.

In 1853 Porto Rico exported 112,000 tons of sugar; the following year the amount was 70,000 tons and during the next twenty years it remained nearly stationary. In 1871 the production reached 105,000 tons, dropping back to 89,000 tons in 1885 and 65,000 tons in 1886. The crop of 1900 was very small—35,000 tons—owing to the havoc wrought by an unusually severe hurricane, but from that time on it has increased year by year.

As most of the diseases and pests that attack sugar cane are met with in Porto Rico, it is obvious that the work of the United States agricultural station at Mayaquez has been of inestimable benefit to the planters. Experimenting with different varieties of cane, importing seed cane from other countries, analysis of soils, scientific advice upon the use of fertilizers and instruction as to the best means to destroy or control harmful parasites, these are but a few of the many important services rendered by the station.

The outlook for Porto Rico's sugar industry seems hopeful. Labor is cheap and abundant, climatic and soil conditions are favorable and an irrigation project at present under way promises to convert lands now arid into productive cane fields.

Since 1900 the production of sugar in Porto Rico in tons of 2240 pounds has been:

1900 35,000 1901 80,000 1902 85,000 1903 85,000 1904 130,000 1905 145,000 1906 213,000 1907 210,000 1908 200,000 1909 245,000 1910 308,000 1911 295,000 1912 320,000 1913 350,323 1914 325,000 1915 308,178 1916 378,509

THE PHILIPPINES

This group of islands is situated about 500 miles off the southeast coast of Asia, between 4 degrees 10 minutes and 21 degrees 10 minutes north latitude and between 116 degrees 40 minutes and 126 degrees 34 minutes east longitude. It is bounded on the west and north by the China sea, on the east by the Pacific ocean and on the south by the Celebes sea. It comprises 3141 islands, of which 2775 contain less than one square mile each. According to the Philippine census of 1903 the total area is 115,026 square miles,[44] although some authorities estimate it to be as much as 127,800 square miles. Two-thirds of this is forest land and not more than 9½ per cent of the entire archipelago was classified under _Farms_ in 1903. The area devoted to sugar cane the year previous was 177,628 acres, about 5 per cent of the cultivated land.

The islands are chiefly of volcanic origin and their surface is much broken by hills, isolated volcanoes and mountain ranges running north and south, northwest and southeast or northeast and southwest. There are twelve active volcanoes in the group and eight others with well-defined cones that are either dormant or extinct. The highest elevation in the islands is Mount Apo, an extinct volcano on Mindanao, 10,312 feet, with Mount Mayon, an active volcano on Luzon, next, 8970 feet. Earthquakes are frequent and occasionally violent.

The most important of the group are Mindanao, Luzon, Samar, Palawan, Panay, Negros, Leyte, Mindoro, Cebú, Masbate and Bohol. The coast line, which is over 11,000 miles in length, is fringed with coral reefs and indented by many gulfs and bays. There are plenty of good natural harbors, the principal one being Manila in Luzon, which affords perfect shelter for shipping, even in the severest storms. Next in importance are the harbors of Iloilo and Cebú.

Climatic conditions vary widely. However, it may be said in a general way that the climate is characterized by a uniformly high temperature, excessive humidity, heavy rainfall and violent tropical storms. Near the seacoast, it is moderate between November and the first of March. The latter part of March and the months of July, August and September are warm and very hot weather comes in April, May and June. The nights, however, are always cool. The temperature naturally changes as the elevation above the sea increases, but at ordinary levels it averages 77 degrees Fahrenheit in January, and 83 degrees in May.

The annual rainfall is about 74 inches, and two-thirds of this comes in July, August, September and October. Of course the precipitation in certain localities is affected by mountain ranges that cause condensation from moisture-laden trade winds. In the lowlands that are not protected by mountains, the rainfall is regular. Typhoons occur between April and October, but they are not nearly so severe as the hurricanes that visit the West Indies and Mauritius. In October, 1882, a typhoon did a great deal of damage in Manila, and there was a serious loss of life in the great storm that visited Samar and Leyte in 1897. The well-appointed observatory in Manila sends out warnings of the approach of typhoons and much life and property are saved by this means.

The soil is generally reddish-brown in color and is largely made up of disintegrated lava with an admixture of decayed vegetable matter; sometimes decomposed coral limestone is present.

John W. Dwinelle, in an address delivered in San Francisco in 1866, said: “Previous to the discovery of America by Columbus in 1492, the Portuguese had discovered the Azore islands in longitude 31 W., and on the strength of that discovery claimed that the countries discovered by Columbus belonged to the crown of Portugal, and that the Spaniards should be wholly excluded from them. But the Spaniards refused to admit this pretension and referred the matter for decision to the Pope, Alexander VI. It was then part of the law of nations, and of the public law of the world, that the Pope was the ultimate source of all temporal power; that he could make and unmake kings, and dispose of all the kingdoms of the earth—powers which he frequently exercised and against which it were vain to contend. He was therefore, by general consent, the acknowledged source of all lawful title to land. He assumed to decide the case thus referred to his decision, and on May 3d, A. D. 1493, determined the matter in dispute between the crowns of Portugal and Spain, by drawing an imaginary line of longitude one hundred leagues west of the Azores, and granting to the Spanish monarchs all countries inhabited by infidels, which they had already discovered, or might afterwards discover, lying to the west, and to the crown of Portugal all those lying to the east of that line. This line was afterwards removed two hundred and seventy leagues further to the west, by a treaty subsequently made in the year 1494, between the kings of Portugal and Spain; but so thoroughly was the title thus conceded by the Pope respected by the civilized world, that when Henry VII of England was afterwards about to intrude upon some of the dominions thus granted to Spain, he abandoned his project upon being warned by the Pope to desist.”

This division of the surface of the globe into two parts gave to Portugal all the territory both known and unknown east of the arbitrary meridian drawn 470 miles west of the Cape Verde islands, and to Spain everything west of this line.

Ferdinand Magellan, the famous Portuguese navigator, in the service of the Emperor Charles V of Spain, set out on a voyage west-bound with the object of taking possession of the Moluccas, as they lay west of the line of demarcation. Sailing around Cape Horn, Magellan discovered the Philippine islands in 1521, landing first on Malhou, between Samar and Dinagat. Afterward, he touched at Mindanao, from which he sailed to Cebú. Thence he went to the small island of Mactan, where he was killed in a skirmish.

But little action was taken with regard to this territory until after the accession of Philip II (hence “las Filipinas”—Philippines), when an important expedition was fitted out at the Mexican port of Navidad. It sailed in November, 1564, under the command of Miguél Lopez de Legaspi, the distinguished conquistador, who, in the following year established on the island of Cebú the first permanent settlement in the Philippines. The city of Manila was founded in 1571 and became the capital of the group. Through his tact, courage and resourcefulness, Legaspi won the confidence of the people and placed the colony on a sound footing. At the same time he checked all attempts at encroachment on the part of the Portuguese. Spanish rule was undisturbed until 1762, when a British naval force bombarded Manila and occupied it. At the conclusion of the war between Great Britain and Spain in 1764, the British withdrew and the domination of Spain endured until 1898, when the Spanish fleet was destroyed by Dewey at Manila bay.

The title to the Philippines therefore passed through the Pope to Spain and from Spain to the United States.

When Magellan reached these islands he found that sugar was made in a primitive fashion. The methods employed were very much like those in vogue in China, and the sugar, when made, greatly resembled the Chinese product. This is very strong presumptive evidence that cane and the knowledge of its manufacture were originally brought to the Philippines by the Chinese.

[Illustration: HAULING CANE, PHILIPPINES]

[Illustration: CARABAO MILL, PHILIPPINES]

The industry, however, amounted to very little prior to 1849, in which year the island of Negros was placed under the jurisdiction of the religious order of Recoletos, who did much to encourage the manufacture of sugar, and this movement was stimulated by the high prices resulting from the Crimean war. In consequence, cane sugar was exported with profit from Negros, Luzon and Cebú. Notwithstanding the lack of capital, the rough, crude mills, the planters’ scant knowledge of manufacturing methods and the wretched transportation facilities, the sugar trade forged rapidly ahead until in 1893 the exports totaled 257,550 long tons. A slump in the price of silver, however, brought on a financial crisis, and subsequently internal dissensions affected the crops so that in 1901

only 51,448 tons were exported. Since then a change for the better has taken place and the figures for 1915-16 indicate a production of 345,000 tons.

Sugar cane is used as a delicacy in all of the inhabited islands of the Philippine group, but the growing and manufacture of it as a regular industry are confined to Negros, Mindoro, Cebú, Panay, Luzon and Leyte. In 1914-15 about 350,000 acres altogether were planted in cane, and the quantity of sugar exported during 1916 was about 300,000 tons.

The first care of the United States after its occupancy of the Philippines was the bettering of conditions in sanitation, education, banking methods, railway communication and deep water terminals. Apart from the primitive character of the sugar mills and the loss growing out of poor extraction of juice, open-kettle boiling and curing in earthen pots, the sugar producer was generally in debt to the buyer for advances that carried a high rate of interest. The government has taken steps to correct this evil and has made it possible for the farmer to get credit on reasonable terms, limiting its loans, however, to those who have Torrens titles to their property,[45] but the Filipino has been under the influence of the money-lenders too long for him to break his bonds entirely. Besides, his instinctive dislike for anything new is a hindrance to progress in this direction.

In addition to the measures just alluded to, a special law was passed in 1902, under which all Philippine sugars entering the United States paid 25 per cent less than the regular customs tariff. The Payne-Aldrich bill of August 5, 1909, provided for free admission of Philippine sugars up to 300,000 gross tons, and it stipulated that the small producer (less than 500 tons per annum) was to receive first consideration in the event of the importation exceeding 300,000 tons. Any excess coming into the United States would have been assessed the full tariff. During the life of this legislation, however, the largest production of the islands was that of 1913-14, which amounted to 265,000 tons, of which 225,000 tons were exported.[46] The tariff act of 1913, which became effective March 1, 1914, admits all Philippine sugars free of duty without any restriction as to quantity.

The religious orders were formerly large land owners in the Philippines, and the feeling of discontent that ultimately led to the insurrection of the Filipinos against Spain in 1896 was largely due to agrarian difficulties between the friars and their tenants. When the revolution came, the friars had to flee for their lives, and after peace was restored by the United States, the insular government felt that if they returned to their possessions they would be in constant danger from the hostility of the natives. It was, therefore, decided to acquire these lands and to that end Congress passed an act authorizing the Philippine government to issue bonds to the amount of $7,000,000 and to purchase the lands of the various orders with the money so raised. With one or two minor exceptions, all of these lands, amounting to something over 600,000 acres, were bought by the government and are being resold on long-term payments at a price that will reimburse the government. In disposing of this property preference is always given to the resident tenants.

[Illustration: OLD-STYLE SUGAR MILL, PHILIPPINES—SHOWING POOR CRUSHING]

[Illustration: TINGUIAN CANE CRUSHER, LINGAYEN, PHILIPPINES]

A measure was carried through the Philippine legislature approving the sale of the unoccupied portions of these friar estates to individuals without restriction as to acreage, and it was under the provisions of this act that large tracts of land were acquired by the interests connected with the Mindoro company in the San José estate in Mindoro and by the people associated with the Calamba estate in the Calamba, Santa Rosa and Biñan districts of Laguna province, Luzon.

Apart from these so-called friar lands, the public lands in the Philippine islands are held for sale or lease subject to the following conditions: Corporations can purchase or lease up to 1024 hectares, or 2500 acres, and individuals up to 64 hectares, or 158 acres. The terms of sale are a minimum of 10 pesos, or $5 per hectare, 25 per cent of which must be paid at the time the contract is entered into and the remainder within five years, with interest at 6 per cent, or leased at a minimum rental of 50 centavos, or 25 cents, per hectare per annum, leases running for fifty years.

The Mindoro and Calamba companies, controlling 55,000 and 20,000 acres respectively, and the San Cárlos Milling company of San Cárlos, Negros, have erected the first and only modern sugar mills in the Philippines, and they have gone into cane cultivation and sugar manufacture in a scientific way. The management of these three enterprises has been entrusted to men who have had thorough field and factory experience in Hawaii.

Unlike the other two large companies, the San Cárlos Milling company operates a _central_ pure and simple. The company owns no land except the site for the mill and the outbuildings connected with it. It has, however, acquired leases of a certain amount of railway trackage. The capacity of the mill is 1000 tons of cane per day, which means about 125 tons of centrifugal sugar. It was

completed at the end of 1913 at a cost of about one million dollars, and the first cane ground was from the 1914 crop.

In the Philippines cane is not planted every year. Herbert S. Walker, in his work “The Sugar Industry in the Island of Negros” (Manila, 1910), says: “A decidedly large proportion of the total land under cultivation in Negros is not replanted every year, but is allowed to ratoon, from two to eight crops being taken off without replanting. This is especially true in the rich soils of the districts around Ilog-Cabancalan, Binalbagan-Isabela, San Cárlos and Bais. Theoretically, cane planted in some of these alluvial soils, which are flooded and fertilized each year by silt brought down from the mountains by the overflow of a river, might go on ratooning indefinitely. Practically, the period between plantings is limited strictly by financial considerations.

“Much time and expense are saved by not being obliged to replant. On the other hand, the yield from plant cane is, as a rule, greater than even from first ratoons, and with each successive ratoon crop the total amount of sugar produced per hectare of land is decidedly diminished. This is partially due to the shorter time in which the cane is allowed to ripen. Owing to excessive rains prevalent in this country, canes must be cut every year, and the practice so common in Hawaii of allowing ratoons to ripen for eighteen months or more, is here out of the question. A further obstacle, especially when canes are planted closely in rows, is the tendency of ratoons to spread out in every direction from the original plant so that in the course of a few years the cane rows lose all semblance of regularity, and proper tillage of the soil is rendered very difficult; thus many young ratoons are stunted in their growth by weeds.”

[Illustration: OLD WATER-DRIVEN MILL, ISLAND OF NEGROS, PHILIPPINES]

[Illustration: MILL DRIVEN BY WATER POWER, OCCIDENTAL NEGROS, PHILIPPINES]

The time of planting in most parts of the islands is usually from December until April, but in Negros, where the soil is good and the rainfall well distributed, planting can be done at almost any time, except during the period of very heavy rains, _i. e._, from July to October.

The yield of sugar per acre may be approximated as follows:

Plant cane 2.5 tons First ratoons 2.0 ” Second ratoons 1.75 ” Third ratoons 1.50 ” Fourth ratoons 1.25 ”

When the yield drops as low as eight-tenths of a ton of sugar per acre, replanting is necessary, and allowing for the reduced yield of first and second ratoons, it may be reckoned that one-half of the production is from plant cane and the other half from ratoon crops.

The length of time during which the cane is allowed to remain in the ground varies from nine to fourteen months and will probably average between eleven and twelve.[47]

The labor problem is present in the Philippines as in all cane-sugar countries. The natives are willing enough to work, but shrink at the idea of leaving their homes to take employment at any considerable distance away.

Apart from the three modern factories previously mentioned, sugar-making facilities are greatly behind the times, although there are a few minor exceptions. Over one thousand small mills were in operation in the islands in 1907 and of these 528 were driven by steam, 470 by carabao (water oxen) or natives, and 77 by water power. The carabao mills, however, are rapidly disappearing. The capacity of most of these small mills is from 50 to 60 tons of cane per day, and, as the cane is only crushed once, there is a considerable loss in recovery. A little lime is added to the juice to clarify it and it is then boiled to grain in a series of five or six open pans. The general arrangement is shown by the accompanying sketch, which is taken from Herbert S. Walker’s “Sugar Industry in the Island of Negros.”

[Illustration]

The drawing shows two sets of pans, each set being built over a separate furnace. The number 5 pan, into which the juice from the crusher flows, is connected to both sets. The furnaces are fed directly under number 1 pan, where the final boiling is done and where the greatest heat is required. The two furnaces converge when they reach the boiler, which may be fired separately, so that grinding and boiling may, if necessary, be done independently of each other. As the juice leaves the crusher through an open wooden trough, particles of cane and other matter are removed by straining through a cloth or a close-meshed wire screen. It runs into the receiving pan—number 5—and is heated to between 160 and 175 degrees Fahrenheit, which brings certain impurities to the surface in the form of froth. This is skimmed off and thrown into the scum tank; the juice is then ladled by hand as required into the smaller pans (number 4) where lime is added for clarification. Violent agitation takes place in pans numbers 3 and 2, and as fast

as scum forms it is skimmed off. The clarified juices are then concentrated in pans number 2 and number 1, after which the massecuite is put into wooden trays and stirred with a spade until it granulates. It is then ready to be taken to market.

[Illustration: NATIVE SUGAR FACTORY, PAMPANGA PROVINCE, PHILIPPINES]

[Illustration: INTERIOR OF CAMARIN, PHILIPPINES]

As has been pointed out, the loss in this primitive method of manufacture is very heavy. Notwithstanding the fact that all of the molasses is retained in the sugar, the amount of sucrose that is lost or wasted is 44 per cent, and over one-half of this is left in the bagasse.

Apart from centrifugals, Philippine sugars consist of the following grades: _Superior_, _Humedo_ (wet) and _Corriente_ (current). Sugars polarizing from 87 to 88.9 degrees are called Superior No. 1, those testing from 85 to 86.9 degrees, Superior No. 2, and those running from 80 to 84.9 degrees, Superior No. 3. Humedo sugars polarize from 76 to 79.9 degrees and Corriente from 70 to 75.9 degrees. Roughly speaking, the proportions are about 85 per cent of Superior of 84 degrees purity and 15 per cent of wet sugar testing somewhere near 75 degrees.

The Bureau of Agriculture of the Philippines maintains experiment stations at La Granja, near La Carlota, Occidental Negros, and at Calamba, Luzon, for the study of cane, soil analysis and the solving of fertilization problems. This work of scientific investigation is sure to be of great benefit to the industry. Some experimental work with sugar cane is also carried on at the station at Alabang, Laguna province, Luzon.

American control in the Philippines promises much for the future of the sugar industry of these islands, for when it is remembered that for many years, in spite of the handicap of crude, uneconomic methods, export duties at home and import duties abroad, sugar was made and sold at a profit in the markets of the world, it is not unreasonable to look for a considerable stimulus to be given to production by advanced scientific management and free admission of the commodity to the markets of the United States.

Quantity of sugar exported from the Philippine islands from 1895 to 1916, in tons of 2240 pounds:

1895 227,279 1896 226,279 1897 198,899 1898 177,962 1899 91,583 1900 61,752 1901 51,448 1902 90,617 1903 88,144 1904 82,656 1905 103,334 1906 122,417 1907 120,050 1908 140,197 1909 125,276 1910 114,506 1911 203,394 1912 190,702 1913 155,201 1914 232,761 1915 207,679 1916 300,000

CUBA

The island of Cuba lies between 74 degrees and 85 degrees west longitude and 19 degrees 40 minutes and 23 degrees 33 minutes north latitude; its length is about 730 miles, running nearly east and west, and its width varies from 25 to 100 miles. In area it comprises about 45,883 square miles, or 29,365,120 acres, which is approximately that of Pennsylvania or Louisiana. Habana, the capital, is almost on the same parallel as Honolulu and the City of Mexico.

With the exception of a strip of the central-southern coast, Cuba rises boldly out of the sea and presents a rugged appearance to the eye on approach. About one-quarter of its surface is mountainous; three-fifths consists of gently sloping country, valleys and rolling plains; the rest is swampy.

A variety of topographic and climatic characteristics divides the island naturally into three distinct parts. The eastern end is high and broken, with tall commanding peaks; the wide central region, lying well above sea-level, is made up of excellently drained, undulating plains, interrupted at intervals by low, wooded hills; the western portion is a picturesque country of mountain and valley, but of lower altitude than the eastern end. The entire island is covered with a mantle of luxuriant verdure, kept always green by warm mists and generous rains.

A coral reef extends around the greater part of the coast, but between the forbidding rocks and the marshes there are a number of good harbors, chiefest among which is that of Habana, one of the finest in the world. The distance from Cuba to Key West, Florida, is one hundred miles. The census of 1908 placed the population at 2,048,890.

The prevailing winds are the northeast trades, but these are interrupted at frequent intervals by variable winds from other directions which bring changes in temperature and rainfall. Compared with those of Hawaii, the mountains are low, usually not over 2000 feet, and do not produce the effect of a wet side and a dry side to the island, as the trades sweep it from end to end and not transversely. To give an idea of climatic conditions, the average maximum temperature in Habana in 1914 was 90 degrees Fahrenheit, the minimum 53 degrees and the mean average 77 degrees. The total rainfall was 46.15 inches. Seventy-five per cent of the rain occurs in the summer months, between the first of May and the first of October, and the precipitation is greater in the eastern part of the island than in the western. The winters are comparatively dry. This combination of dry winters and wet summers is extremely favorable to the growing and harvesting of sugar cane.

The low plains along the coast are of coral formation and the soil overlying the coral is often found to be shallow. The richest and most productive soil is that of the uplands some distance from the sea. In Cuba the soils may be said to consist of two kinds—the red and the black. The red is generally of great depth, from 30 to 50 feet, and rests on a stratum of free limestone. The black soil, varying in color from a mulatto to a “gumbo” black, overlies a clay formation, and as a general rule is not so deep as the red soil. Owing to the fact that the black soil retains such a large percentage of water during the extremely rainy period, the cost of cultivation is double that of working the red soil.

CENTRAL FACTORY, GENERAL VIEW, CUBA]

[Illustration: _American Photo Co., Habana._

CUBAN CENTRAL—GENERAL VIEW]

The date of the introduction of sugar into Cuba is uncertain. Different authorities place it anywhere from shortly after the discovery of the island in 1492 to 1580. Von Humboldt is silent on the point, but says that Cuba did not participate in the sugar industry to any extent in the sixteenth century, so that its importance in that respect belongs to a later period.[48] Up to 1772 sugar cultivation was greatly hampered by restrictions of the Spanish government; after that date special privileges were canceled and the right to grow sugar was given to all Spaniards. This naturally encouraged production, which from 4390 tons in 1760 increased to 14,000 tons in 1790. The revolution which destroyed the sugar plantations and mills of Santo Domingo in 1791 stimulated the development in Cuba still further. During the ten years that followed, the number of mills increased from 473 to 870, and by 1802 the output of sugar reached 40,800 tons. In those days mills were very small, crude affairs and were worked by oxen.

Cuba, in common with all sugar-raising countries, felt the effects of the European wars very severely, but her sugar trade revived after the overthrow of Napoleon and the resumption of commerce through normal channels.

With increased production the question of labor became a serious one. The number of slaves on the island had been sufficient as long as the sugar crop was limited, but with expansion came the need for more African negroes, so in 1834 the governor, Miguél Tacon, caused many new slaves to be brought in. He did much to help the industry in other directions, particularly by suppressing abuses, and under his administration the planters enjoyed prosperity such as had never been known. Fresh lands were brought under cultivation and the shipping ports grew in importance and activity.

While figures showing the annual production of Cuba were tabulated, beginning with 1850, their accuracy was open to question until 1882, in which year an export duty was imposed, and the records kept by the authorities from that time forward are reasonably correct. Nevertheless, it is known beyond any doubt that 610,000 tons were produced in 1870 from 1200 small mills.

The first war with Spain (1868-78) and the abolition of slavery worked havoc with the industry. All children born of slaves were proclaimed free in 1872 and slavery was entirely abolished in 1880, without any indemnification to the slave owners. Sugar producers found freeman labor both costly and hard to obtain, the island was ravaged by fire and sword, and in the markets of the world beet-root sugar, protected by bounties, was proving a powerful competitor. These were dark days for the planter.

With the restoration of peace, conditions improved. By 1890, 470 mills were in operation and their production in that year was 625,000 tons. In Cuba a change in methods came about, just as had been the case in Louisiana; the cultivation of sugar was gradually dissociated from its manufacture, and as mills became fewer in number, plantings increased. The manufacturers leased tracts of land to farmers, from whom they bought the cane raised on it. Independent planters, too, sold their cane to the central mills, and the plan was adopted so generally throughout the island that but little cane was grown by the owners of the centrals.

During this period of peace and development, the tonnage mounted steadily upward and in 1894 it totaled 1,054,214 tons.

LOADING CANE ON OX-CARTS, CUBA]

The following year saw the renewal of hostilities with Spain, which dragged along with brutality and devastation until May, 1898, when the United States declared war against Spain and finally established the Cuban republic. The period of this second rebellion against Spain was marked by ruthless destruction of property, the burning of mills and cane in the fields, and the killing of the cattle that were used for transport purposes. In 1897 the output of sugar had shrunk to 212,051 tons. The work of reconstruction after the expulsion of the Spaniards was slow, involving as it did a tremendous amount of effort and the investment of a great deal of new capital. Manufacturers who were unable to raise money to rebuild or re-equip their mills turned planters and grew cane for the nearest centrals. Some, more fortunate, succeeded in securing the money they needed and restored and extended their property. Far the greatest number, however, being unable to command the ready cash for immediately necessary repairs, incorporated or sold their holdings outright to newcomers. The many small, old-fashioned mills have given way to a limited number of large plants, or centrals, that are under corporate ownership and governed by scientific business principles. This process of consolidating several small factories into one big one is constantly going on, and in addition American capital and enterprise are opening up new lands to cultivation in many parts of the island. To a great extent the old-time planter has had to make room for the corporation, with its powerful resources and modern methods, and while the individual has suffered in many instances, the industry has greatly benefited.

Cuban plantations may be divided into two classes, the ingenios and the centrals. The ingenio is a small plantation whose lands lie in the neighborhood of the mill, while the central, in addition to its own cane, handles the crops of a number of ingenios. The ingenio hauls all of its cane to the factory by ox-carts; the central is served by railroads, both privately and publicly owned, and its equipment and machinery are of the most modern type.

Approximately 90 per cent of the cane grown in Cuba comes from what are termed _colonias_, _i. e._, farms varying in size from a few acres up to several hundred.

Colonos, or farmers, may be classified in three groups: in the first is the man with his small _estancia_, or farm, on which he raises foodstuffs and cattle, and who takes his few hundred _arrobas_[49] of cane to the central when the price is good, or feeds it to his animals when the pasturage is short. In this class, too, is the man who has a hundred or two hundred _caballerías_[50] of land, but whose chief interests are in other channels and whose operations in cane growing are merely an adjunct to his regular business.

In the second group is the independent farmer, who owns his land and cane and sells his crop to whom he pleases.

The third and most numerous group comprises those who plant cane on lands belonging to the central. These people either pay rent, or receive a certain fixed amount for their cane, or both. Their work is at all times subject to inspection by the central administration and under such circumstances they may be likened to contractors or employés, whose compensation is based upon the success of their own efforts.

The average size of a colonia, exclusive of those owned by colonos of the first-mentioned class, who are independent of cane growing, doubtless depends upon what would afford a man a decent living with a few luxuries. H. C. Prinsen Geerligs, in his book “The World’s Cane Sugar Industry,” states that one hundred arrobas (2500 pounds) of cane costs the Cuban farmer $2.07 at the mill. If 2½ cents be taken as an average price for sugar and $900 per annum as a fair living wage, then the colono who gets an average yield of 50,000 arrobas per caballería and is paid for it at the rate of 5 per cent, receives $1560 per caballería for cane that has cost him $1035 to produce. According to this reasoning, a colonia should not be less than 1.75 caballerías in size, but of course this is purely speculative.

The farmer who owns his land is paid about six per cent[51] of the weight of the cane he furnishes in centrifugal sugar of 96 degrees, sacked and ready for shipment, and occasionally delivered at the nearest shipping port. Sometimes settlement is made in cash, based upon the value of the agreed percentage of sugar at the Habana quotation on the day the cane is delivered. In other

words, for every one hundred pounds of clean cane in bundles, delivered on board the cars, the plantation pays the grower about six per cent of 96-degree centrifugal sugar, or its equivalent in money.[52]

Where the land is furnished by the plantation, the farmer is paid from four to five per cent of the weight of the cane in sugar. He is given a house free of rent and an acre or two of garden land as well. All material, labor or stores supplied to him are debited to him to be accounted for when final settlement is effected.

Planting cane in Cuba is a simple matter. In preparing virgin forest land for seed, no ploughing whatever is done; the trees and shrubs are cut down and allowed to dry, the valuable timber is carried away, and the remainder is burned. When this is done the land is found to be smooth and level, as a rule. Planting consists in making holes in the ground with a heavy pole shod with iron that is driven obliquely into the earth at regular intervals, the seed is then dropped in these holes and covered with earth, completing the operation. Grassy ground, however, must be ploughed, in which case furrows are made six feet apart. The seed cane is planted in them at intervals of from six inches to twelve inches, covered with earth and left to grow. There are the spring plantings and the autumn plantings, the first from April to June and the second in October and November, that is to say, one at the beginning and one at the end of the rainy season. In the case of the former, if the rains come soon after planting, the cane can be cut in the following March or April, _i. e._, after a growing period from nine to twelve months. If, however, the rains are late the cane cannot mature before the advent of the new rains and therefore cannot be ground until the following December. Cane planted in the fall ripens in December of the next year or sometimes a month later.[53]

Notwithstanding the little care given to the planting, the cane once started yields a generous crop, which is followed by profitable ratoon crops for a number of years without fertilization or a great amount of tillage. Finally, when through age the cane ceases to produce a paying crop of ratoons, the old roots are taken up,[54] and the same soil reseeded brings forth excellent results for another period of years without any rotation of crops being necessary. Not more than ten per cent[55] of the total area of Cuba is devoted to the growing of cane. In addition to the ground on which cane is actually planted, large tracts are needed as pasture for draft cattle. Besides, there is much forest land and many barren spaces that are undoubtedly included in the acreage classified as being under cane cultivation. According to Dr. W. D. Horne,[56] the average yield is from fifteen to twenty tons of cane per acre[57] and the crops are usually allowed to ratoon for ten years.

SELF-DUMPING CANE CAR, CUBA]

In Cuba, cane diseases are of rare occurrence, but in dry years swarms of mice invade the fields and cause great damage by gnawing the cane. They rapidly disappear, however, as soon as the wet season sets in. It is the weather that brings success or failure to the sugar crop, for the growth of the cane is entirely dependent upon rainfall and a long period of drought is extremely hurtful. Hurricanes that sweep in from the Caribbean sea work havoc in the plantations, beating the cane flat to the ground or uprooting it altogether, which results in heavy damage both to the growing crop and the one following it.

Harvesting is generally begun in December and over in May, although one or two centrals continue in operation practically all the year round. Weather conditions determine when the grinding starts and ends, for, as a rule, the cane has to be hauled from the fields to the weighing station in huge carts drawn by oxen. When the roads are dry, three pairs of oxen can pull a load of 7500 pounds of cane with ease, but as soon as the heavy rains set in the ground quickly softens, the roads become impassable and the movement of cane by carts is out of the question.

The cane is cut close to the ground with a long, heavy knife, called a _machete_. It is “topped,” cut into two- or three-foot lengths, tied in bundles and loaded on the ox carts to be hauled to the scales and thence by rail to the mill. The stumps that remain in the ground are covered over with dry leaves to conserve the moisture in them. Nourished by occasional showers, the roots quickly sprout and a year afterward a crop of ratoons is ripe and ready to be harvested.

Wages in Cuba are higher than in most important cane-producing countries in the tropics, and Dr. V. S. Clark quotes a number of authorities to show that inefficiency makes Cuban labor costs in most lines of work relatively higher than in the United States and other countries on the American continent, although he says that American supervision has in some instances increased efficiency

greatly.[58] (Bureau of Labor, Bull. [L. of C.] 41, pp. 712, 778.)

Complete, reliable and up-to-date information and statistics concerning Cuba's sugar industry are not obtainable at the moment, nevertheless it is well known that the Cuban plantations and mills that are operated by modern scientific methods can produce sugar at lower costs than Germany or any of the beet-raising countries, while as regards cane-growing countries, Java is the only possible rival. And yet, despite the optimistic views of Cuba's supporters, the fact remains that the full development of her resources is still a matter of uncertainty, though the possibilities for expansion are enormous, provided that certain obstacles, notably the labor problem, can be overcome. At the present time it is doubtful whether the production of sugar could be largely increased, chiefly because of the growing difficulty of securing adequate help in the fields.

During the season ending midsummer, 1915, Cuba's output of sugar was 2,592,667 long tons, the largest crop raised in any country in the world, and the vast amount of cane from which it was manufactured was ground by 176 central factories. It is estimated that the production for 1916 will reach 3,000,000 tons.

When it comes to the marketing of her sugar the United States is Cuba's best customer, only a comparatively small amount being taken by Europe.[59] The 20-per-cent preferential allowed on Cuban sugar duty under the reciprocity treaty, however, does not always go to the Cuban manufacturer. The real beneficiary is the consumer in the United States, for this reason: when the grinding of the Cuban crop is in full swing, the weekly production of raw sugar is approximately 150,000 tons, which speedily exhausts the available storage capacity of the island, so that movement of the sugar is imperative; besides this, the natural anxiety of the planter to realize in order to meet his current expenses causes a strong pressure to sell. It becomes with him a question of whether he can net better figures in New York or the United Kingdom, and owing to difference in port charges and dispatch, the New York results are generally more satisfactory, even with the concession of a part, or at times all of, or even more than, the 20-per-cent preferential. Inversely, it follows that when raw sugars are in keen demand, the planter pursues his advantage to the limit.

The total production of sugar in Cuba from 1850 to the present year is as follows, but the figures prior to 1882 are not entirely dependable, as has been previously explained:

YEAR TONS

1850 223,145 1851 263,999 1852 251,609 1853 322,000 1854 374,000 1855 392,000 1856 348,000 1857 355,000 1858 385,000 1859 536,000 1860 447,000 1861 446,000 1862 525,000 1863 507,000 1864 575,000 1865 620,000 1866 612,000 1867 597,000 1868 749,000[60] 1869 726,000[60] 1870 726,000[60] 1871 547,000[61] 1872 690,000[60] 1873 775,000[60] 1874 681,000[60] 1875 718,000[60] 1876 590,000[60] 1877 520,000[60] 1878 533,000[60] 1879 670,000 1880 530,000 1881 493,000 1882 595,000 1883 460,327[62] 1884 558,932 1885 631,000 1886 731,723 1887 646,578 1888 656,719 1889 560,333 1890 632,368 1891 816,980 1892 976,000 1893 815,894 1894 1,054,214 1895 1,004,264 1896 225,221[63] 1897 212,051[63] 1898 305,543[63] 1899 335,668 1900 283,651[64] 1901 612,775 1902 863,792 1903 1,003,873 1904 1,052,273 1905 1,183,347 1906 1,229,736 1907 1,444,310[65] 1908 969,275[66] 1909 1,521,818 1910 1,804,349 1911 1,483,451 1912 1,895,984 1913 2,428,537 1914 2,597,732 1915 2,592,667 1916 3,000,000[67]

JAMAICA

Jamaica lies 80 miles south of the eastern end of Cuba, between 17 degrees 43 minutes and 18 degrees 32 minutes north latitude and 76 degrees 10 minutes and 78 degrees 20 minutes west longitude. It is 144 miles long and 50 miles across at its widest part, with a total area of 4207 square miles.

The island is traversed from east to west by a mountain range from which a number of spurs run out to the northwest or southeast. This range is more sharply defined in the eastern end, where the highest point is Blue Mountain Peak, 7360 feet above sea-level. The mountains gradually slope westward down to the hills of the western plateau, which is of limestone formation and comprises two-thirds of the island's surface. As a rule the highlands terminate abruptly in steep bluffs, a strip of level land lying between them and the sea. On the south coast there are extensive plains. Fully one hundred rivers and streams empty themselves into the Caribbean, but the greater number of them are not navigable and in flood time they become raging torrents. In 1911 the population, of whom only 2 per cent are white, was estimated at 831,123. It is made up of Maroons, descendants of the slaves of the Spanish; descendants of African negro slaves; a mixture of British and negro; laborers from India; a sprinkling of Chinese, and the white settlers.

On the coast the climate is hot and humid, but at the higher elevations it is mild and delightful. The temperature at Kingston and the low sea-level region generally ranges between 70.7 degrees and 87.8 degrees Fahrenheit. At Cinchona, which is 4907 feet high, it runs from 57.5 degrees to 68.5 degrees. With rare exceptions, rain falls during every month in the year, and there are two wet seasons, each of about three weeks duration, one in May and one in October. The amount varies considerably; the yearly average for Kingston is 32.6 inches, for Cinchona 105.5 inches and for the entire island 66.3 inches. Hurricanes, which were of frequent occurrence during the early part of last century, have not visited the island so often of late years. Earthquakes take place from time to time, that of 1907 having been particularly violent and destructive.

Transportation facilities are excellent, the roads are good and a railway 180 miles long connects Port Antonio, Kingston and Montego bay.

Jamaica was discovered by Columbus on May 3, 1494, and was called Santiago by him, but this never supplanted the original Indian name Jaymaca, “the island of springs,” modified into its present form, Jamaica. Columbus put in at the island for shelter in 1505, and four years later his son Diego sent out Don Juan d’Esquivel to take possession of it in the name of the Spanish crown. Sant’ Iago de la Vega, now Spanish Town, founded in 1523, was destroyed by the British in 1596 and was rebuilt after their departure. The British raided the island again in 1635, and twenty years later they occupied it permanently, expelling the Spaniards entirely by 1658. During the three years that followed, Jamaica was under military rule and then a constitution modeled upon that of the mother country was established.

About this time the island became a rendezvous for the buccaneers. These gentry quite often combined the roles of merchants or planters and pirates or sea-rovers. In 1670 the treaty of Madrid confirmed the British in their possession of the island and the buccaneers were suppressed. Jamaica then became a great slave market, and the growing of sugar cane and the manufacture of sugar on an extensive scale were begun. Civil disturbances retarded the progress of the colony until 1728. The town of Port Royal was destroyed by a great earthquake in 1692, while in 1712 and 1722 hurricanes of extreme violence carried destruction throughout the island.

When the Dutch were driven from Brazil by the Portuguese in 1655 many of them settled in Jamaica, Barbados and other West Indian islands. They brought their slaves with them, and, besides, they had a good knowledge of sugar and the necessary capital, so that the industry entered a new phase of development after their arrival. The keenest competitors of the British islands were the French sugar producers of Saint Dominique, Guadeloupe and Martinique, as they were more skilled in manufacturing methods and made sugar at a lower cost. A heavy export tax affected the sugar trade of Jamaica and her sister colonies adversely. The refining of sugar was prohibited and heavy import duties placed upon sugar and syrup entering British North American possessions closed that market to the Jamaican product. Notwithstanding these drawbacks the industry continued to grow and in 1791 the destruction of the plantations of Saint Dominique removed a formidable rival.

Since the passage of the emancipation act in 1834 and the granting of £16,500,000 as partial indemnity to the planters for the loss of their slaves, there has been persistent agitation by the planters, both in Parliament and outside of it. It became very loud when the protection afforded West Indian sugars as against sugars raised in slave-owning countries was lessened and finally withdrawn. It subsided somewhat with the abolition of slavery in the colonies of other European nations, and it was renewed with added vigor when the competition of bounty-nourished beet-root sugar manufactured on the continent of Europe made itself felt. As has been shown, bounties and cartels enabled the European beet-sugar manufacturers to sell their product in foreign markets below actual cost, while realizing a handsome profit in the quantity sold for home consumption. Jamaica and the other cane-producing colonies which had no domestic trade to fall back upon found themselves in a grievous plight.

By 1895 matters had reached such a pass that a royal commission was appointed to make a thorough investigation of conditions and report to the home government. The main features of the remedial measures adopted as a result of the work of this body were:

First: The establishing of the farmers as owners of land, that is to say, parcels of land were sold to small farmers, who were assisted by money advances in the cultivation of their crops, with the understanding that they were to grow cane at their own risk and sell it to the mills.

Second: Planters were encouraged to raise crops other than sugar.

Third: Agricultural experiment stations were built and equipped in Barbados, Trinidad and Jamaica with sub-stations in a number of the smaller islands.

Fourth: A direct steamship service to Canada was established. The service between Jamaica and England was improved and regular steamer communication between the islands was provided.

It was stipulated that the cost of building and maintaining the experiment stations was to be borne by the home government until the results obtained justified their being supported by the colonies. In addition, a grant of money was authorized by Parliament to take care of the pressing needs of the planters during the year before the Brussels convention became effective.

With improved steamship facilities between Jamaica and the mother country, the volume of the trade in fresh fruit was greatly increased.

[Illustration: _Photo by H. H. Cousins_

MORELANDS SUGAR MILL, VERE, JAMAICA]

[Illustration: THE FLEET, MORELANDS, VERE, JAMAICA]

In 1907 the value of the fruit shipments in pounds sterling was as follows:

Bananas £842,689 Citrus fruits 90,468

as against

Sugar 122,328 Rum 98,923

On January 14, 1907, an appalling earthquake occurred. The buildings in Kingston and Port Royal were destroyed or badly damaged and about one thousand people were killed.

In 1906 the area under cultivation in Jamaica was 750,000 acres and of this only 26,000 were devoted to cane. Sugar planting has been in a stagnant condition for years and only a limited number of the estates that still carry on the industry are making money. Many have stopped growing cane entirely and have turned to bananas, cocoanuts, coffee or cattle raising. In certain districts there is plenty of fertile alluvial land, ample water and cheap labor, but proper cultivation is lacking, so that the results are far from what they should be. Planting simply consists of sticking a piece of cane stalk in a hole in the ground and very little ploughing is done, consequently the weeds are never under control. It takes about twelve months for the cane to ripen and the yield per acre varies widely, ranging from ten to forty-five tons. The average may be taken as about twenty tons per acre.

The island boasts of three central factories and eighty-two small mills, only twelve of the latter having vacuum pans. The others make muscavado sugar and rum. In the operation of boiling by no means all of the sugar is extracted, as a pure liquor is needed for the manufacture of good rum and quite a large amount of cane juice is made into rum direct.

In the process of making muscavado sugar in Jamaica, the cane juice after being brought to boiling point in an open kettle is transferred into a second kettle, where it is treated and the heavy impurities allowed to settle. The clear juice then goes into copper walls, a series of three or more large open copper pans, called teaches. These pans rest above an open fire fed by bagasse, cane trash and wood. After the juice has been boiled to a certain density in the first pan it is transferred to the second and the final concentration takes place in the third or fourth, as the case may be. In some mills the last boiling is done with steam in what is called an Aspinall pan, instead of over an open fire. When the mass becomes sufficiently thick, it is put into large tanks and left to crystallize. Sometimes it is kept in motion during crystallization, but usually no stirring whatever is done. Crystallization completed, the mass is packed in hogsheads with perforated bottoms. These hogsheads are allowed to stand over drainage troughs for two or three weeks so that the molasses may run off. The holes are then plugged up and the sugar is ready to be shipped.

The percentage of sugar, glucose and water in Jamaica muscavados is approximately:

No. 1 Sucrose 88.6 Glucose 5.30 Water 3.42 2 86.2 4.40 3.72 3 83.9 5.92 4.66 4 83.0 6.98 3.84

Management is slipshod and the extraction is poor. It takes fifteen tons of cane and sometimes more to produce a ton of sugar.

As for the future of the sugar industry in Jamaica, much in the way of improvement could be done by the introduction of systematic management, proper cultivation, adequate fertilization and scientific methods of manufacture. Labor is plentiful and cheap, and it would seem that sugar could be produced in Jamaica at as low cost as in Cuba. Thus far, however, there have been no signs of a real awakening.

As regards production, the following figures are taken from Willett & Gray:

1903-04 crop 14,255 tons 1904-05 ” 16,000 ” 1905-06 ” 18,000 ” 1906-07 exports 13,971 ” 1907-08 ” 10,718 ” 1908-09 ” 11,453 ” 1909-10 ” 12,000 ” 1910-11 ” 19,960 ” 1911-12 ” 21,835 ” 1912-13 ” 8,728 ” 1913-14 ” 15,583 ” 1914-15 ” 15,063 ” 1915-16 ” 15,000[68] tons

BARBADOS

Barbados, the most easterly of the Windward islands, lies seventy-eight miles east of St. Vincent in 13 degrees 4 minutes north latitude and 59 degrees 37 minutes west longitude. It is twenty-one miles long, fourteen and one-half miles at its greatest breadth and its area is 166 square miles. It is of coral origin and at certain points the coral reefs extend out to sea as far as three miles and are a menace to navigation. The island is low and flat, except in the central and northeastern part. Mount Hillaby, the highest peak, rises 1148 feet above sea-level and from it the land slopes in terraces in every direction. Carlisle bay on the southwest is a natural harbor, but only available for vessels of light draft. Barbados is densely populated. In 1906 the number of inhabitants was 196,287, of whom by far the greater number were negroes, who, in proportion to the whites, are as nine to one.

The climate is agreeable, with well-defined wet and dry seasons, and for eight months in the year the heat is modified by the northeast trade winds. The dry, or cold, period is from December to May. The temperature ranges from 70 degrees to 86 degrees Fahrenheit, seldom falling below 65. There is a plentiful rainfall, the annual average being sixty inches, and September is the wettest month. Moisture readily penetrates the coral subsoil and collects in subterranean reservoirs. Porous soil, thorough cultivation and the absence of swamps give miasma no opportunity and fever is unknown, but hurricanes are the scourge of the colony. The soil is thin, but extremely fertile, and there is a theory that it was originally formed of volcanic ash, carried by the winds from St. Vincent during times when La Soufrière was in eruption.

It is said that the Portuguese were the first Europeans to visit the island; be this as it may, they never took possession of it. A British ship touched there in 1605, and, finding no inhabitants, annexed it in the name of King James I. Since that time British ownership has continued without interruption. An actual settlement was established in 1625, in which year the king made a grant of the island to Lord Leigh, afterward the Earl of Marlborough. Bridgetown, the present capital, was founded in 1628.

Barbados was the first of Great Britain’s island colonies to grow sugar cane. The plant was brought there in 1642 during Philip Bell’s governorship, and slaves were imported at the same time. A number of Dutch who were expelled from Brazil in 1655 took refuge in the island, and their knowledge of sugar and experience in its manufacture did much to stimulate the industry. Beginning with the middle of the seventeenth century, Barbados became an important sugar-producing center.

Following emancipation in 1834, the Barbados planters received £1,720,000 to indemnify them for the loss of over 83,000 slaves. At the same time a large number of the freed blacks continued to work on the sugar plantations as before, but under pay; hence abolition did not bring on the same hardships in Barbados as it did in some of the other West Indian colonies.

Labor is plentiful and cheap, so that cultivation is done carefully and in a thorough manner. The naturally rich soil is treated with fertilizers of various kinds, and planting is done every year as a rule, although ratoon crops are often raised on the uplands. Formerly Bourbon cane was grown exclusively, but owing to the falling off in the yield, it was discontinued and the varieties now in favor are White Transparent and seedling canes raised locally. The crops suffer from time to time through hurricanes and droughts, as well as from the common run of cane diseases. Of the entire area of 106,470 acres, about 100,000 acres are cultivated; between 60,000 and 70,000 acres of this are in sugar cane.

In 1902 there were 440 estates on the island, the average area being 168 acres. Of these, 23 exceeded 500 acres and 139 contained less than 100 acres; 19, comprising 6707 acres, were owned by corporations. Each estate had its own mill, and 432 of them made muscavado and eight of them centrifugal sugar. Today the number of factories is estimated at 335, of which 221 are driven by windmills. A few plants are equipped with vacuum pans and modern machinery, but muscavado sugar and molasses still represent nearly all of the production. The molasses obtained in the open-kettle process has a higher value and finds a much readier sale than that resulting from boiling in vacuum pans. Therefore in making comparisons between the yield in sugar from the open-kettle process with that from the vacuum-pan method, the increased price brought by the rich-flavored molasses made in the old-fashioned way must be taken into account.

On an average, the sugar content of the cane is 13.5 per cent and the recovery is about 7.5 per cent muscavado sugar and 3.5 per cent molasses. It is evident that imperfect crushing and crude manufacturing methods cause a considerable loss in sugar on most of the estates.

In 1898 the Imperial Department of Agriculture established its chief West Indian station in Barbados. This station has rendered great service to the planters in improving cane varieties, giving expert advice concerning fertilizing and fighting cane pests.

Undoubtedly much could still be done to better conditions, but the small estates are generally mortgaged and their owners are in no position to borrow more money to enable them to operate on a more extended scale. On the other hand, they are extremely tenacious of their holdings and will not part with them to capitalists who might establish large central factories. It therefore seems altogether improbable that there will be any expansion in the sugar industry of the colony in the near future.

The production of Barbados during the last twenty years in long tons has been as follows:

1895 33,331 1896 45,170 1897 51,275 1898 46,878 1899 40,442 1900 44,250 1901 56,912 1902 45,576 1903 33,795 1904 55,785 1905 41,210 1906 50,630 1907 33,033 1908 31,353 1909 15,571 1910 36,389 1911 32,514 1912 exports 30,548 1913 ” 11,479 1914 ” 33,387 1915 ” 32,578 1916 ” 50,000[69]

TRINIDAD

Trinidad lies six miles off the northeastern coast of Venezuela, between 10 degrees 3 minutes and 10 degrees 50 minutes north latitude and 60 degrees 39 minutes and 62 degrees west longitude. Its average length is forty-eight miles, it is thirty-five miles in width and has an area of 1754 square miles. It is the largest of the British West Indian islands, with the exception of Jamaica, and the population in 1914 was estimated to be 255,148, one-third of whom were East Indians.

The surface is level or rolling, with a mountain range in the north, which rises to 3100 feet at its highest point, Tucuche Peak. In the south there is a ridge of hills about 600 feet high, and in the central part an upland belt runs from east to west by south. There are a number of small rivers, none of them navigable.

The island enjoys an equable climate, the temperature varying from 70 degrees to 87 degrees Fahrenheit, the mean being 78.6 degrees. The seasons are regular, rainy from May to January, with a four weeks’ interval of fine weather in October, and dry from the end of January until May. The average rainfall is 66.26 inches, but in the cane-growing region it is about 80 inches. Hurricanes, earthquakes and long spells of drought are unknown.

Christopher Columbus discovered Trinidad in 1496 and the Spaniards occupied it ninety years later. It remained in their hands until 1797, when it was taken by the British, to whom it was formally ceded in 1802.

As was the case in other West Indian islands, the aborigines were quickly exterminated by the Spanish conquerors and their places filled with negro slaves. A number of French and Creole settlers came to Trinidad in 1780, and about the middle of the following century Portuguese refugees from Madeira joined the colony. After the abolition of slavery by Great Britain in 1834, many Hindus were brought in under contract.

The soil of the island is very rich and well adapted to the growing of sugar cane and other tropical products. The sugar plantations are found in the level country bordering on the Gulf of Paria, where the soil is a dark clay, and which has been described as one of the finest stretches of sugar land in the West Indies.

As a result of the financial distress of 1895, which caused the home government to pass relief measures, a number of plantation owners were compelled to dispose of a portion of their land to farmers, who grew cane upon it and sold the crop to the sugar factories. It is estimated that today about twenty-five per cent of the cane worked up by the factories is furnished by these small growers, the remainder being raised by the owners of the estates. Grinding begins in January and is finished in May or June.

Trinidad has its own agricultural station, which is chiefly devoted to the study of sugar-cane culture. It has been of great service to the industry in determining the kinds of cane that can be most profitably grown, in fighting cane diseases and pests and in working out fertilization problems.

From 1855 to 1887 an average crop of 59,774 tons was turned out by ninety estates. Of this total, 28,500 tons were vacuum-pan sugar and the rest muscavado. In 1896, 62,975 tons of sugar were made by thirty-nine estates. Seven of these made 2000 tons of

common muscavado, six made 5500 tons of centrifugal muscavado, and the remaining twenty-six made vacuum-pan sugar. A report made in that year concerning sugar estates in Trinidad sets forth that advantage has been taken of the most modern improvements in boilers, furnaces, multiple evaporators, crushing mills and other machinery. Trinidad produces a large amount of what are known as “yellow crystals,” which are sold in the British market for direct consumption and command a premium over the ordinary raw sugar.

Statistics compiled in 1909 show that the colony then had sixteen sugar factories, which turned out 52,972 tons of sugar, and the recovery represented 8.74 per cent of the weight of the cane; 451,801 tons of this cane were grown by the estates and 154,663 tons by the small farmers. There were 11,401 of the latter, 6077 of whom were East Indians and 5324 West Indians. Trinidad is the only West Indian colony where the attempt to fill the places of negro laborers with coolies from India has been successful. The production of sugar since 1900 has been as follows:

1900 41,269 tons 1901 51,077 ” 1902 44,913 ” 1903 46,029 ” 1904 50,744 ” 1905 38,240 ” 1906 62,975 ” 1907 50,564 ” 1908 48,933 ” 1909 52,972 ” 1910 exports 44,139 ” 1911 ” 37,282 ” 1912 ” 32,557 ” 1913 ” 31,665 ” 1914 ” 47,251 ” 1915 ” 49,107 ” 1916 ” 55,000 ”[70]

SANTO DOMINGO

Haiti is divided into two unequal parts, the republic of Haiti (République d’Haiti), comprising 10,204 square miles, and the republic of Santo Domingo (República Dominicana), with an area of 19,325 square miles. It is one of the four large islands of the West Indies and lies between 17 degrees 37 minutes and 20 degrees north latitude and 68 degrees 20 minutes and 74 degrees 28 minutes west longitude. Its length from east to west is about 407 miles and its greatest width is 160 miles. The total population is 2,737,700.

The surface of the island is exceedingly mountainous, three distinct ranges traversing it from east to west. The loftiest peak, Loma Tina, near the city of Santo Domingo, reaches a height of 10,300 feet. The extensive intervening valleys are fertile and watered by numerous rivers, none of which, however, are deep enough to be navigable.

The climate is hot and humid. An average temperature for the month of January would be about 75.4 degrees Fahrenheit, for July 84 degrees, and for the year 79.2 degrees. There are no active volcanoes, but great damage is done from time to time by earthquakes and hurricanes. The yearly rainfall is abundant, averaging about 120 inches. In San Pedro de Macoris, however, where the greater part of the sugar crop of the island is grown, the annual precipitation is in the neighborhood of 60 inches. As this is not sufficient for the needs of the growing cane, the planters have to do a certain amount of irrigating, and the water for this purpose is obtained from artesian wells.

The soil of the sugar-growing territory is of porous limestone formation, which shows evidence of disturbances and upheavals due to volcanic agency. Overlying this is a deposit of decomposed vegetable matter from three to twelve inches in thickness, and there are areas where a rich black or red soil, varying from one to two feet in depth, is found.

On December 5, 1492, Columbus sighted the northern coast of Haiti and found safe anchorage there. The newly discovered island was named Española, which was afterward latinized to Hispaniola. Later still, the settlement founded by the Spaniards in the southern part under the name of Santo Domingo gave its name to the entire island. When Columbus set foot on its shores, Haiti had 2,000,000 inhabitants, who were governed by five caciques, each holding both religious and political sway over the separate kingdoms. At the outset the newcomers were received with welcome and honor, but it was not long before their tyranny caused a rupture between them and the natives. A war of extermination followed, and by 1506 the entire island had fallen into the hands of the invaders.

Left in possession of a depopulated country, the Spaniards restocked it with African negro slaves. Meanwhile the interior of the island had been explored, settlements had been established, mines opened up and progress made in agriculture. In 1506 sugar was brought in and its cultivation soon assumed important proportions. About 1625 the French and English began to give trouble to Spain in the western archipelago, and a few years later a number of Englishmen and Frenchmen, who had been expelled from St. Kitts by the Spaniards, took refuge on Tortuga island and became famous under the name of Buccaneers. They succeeded in establishing themselves in a part of Haiti, and in 1697 their right of possession was acknowledged and the territory occupied by them was ceded by Spain to France by the treaty of Ryswick. The new colony was called Saint Dominique, and it entered immediately into an era of prosperity in which the expansion of the sugar industry was the principal factor. When the French revolution broke out, the exportations of sugar amounted to 80,000 tons, and this large production necessitated the employment of

a great number of slaves. The whites were few and the unequal proportion led to disaster. The population consisted of whites, free colored people (most of whom were mulattoes) and negro slaves. The mulattoes demanded the same civil rights as the white people and these privileges were accorded them in 1791. Incensed beyond measure, the whites clamored loudly for a reversal of this decree and finally obtained it. On August 23, 1791, a violent insurrection of the blacks broke out; the plantation slaves were joined by the mulattoes and a massacre of the whites followed. Those who escaped the slaughter fled, leaving all their possessions behind; the sugar plantations were destroyed and the entire sugar industry came to an abrupt end.

In 1793 Saint Dominique was attacked by England and Spain, whereupon the French government, in order to conciliate the blacks and retain its dominion over the colony, proclaimed all the slaves free. By the terms of the Peace of Bâle in 1795, the whole island passed into the hands of the French.

Toussaint Louverture, a negro of marked military ability, was appointed commander-in-chief by the directory, and by 1801 he succeeded in restoring order. Unfortunately, the measures that he endeavored to put into effect aroused the suspicions of Napoleon, who sent out an army to subdue him and to restore slavery. This expedition met with such determined resistance that the commander, General Leclerc, opened negotiations and Toussaint was induced by solemn promises to lay down his arms. He was treacherously seized and taken to France, where he died in 1803. The blacks immediately renewed hostilities under Jean Jacques Dessalines, and in November, 1803, the French withdrew completely. In the following year the independence of the island was declared and its ancient name of Haiti was restored. Dessalines was first made governor for life and in October, 1804, he proclaimed himself emperor. He was assassinated in 1806. From that time to the present the country has been in a state of turmoil and the end is not yet. In 1844 the people of the eastern end of the island seceded and formed the republic of Santo Domingo. Ever since then there have been two distinct governments in the island, with the strongest political antipathy existing between them.

But little sugar cane is raised in Haiti, and the most of this small quantity is either consumed as cane or made into a beverage called _tafia_.

The sugar plantations of Santo Domingo are found on the southern coast, in the level stretches of Arua and Romana, in the valleys near the city of Santo Domingo and in the region near San Pedro de Macoris. No sugar is grown in the interior. While most of the factories are land owners and cultivate cane, they do not grow all that they grind. A good deal is raised by colonos under the following conditions: The factories assign parcels of land to the colonos rent-free and in addition allow them the use of draft cattle and farming implements. When necessary a certain amount of actual cash is advanced. The colonos plant and till the land, furnish their own labor and deliver the cane at the point where it is loaded on the railway cars. The field hands are either natives or negroes brought from nearby islands, and their pay ranges from 50 to 75 cents gold per day.

The ground is tilled in an indifferent fashion and no fertilizing whatever is done. When virgin soil is planted, the seed is put in at seven-foot intervals, sometimes greater, without any holes or furrows having been made; the cuttings are simply stuck in the ground and partly covered with earth. The cane ripens in fourteen months or more. Ratooning follows until the yield gets so small that replanting is necessary. When this time comes, the old roots are ploughed up and furrows from four to six inches in depth are made about five or six feet apart. The seed cane is planted in these furrows at four- or five-foot intervals. The yield from virgin soil is very heavy and has been known to reach ninety tons to the acre, but the sugar content of such crops is low, whereas the subsequent ratoons with a decreased tonnage of cane per acre give juice of a better quality. A fair average production on a plantation having 4000 acres in cane would be about twenty-four tons to the acre. Naturally this estimate would be affected by the relative proportions of plant cane and ratoons, as well as by the character of the soil. Planting is generally done in June and October, while the harvesting begins in December and continues until April.

Manufacturing methods in Santo Domingo admit of much improvement. Single crushing is the method employed for the most part, so that the loss in extraction is considerable. The juices are treated and the suspended impurities allowed to settle at the bottom of the tanks. Filter presses are the exception rather than the rule, and for want of them the sugar in the resultant mud is lost. The clear juices are then concentrated and boiled to grain in vacuum pans. First sugars generally polarize between 95 degrees and 97 degrees, seconds about 86 degrees. The molasses is either made into rum or permitted to run to waste. Notwithstanding the crude character of the factories and machinery, the recovery of sugar is generally good, the average being between 9 per cent and 11 per cent of the weight of the cane, with single crushing.

Almost all of the factories are managed by Americans, but, as has been said, the equipment they have to work with is by no means modern, and under the extremely uncertain political conditions that prevail there is scant encouragement for outside capital to come

in and improve matters. Just when a change for the better will come is impossible to say.

Messrs. Willett & Gray give the yearly figures since 1903 in long tons, as follows:

1903-04 47,000 1904-05 47,000 1905-06 55,000 1906-07 60,000 1907-08 62,235 1908-09 69,483 1909-10 93,003 1910-11 89,979 1911-12 96,046 1912-13 84,661 1913-14 105,778 1914-15 108,267 1915-16 120,000

GUADELOUPE AND MARTINIQUE

GUADELOUPE

The French West Indian colony of Guadeloupe consists of two islands that lie in the middle of the Leeward group between 15 degrees 57 minutes and 16 degrees 31 minutes north latitude and 61 degrees 10 minutes and 61 degrees 49 minutes west longitude. They are separated by a channel from one hundred feet to four hundred feet wide, called Rivière Salée.

Basse-Terre, the western island, is twenty-eight miles long, from twelve to fifteen miles wide and its area is 364 square miles. It presents a rugged surface, broken by hills and highlands, and a backbone of mountains runs through it from north to south. It is of volcanic origin, having been thrown up by four volcanic centers, Grosse Montagne (2590 feet), Les Mamelles (2536 feet and 2368 feet), Morne sans Toucher (4855 feet), and La Soufrière (4868 feet). The last-named volcano was in eruption in 1797, and in 1843 its disturbances wrecked several towns; today, however, the only evidences of life are a few hot springs and the emission of sulphurous vapors at certain points.

Basse-Terre is watered by a number of streams that become swollen and turbulent during the rainy season.

Grande-Terre, the eastern island, is low and level, the greatest elevation being only 450 feet. It consists of a plain of limestone formation with a conglomerate of sand and broken shells. It is about twenty-two miles long from north to south and its area is 255 square miles. The population is 190,273, chiefly negroes and mulattoes. For water supply it is dependent upon ponds and cisterns, as, owing to the porosity of the soil, no rivers or streams exist.

The climate is warm and humid. The mean yearly temperature is 78 degrees Fahrenheit, the minimum 61 degrees and the maximum 101 degrees. The wet season is from July to November, and on the coast the annual rainfall is about eighty-six inches, with a great deal more in the interior. Terrific storms visit the island and hurricanes have wrought much destruction.

The soil is fertile and rich and the principal crop is sugar cane, which is grown on over half the total cultivated area. The principal sugar centers are Point-à-Pitre, St. Anne and Le Moule in Grande-Terre, all of which have well-appointed usines. There is also a large usine in Basse-Terre.

Guadeloupe was discovered by Columbus in 1493. One hundred and forty-two years afterward l’Olive and Duplessis took possession in the name of a French company called the Compagnie des Iles d’Amérique. The native Caribs did not long survive the cruel treatment accorded them by l’Olive, and efforts at colonization were the reverse of successful, in fact four chartered companies were ruined in the attempt. In 1674 the islands passed into the possession of the French crown and they were governed from Martinique for a long time. In 1759 they were captured by the British, in whose hands they remained for four years. The British again occupied them in 1794, but were driven out the following summer by Victor Hugues with the help of liberated slaves. The last British occupation took place during the Hundred Days of 1815, and they finally withdrew in 1816. Slavery in Guadeloupe was abolished in 1848.

MARTINIQUE

The French colony of Martinique is the most northerly of the Windward islands. It is situated between 14 degrees 55 minutes and 14 degrees 23 minutes north latitude and 60 degrees 48 minutes and 61 degrees 16 minutes west longitude. Its area is 381 square miles, its greatest length from northwest to southeast 36 miles, and its extreme width 18 miles. The population, negroes and half-castes for the most part, numbered 190,000 in 1913.

The surface is mountainous, the highest peak being Mt. Pelée, which rises 4428 feet above sea-level. The appalling eruption of this volcano in May, 1902, was one of the greatest disasters of modern times and cost the lives of 40,000 people. About one-third of the island’s surface consists of extensive plains, most of them occurring in the south. The soil of the northern part is of volcanic formation, while in the south it is composed of clay. There are a number of streams, some of them of considerable size.

Near the coast the average temperature for June is 83 degrees, and for January 77 degrees, the mean for the year being about 80 degrees Fahrenheit. The wet season extends from June to October and the total yearly rainfall approximates 87 inches. August is the wettest month and March the driest. In the low region of the sea coast the climate is not healthful for Europeans during the hot period, but a more salubrious atmosphere and a temperature 10 degrees lower is found in the wooded uplands, 1500 feet above the sea. Fresh, dry northerly winds prevail from November to February, easterly winds from March to June, and damp, warm southerly winds from July to October. Earthquakes are frequent, but hurricanes seldom visit the island.

Martinique was discovered by Columbus on June 15, 1492, and the French Compagnie des Iles d'Amérique took possession of it in 1635. It was settled in the same year by Pierre Belain, captain-general of the island of St. Christopher, and in 1674 it became the property of the crown.

Sugar culture was begun in 1650, and a few years later the aboriginal Caribs were exterminated, their place being filled by negro slaves, of whom there were 60,000 in the island by 1736. Slavery was abolished in 1848.[71]

During the seventeenth century Martinique was attacked several times by the British and the Dutch. It was captured in 1762 by the British under Admiral Rodney, but restored to the French in the following year. It was held by the British from 1793 to 1801 and also between 1809 and 1814.

The capital of the island is Fort de France, on the west coast. It is situated upon a fine harbor and has 18,000 inhabitants. Besides the chief product, sugar, the colony raises coffee, cocoa, tobacco and cotton.

GUADELOUPE AND MARTINIQUE

Sugar planting in these islands dates from 1635, the year in which they were first occupied by the French, and the industry grew apace, so that much sugar was exported to France during the latter half of the seventeenth century. The import duties levied by France in 1664 shut out foreign raw sugars from that country, while protecting raw sugars from her colonies; but at the same time the tariff laws excluded white sugar produced in the colonies. This was a death blow to the refineries of Martinique. A decree entirely prohibiting the refining of sugar in the colonies and the exportation of raw sugar to foreign countries was issued in 1669, while an export duty was imposed upon the raw sugar shipped to France. The tax upon raw sugar was removed in 1682, but the duty on refined was increased. The colonial planters then turned their attention to the manufacture of clayed sugars, which they sold in North America and southern Europe.

In 1717 France established relations with her colonies that were almost tantamount to free trade. No duties were assessed upon French goods going into the colonies, and commodities produced in the colonies entered the mother country without duty. As a result of this policy, the sugar industry grew until the production of Guadeloupe, Martinique and Saint Dominique was more than France could consume, and a law was passed permitting the sale of the surplus in other countries.

During the closing years of the eighteenth century, the war between England and France crippled the trade of the French West Indies, but when peace was finally restored the sugar industry revived and continued to flourish until the abolition of slavery in 1848.

When the slaves were freed, the planters cast about them to find laborers, and India was one of the first sources of supply. Over ten thousand Hindus were brought to Martinique between 1852 and 1862, and with very few exceptions they remained in the island after their five-year contract expired. During the twenty-two years that followed 1862, 25,500 laborers came to Martinique from Pondicherry, Yanaon, Karikal and Calcutta with the permission of the Indian authorities, but emigration from that country under government auspices was discontinued in 1885. In addition to Hindus, free African negroes, Chinese and Annamese were brought in.

The sugar plantations of Guadeloupe and Martinique are situated on the low, alluvial lands around the coast, although some are found in the interior. The hilly character of the latter, however, is not favorable to cane culture, as the heavy rains wash the arable soil down the slopes, thus interfering with the growth of the cane.

The ground to be planted in cane is first cleared and then ploughed. Furrows about two feet deep and four and one-half feet apart are then made and the seed cane is planted in holes five inches deep. Three weeks afterward the cane is banked and fertilizer applied. The soil between the canes is loosened from time to time and the crop is cut after a year's growth. As a rule, ratooning is limited to two years, one crop being produced each year. The land is then allowed to rest for a time, after which planting is begun

anew.

Bourbon cane is the variety principally grown, although seedling canes have been brought in from Barbados and British Guiana of late years. The average yield per acre of plant cane is twenty-four tons; first ratoons give sixteen tons and second ratoons about eight tons. After the cane is cut it is loaded on large carts and taken to the factories. Some estates are equipped with field railways, the cars being drawn by mules or locomotives.

As mentioned in the chapter on Jamaica, the early sugar producers of Saint Dominique, Guadeloupe and Martinique excelled the manufacturers of the other West Indian islands in the preparation of the commodity. The result was that their lead was gradually followed by the others, and a brief description of the methods they employed will be of interest.

The cane juice was boiled in a series of five or six copper kettles placed over a furnace fed by bagasse and wood. These kettles were of different sizes, the largest being farthest from the fire and the size of each decreased as the furnace door was approached, the smallest being directly above the fire. The kettle next to the largest was set a little higher than the largest one, the third higher than the second and so on until the last and smallest, which was the highest of the series. Clarification was done with lime and wood ashes, and sometimes a little crude antimony. As soon as the raw juice reached the first and largest kettle the clarifying material was thrown in and the boiling began. The scum was removed as soon as it formed, and when the juice became sufficiently clear it was quickly transferred to the second kettle; a small amount of alkali was mixed with it and further boiling and skimming was done. The liquor was then ladled into kettle number three, potash lye and an extract of herbs were added, and after being boiled for a time it was passed to kettle number four, and finally concentrated in the last and smallest kettle immediately above the fire. When the required consistency was reached, the massecuite was put into vessels to cool, at the same time being kept in motion by stirring until the grains began to form. It was then placed in moulds, and after having become thoroughly cool it was dumped into hogsheads that had perforated bottoms. These hogsheads stood on racks, beneath which there was a receptacle to catch the molasses as it drained on through the holes in the bottom. The draining was allowed to continue until about one-half the weight of the contents of the hogshead was crystallized sugar. The holes were then plugged up and the sugar was ready for shipment. The molasses was manufactured into rum.

A superior grade, called _sucre terré_, or clayed sugar, was also made. In its preparation, juice from the best and ripest cane was taken and as little lime as possible was used in clarification. Antimony was excluded entirely, on account of its tendency to darken the color of the juice. As the juice was transferred from kettle to kettle during the various boilings, it was strained through a cloth each time, instead of being ladled direct from one kettle to the next. When the syrup was concentrated it was put into earthenware sugar-loaf moulds that held between thirty and thirty-five pounds of massecuite apiece. These moulds had perforations in the bottom that were stopped up before the mass was put in. In filling a mould, one quarter of its capacity was put in at one time, making four operations. Fifteen minutes after the last lot of massecuite was put in the mould, a layer of crystals formed on the surface, and this was thoroughly stirred into the mass, which was then left to cool. A couple of days later the plugs were removed so that the molasses might drain from the mould. In case it did not run off properly, the massecuite was remelted, but if the drainage was satisfactory, the next step was the claying of the sugar. If the top of the loaves was uneven or dark-colored, it was scraped smooth and covered with a layer of crushed sugar. The surface was then hammered level and even. A special kind of clay brought from Rouen was mixed with water and the mould was filled to the top with this mixture. Windows and doors were shut to prevent evaporation of the moisture, and the water draining from the clay gradually passed down through the sugar crystals, washing the syrup from them. After ten days had elapsed, the clay, then thoroughly dried, was removed, the surface of the sugar-loaf was cleaned, another layer of wet clay was applied and allowed to remain as long as the first. When this second layer was taken off, the loaves were removed from the moulds and allowed to dry in the air for a time. Further drying was done in a drying room, heated for the purpose, and the sugar, when all the moisture had been driven from it, was crushed by wooden pestles. Refined sugar was packed for shipment in casks containing between 600 and 700 pounds. The first molasses was made into rum or boiled into second sugar, and the syrup washed from the loaves was made into a sugar called _cassonade_.

This primitive method of manufacture has been entirely supplanted by newer processes and appliances. As a rule, today cane is crushed twice and maceration is often employed. The juice is treated with sulphur while still cold, and it is then pumped into defecation tanks, where powdered lime is added; after this is done heat is applied. As soon as the scum cracks, the steam is turned off and the clear juice is separated from the sediment by a siphon and run to the evaporators, while the muddy precipitate goes to the filter presses.

Concentration of the juice takes place in double, triple or quadruple effects of rather an old type, which means lack of economy in steam and consequent large fuel consumption. As the quantity of bagasse available does not afford sufficient fuel to generate all the steam that is required, a considerable amount of wood and coal is used in addition for the purpose. The unwise and short-sighted policy of denuding the hillsides of their timber has had the effect of lessening the rainfall, a condition that has brought great injury to the planter.

The vacuum pans are small and of old style; the centrifugal machines, too, are of obsolete design and slow to operate. After the liquor has been boiled to grain in the pans and the sugar crystals have been separated from the mother liquor in the centrifugals, the sugar is dried and packed for the market in barrels or bags. The first molasses is reboiled and the resulting massecuite sent through the centrifugals. After this operation has been repeated three or four times, the final molasses is made into rum.

Today there are eighteen factories in Guadeloupe and fifteen in Martinique. The average extraction of sugar is 9.70 per cent of the weight of the cane, the loss of sugar in the bagasse is 2.15 per cent, the mechanical loss in manufacture is .90 per cent, and the percentage of sugar not recovered from the molasses is 1.75. This gives an average total of 14.50 per cent of sugar in the cane.

The manufacturers are dependent upon the small farmers for their raw material, and the price paid for the cane is determined by a very complex agreement, which nevertheless seems to be entirely satisfactory to both buyer and seller.

The outlook for the sugar industry in Guadeloupe and Martinique is far from bright. There is labor in abundance, but the natives are averse to working steadily, and consequently are unreliable. There are great possibilities for improvement, but little can be expected under the circumstances that prevail at the present time.

Since 1894 the production of the two islands in long tons has been as follows:

MARTINIQUE GUADELOUPE 1894 36,353 42,395 1895 28,777 29,394 1896 33,886 42,616 1897 34,185 39,493 1898 30,971 36,550 1899 31,165 39,259 1900 33,234 27,895 1901 39,121 38,086 1902 38,905 39,995 1903 28,578 37,891 1904 23,561 35,348 1905 29,986 26,905 1906 42,231 42,535 1907 36,764 38,345 1908 35,943 35,485 1909 37,757 24,812 1910 39,950 44,289 1911 35,438 38,384 1912 39,433 39,368 1913 40,000 32,000 1914 38,730 39,920 1915 40,000 40,000 1916 40,000 40,000

MEXICO

The United States of Mexico lie between 14 degrees 30 minutes and 32 degrees 42 minutes north latitude and 86 degrees 46 minutes and 117 degrees 7 minutes west longitude. On the north the boundary is the United States of America; on the east the Gulf of Mexico, the Caribbean sea, British Honduras and Guatemala; on the south British Honduras and the Pacific ocean, and on the west the Pacific ocean. The superficial area of the country is 765,537 square miles. Its greatest length is 1942 miles and its greatest width is 762 miles. It has a coast line of 5486 miles, of which 1603 miles are on the Gulf of Mexico and the Caribbean sea and 3883 miles on the Pacific ocean and the Gulf of California.

The surface of Mexico rises sharply from the seacoast levels by a series of terraces to a central plateau, that varies in height from 4000 to 8000 feet and runs northwest and southeast. This tableland has been formed by the material deposited during the gradual erosion of the mountains and by matter thrown up by a great number of volcanoes. In this manner the original valleys became completely filled up and those that now exist are of later formation. To illustrate this filling process, buried mountains whose peaks appear above the surrounding mass are found in the higher parts of the plateau, while elsewhere they are met with as continuous ridges. The eastern coast is low and sandy, except in a few places where the mountains come down close to the shore. The Pacific coast lands are also low, but occasionally broken by mountain spurs. Owing to the terraced character of the country, very little river navigation is possible, but on the other hand an enormous amount of power can be developed from the numerous waterfalls. Two high mountain ranges, one on each coast, run parallel to the sea the entire length of Mexico. The eastern chain is about ten miles inland, while on the west there is only a narrow shelf of land between the sea and the cordilleras. This western range has several branches that run in different directions, the most important being the Sierra Madre Occidental. In Mexico the highest mountains are volcanoes. On the Pacific side and west of the plateau are found the Volcán de Colima (12,750 ft.) and the Nevado de Colima (14,354 ft.). Southwest of the City of Mexico is the Nevado de Toluca (16,610 ft.) and to the south and east are the snow-crowned giants Popocatepetl (17,540 ft.) and Ixtaccihuatl (15,705 ft.). Still farther east are Orizaba (16,176 ft.) and Cofre de Perote (14,309 ft.). Popocatepetl and Orizaba may be classified as dormant cones, for the reason that aqueous and sulphurous vapors are constantly being emitted from their perfectly formed craters. One of the highest lakes in the world is found in the crater of the Nevado de Toluca. Colima has been in eruption continuously for many years and is still active. The snow never leaves the summits

of Orizaba, Popocatepetl and Ixtaccihuatl, and on the last the ice cap attains a development sufficient to form true glaciers.

On the western coast the principal ports are Guaymas, Mazatlan, Topolobampo, Acapulco, La Paz and Salina Cruz; on the eastern seaboard, Tampico, Vera Cruz, Puerto Mexico, Campeche and Merida. Of the numerous rivers, the most important is the Rio Grande, 1550 miles long, which forms a natural boundary between Mexico and the United States from El Paso to the Gulf. However, the conformation of the country does not admit of river navigation to any extent.

According to the census of 1910, the population was 15,063,207, of which 20 per cent were whites, 43 per cent of mixed blood and the remainder of Indian extraction.

In Mexico there are three distinct climates and a wide range of temperature. The hot country, _tierra caliente_, extends from the seacoast inland to an altitude of about 3000 feet. Here the mean annual temperature is between 80 degrees and 88 degrees, and the highest between 100 degrees and 105 degrees Fahrenheit. In this region the winter climate is delightful, except when severe gales sweep down from the north. In summer the extreme heat is not so great as in New York, because of the moderating effect of cool breezes.

The temperate region, _tierra templada_, extends from 3000 to 6500 feet above sea-level, and it is here that the ideal climate of Mexico is found, the mean annual temperature being between 73 and 77 degrees Fahrenheit, with a total variation of possibly not over 6 or 8 degrees during a season. In this dry, clear atmosphere the hygienic disadvantages of the seacoast, the sharp, cold winds of the upper altitudes, sudden changes in temperature, heavy frosts, extreme humidity and harmful insects are unknown, and in the dry season there is no malaria.

Tropical and semi-tropical growths flourish side by side, and there are estates on which wheat and sugar cane are raised almost in touch of each other.

The cold country, _tierra fria_, extends from the 6500-foot level to the snow line, but here the term cold is used in a comparative sense, as distinguished from the heat of the seacoast. The average temperature runs between 59 degrees and 62 degrees Fahrenheit, with slight variations. At times, however, a norther will drive the mercury down to 40 degrees or 35 degrees and sprinkle the streets of Mexico City with white.

As a rule, in Mexico the rainy season begins in May or June and ends in October. The annual rainfall varies greatly according to locality, ranging all the way from fifteen to fifty inches. Earthquakes are of common occurrence, especially on the western coast.

Sugar cane was brought to Mexico by the Spanish conquistadors. Prescott, in his “Conquest of Mexico,”[72] says that the sugar cane was transplanted from the neighboring islands to the lower level of the country, and that, together with indigo, cotton and cochineal, it formed a more desirable staple for the colony than its precious metals. He also states that it was Hernan Cortés himself who introduced the cane from Cuba. This famous soldier established the Atlacomulco plantation, which lies an easy hour’s ride distant from Cuernavaca in the state of Morelos, and there, in 1520, a hundred years before the landing of the Pilgrim Fathers at Plymouth, he erected the first sugar mill in Mexico. This mill is owned by the descendants of Cortés and is still in operation.

Thirty years later sugar was shipped from Mexico to Peru and Spain, and the production of the commodity was maintained steadily until 1791. In that year all the cane-growing countries of western America received a stimulus from the wholesale destruction of the plantations and mills of Santo Domingo.

In Mexico natural conditions are very favorable to sugar culture, but the growth of the industry has been retarded by the primitive methods in vogue, the inadequacy of transportation facilities and political disturbances. In the seaboard states the sugar plantations are found chiefly in the rich lowlands bordering on the Pacific ocean and the Gulf of Mexico. In the Gulf states the rainfall is ample to insure good crops. The largest sugar producer, however, is the inland state of Morelos, and there, as well as on the west coast, irrigation is necessary. The higher levels do not give such good crops as the lowlands; on the latter the yield is between forty and sixty tons to the acre, and on the former it runs between twenty-five and forty-five tons to the acre. Sugar beets have been grown on the plateau with marked success. In the low, tropical regions seven or eight crops of ratoons can be raised, but on the higher lands replanting must be done every two or three years. The best-known plantations are situated on large estates that have been owned by the same families for many generations. For instance, in Morelos, where about sixty per cent of Mexico’s crop is produced, the estates are owned by non-resident families and, as a rule, managed by Spaniards. Labor is cheap and abundant, the cane is rich in juice and the sugar content is high, but the extraction in the small, crude mills is poor, the recovery of sugar, as a rule, not exceeding six per cent of the weight of the cane. There are a few large factories in Mexico where the methods and results

should be more closely in accordance with modern practice.

The nineteenth century saw the industry maintained on a fairly even basis, but about 1900 an improvement was noted, as the following table will show:

1899-1900 75,000 tons 1900-1901 95,000 ” 1901-1902 103,000 ” 1902-1903 112,000 ” 1903-1904 107,000 ” 1904-1905 107,000 ” 1905-1906 107,500 ” 1906-1907 119,000 ” 1907-1908 123,000 ” 1908-1909 143,000 ” 1909-1910 148,000 ” 1910-1911 161,602 ” 1911-1912 151,735 ” 1912-1913 148,672 ” 1913-1914 130,000 ” 1914-1915 110,000 ” 1915-1916 75,000 ”

The effects of the internal disturbances in Mexico are plainly reflected in the crop figures. In addition to the sugar tonnage shown, about 50,000 tons of _piloncillo_ or _panela_ (concrete sugar) are turned out annually by the small mills and the production of molasses is large. A considerable amount of the latter is used in the manufacture of rum and alcohol.

As regards the future of sugar in Mexico, there is much to justify belief in ultimate expansion and prosperity. Labor is cheap and plentiful, there are vast tracts of rich virgin land awaiting cultivation, irrigation possibilities are great, and when the present political disorders shall have been quieted and stable conditions established, a movement forward will surely follow.

PERU

Peru is situated on the west coast of South America and extends from 3 degrees 21 minutes to 18 degrees south latitude and from 70 degrees to 81 degrees 40 minutes west longitude. Its area, including certain disputed territory, is 676,638 square miles. Physically, it is divided into three distinct regions, the coast, the sierra and the montaña. In the first, or the dry side of the Andean slope, spurs run out from the main range of mountains toward the ocean, forming extensive valleys, some of which are well watered and very fertile. The spaces that lie beyond the life-giving influence of the rivers have the appearance of sandy deserts, but they only need water to make them productive. The Andes proper occupy the sierra region, which abounds in plateaus, deep ravines, rich sheltered valleys and snow-capped mountains of stupendous height. East of the Andes lies the montaña, or wet side. It is traversed by broad navigable rivers and embraces the sub-tropical forests in the ravines and on the eastern slopes of the Andes, as well as the dense tropical forests of the wide valley of the Amazon.

According to the 1915 edition of the Century atlas, the population is 4,609,999. About 57 per cent of the inhabitants are Indians, 13 per cent whites, 2 per cent Asiatics, 2 per cent negroes, the remainder being mixed races.

The sugar plantations are found on the west or dry side in the coast region.

The valleys of this coast country have been upraised from the ocean at a comparatively recent geological period, and the fertile soils of these valleys are the result of erosion and deposit through the agency of mountain torrents.

The most important cane-growing districts lie seven or eight degrees south of the equator, and yet the climate of that section cannot be called really tropical. It is influenced by the cold antarctic currents and the steady winds that sweep northward. Observations on the Cartavio plantation during the period 1904-1907 showed the highest maximum temperature to be 95.5 degrees and the lowest minimum to be 52 degrees Fahrenheit. In the coast territory the rainfall is limited and the cane crops depend upon irrigation.

The soils of the coast valleys range from silt to an extremely fine sandy loam, and vary in thickness. As a rule they are deep, retentive of moisture, well drained, rich in plant food, easy to cultivate and, with intelligent treatment, very productive.

Ricardo Palma, in his work, “Tradiciónes Peruanas,” sets forth that sugar cane was not known in Peru when Francisco Pizarro and his followers first landed there in 1527, but that it was brought in a short time afterward. The first plantation was established in 1570 and the first factory was erected on an estate in the valley of Huanuco. Meanwhile, the sugar used in Lima came from Mexico, and the owner of the Huanuco mill, realizing that his product could not compete with Mexican sugar, had recourse to a clever stratagem. He loaded a vessel with sugar and sent her to Mexico. The ruse was successful, for the Mexican manufacturers at once concluded that if sugar could be shipped from Peru to Mexico, the production must be large and the cost very low. Consequently, they discontinued their shipments from Acapulco to Peru, much to the advantage of the astute factor of the Huanuco valley. In the beginning, the estates were worked by slaves, and, as happened in other sugar countries, after the abolition of slavery the plantation owners were compelled to look abroad for their laborers. As many as 90,000 Chinese were imported from Macao[73] between 1849 and 1874, but so many of them succumbed to the severe treatment they received that the Macao authorities put a

stop to the labor traffic altogether. The Chinese living in Peru at the present time are tradespeople and the work on the sugar plantations and in the mills is done by the native Indians.

[Illustration: LEVELING A CANE FIELD, PERU]

[Illustration: LEVELING GROUND BY STEAM, PERU]

The year 1860 marked an important change in the industry, which up to that time had been carried on in a very primitive manner. A large amount of fresh capital was put into sugar enterprises, new mills were built, the most approved machinery was installed and the factories were equipped with the best appliances that money could buy. The apparatus for some of the plants was brought from the United States, while that for others was supplied by European countries, so that the methods and workmanship of various nationalities are found in the Peruvian factories. No expense was spared in any department and all went well so long as the price of sugar kept up; what was easily made was liberally administered, but when in 1875 the market dropped, severe competition drove many operators into difficulties and a number of them went under entirely. The war with Chile in 1878 and the subsequent revolutionary disturbances impeded the progress of the industry, but a restoration of tranquillity came in 1895, and since then the sugar business of Peru has prospered and increased in volume.

An experiment station was established near Lima in 1906 for the study of cane cultivation, irrigation problems and the improvement of yield and quality by the introduction of new varieties of cane. The manufacturing side of the question has also been gone into with great care, and much is being done to increase efficiency in that direction.

Today there are 47 modern factories in Peru and 125,000 acres planted in sugar cane. Outside of these modern plants, crushing is also done in a crude manner in wooden-roller mills on small plantations that are scattered throughout the interior. The juice obtained in this way is worked up to _chancaca_[74] or _panela_ or made into an alcoholic beverage called _cañaso_ or _chacta_.

As the plantations do not depend upon any special season of rainy or dry weather, planting and harvesting may be done at any time. In Peru the land upon which sugar cane is grown is generally gently sloping. On the large haciendas, when preparing virgin soil for planting, the brush is first cleared away and the holes filled. The ground is then ploughed and cross-ploughed by steam-ploughs and broken fine by clod-crushers; roadways and drainage ditches are laid out, forming squares or rectangles, and furrows are made at intervals of three to four feet. This done, the ground is ready for planting. The cane tops used for seed are cut during harvesting, loaded on cars and sent to the field that is to be planted. The seed cane is placed horizontally in the furrow and covered with a few inches of earth, and as soon as the whole field is planted in this manner, water from the irrigation ditch is turned in and the cane left to grow. The first weeding is done when the cane shoots are a foot high, and it is continued at intervals until the cane leaves become large enough to shade the ground and prevent weed growth. The cane matures in from eighteen to twenty-four months, according to location, soil and weather conditions. Some weeks before harvesting, irrigation is discontinued in order to allow the cane to ripen.

In cultivating the first ratoons, when the cane gets to be a few feet high the crest of the furrow is thrown down into the furrow so that the irrigation water passes between the rows of cane instead of along the furrows, as in the case of plant cane.

Ratooning is kept up until it ceases to be profitable. At the Hacienda Cartavio, four ratoon crops have been grown in some places, and as many as seven in others, with good results.

[Illustration: PLANTING CANE, PERU]

[Illustration: PORTABLE BRANCH LINE OF FIELD RAILWAY AND CANE CUTTERS, PERU]

The principal ingredient of the fertilizer used is guano, which is mixed with lime, nitrate of soda, potassium sulphate, or ashes from the bagasse furnaces, and it is applied in various ways. Some planters throw it in the furrows with the seed cane and allow it to remain there a time before turning on the water; others place it in the furrows a few months after the planting and cover it immediately, while still another method is to apply it and turn on the water at the same time. On certain plantations the fertilizer is ground and spread over the entire field just before replanting.

Water for irrigating is obtained from the mountain streams, which are dammed at certain points, and but little is pumped from wells. The quantity needed is far less than in Hawaii, owing to the nature of the soil and the presence of underground moisture close to the surface. A fixed amount is assigned to each estate by the government and this is never exceeded during the dry season. In flood time, however, the regulations are somewhat relaxed, as there is then enough for all and to spare.

The water is brought on the land by large ditches, and thence to the cane fields through smaller ones. From these field ditches it flows directly into the cane rows at the upper end of the field or section, and, owing to the slight slope of the land, it passes freely through the parallel rows from the upper to the lower end of the section. It is retained in the furrow by means of a dam at the lower end. Other ditches are made at the lower ends of the sections for drainage purposes. The amount of irrigating done varies according to the nature of the land; in some cases water is applied only once during the season, in others as many as twenty-four times. The average number of waterings is five.

When the cane is ripe it is cut by laborers with heavy knives, or machetes, and loaded by hand into cars that run through the fields on portable tracks. These cars, which hold from two to ten tons each, are made up into trains and drawn by a locomotive to the mill. The average yield per acre in 1912 was about 34 tons, but the planters are seeking for better results through improved field methods and new varieties of cane. Pests and disease do little damage in Peru, although the borer gives some trouble. Owing to the long period of growth in a dry climate, Peruvian cane is high in fiber and low in juice, but the juice is rich and very pure; this combination of high fiber content and high percentage of sugar in the juice, however, brings about an unusual loss of sugar in the bagasse.

Nearly all of the sugar manufactured is a coarse-grained centrifugal raw, polarizing about 96.5 degrees and known to the trade as “Peruvian crystals.” Part of it is marketed in the United States and the rest goes to Great Britain, while the second and third sugars are sent to Chile to be refined there. A certain amount of white sugar for home consumption is made by washing the brown centrifugal sugar.

[Illustration: HAULING CANE-LADEN CARS WITH OX-TEAM, PERU]

[Illustration: TRAIN-LOAD OF CANE EN ROUTE TO THE FACTORY, PERU]

At the beginning of the Chilean war the output was approximately 80,000 tons. In 1905 the production of sugar and molasses was 159,294 long tons, and 132,222 tons of this were exported.

The following table gives the outturn in long tons since 1905:

YEAR CONSUMPTION EXPORTS TOTAL

1905 27,077 132,136 159,213 1906 32,178 134,592 166,770 1907 30,110 108,886 138,986 1908 31,895 122,940 154,836 1909 29,173 123,393 152,567 1910 29,189 119,744 148,933 1911 31,988 121,758 153,745 1912 36,129 145,106 181,236 1913 34,976 140,669 175,645 1914 32,555 173,910 206,465 1915 40,000 208,487 248,487

The possibilities for expansion in Peru’s sugar industry are large. Further impounding and conservation of the flood waters from the mountains would bring under cultivation many thousands of acres that are now unproductive. Good flowing wells have been sunk on some estates, and it is likely that many more will be found, thus adding substantially to the present water supply. As to cost, it would seem that Peru should be able to compete successfully with other cane-growing countries. The plantation lands are level or slightly sloping, so that cultivating machinery may be used to good advantage. Grinding can be carried on without interruption throughout the year, which means economical factory capacity and an even distribution of labor. The cost of labor, too, is reasonable, and great quantities of fertilizers lie close at hand. In short, Peru enjoys many advantages, and if her planters and refiners keep pace with scientific development, she will take a prominent place among the cane-sugar countries of the world.

BRAZIL

Brazil is the largest political division of South America. Its area is 3,270,000 square miles, or slightly greater than that of the United States, excluding Alaska. From Cape Orange, in 4 degrees 21 minutes north latitude, it extends 2629 miles southward to the river Chuy, in 33 degrees 45 minutes south latitude, and from Olinda 2691 miles west to the Peruvian border, between 34 degrees 50 minutes and 73 degrees 50 minutes west longitude. According to the latest census returns at hand, the population numbers 20,515,000.

Speaking generally, Brazil is a tropical country with sub-tropical and temperate regions in the south and in a large part of the high central plateau. The sugar-producing states are Maranhão, Rio Grande do Norte, Parahyba, Pernambuco, Alagoas, Sergipe, Bahia, Minas Geraes, Rio de Janeiro and São Paulo. The plantations themselves lie between 4 degrees and 21 degrees south latitude, and being swept by the moisture-laden eastern trade winds, they receive a fair amount of rain during the wet season, that

is, from January to May.

Traces of a vanished civilization had already given rise to the belief that the history of Brazil, like that of Mexico and Peru, extended far into remote ages, when, in 1845, the discovery in the interior of the country of the ruins of a large and very ancient city, with magnificent buildings bearing inscriptions in unknown characters, confirmed this opinion.

Nevertheless, the known history of Brazil dates only from the end of the fifteenth century. It was discovered in February, 1499, by Vicente Yañez Pinzon, a companion of Columbus. The following year it was annexed to Portugal by Pedro Alvares Cabral, but the new territory received little attention from the Portuguese monarchs until 1531, when an attempt at colonization was made. Shortly afterward a sugar mill was erected in São Vicente Piratininga, now São Paulo, and as the soil and climate of that part of the country were well adapted to cane culture, the industry grew and other factories were built. In 1580 there were 120 mills, the greater number being in Bahia and Pernambuco. That same year Philip II of Spain usurped the crown of Portugal, and Brazil, with the rest of the Portuguese possessions, came under Spanish rule. Under the new régime she was exposed to attack by powerful foes. Dutch forces occupied Bahia in 1624, only to be expelled by the Spaniards a year later; in 1629, however, they obtained a foothold in Pernambuco. They took Olinda and its port, but were unable to extend their influence beyond the borders of the town until the arrival of the newly appointed governor, Count John Maurice of Nassau-Siegen, in 1636. This able executive carried the Dutch dominion along the coast from the mouth of the São Francisco to Maranhão, and an expedition sent out by him captured Angola and São Thomé on the west African coast, thus securing a supply of negro slaves, while depriving the enemy of them. He did much to build up the sugar industry, so severely crippled by the war, and when in 1644 he resigned his post, the importance of Brazil as a sugar-producing country had been re-established. The Portuguese threw off the yoke of Spain in 1640 and immediately set about to retake their former colony, Brazil. After years of fighting, the Dutch were finally overcome and in 1655 a government decree drove them from the country. This banishment deprived Brazil of the Dutch sugar planters, with their slaves, their capital, their practical knowledge and skill. From the time of their exodus the Brazilian sugar industry began to decline. The greater number of these refugees established themselves in the West Indies, where they again engaged in sugar planting with marked success.

Brazil became an independent power in 1825 as an empire, with Dom Pedro I, son of the Portuguese king, on the throne. This monarch abdicated in 1831 in favor of the five-year-old heir apparent, who took the name of Dom Pedro II and reigned until 1889, when the empire gave way to a republic. The wars carried on by Brazil against her neighbors between 1851 and 1870 brought her provinces into touch with each other, as well as with the outside world.

In 1826 she pledged herself to Great Britain that, beginning with 1830, she would suppress the traffic in African negro slaves. This promise, however, she failed to keep, so the British parliament passed an act directing the seizure of all slave ships found in Brazilian waters. In every instance the slaves were liberated and the slave dealers brought before British tribunals. Complete suppression of the importation of slaves was the result. In 1871 children born of slave parents were declared free by law, and the movement in favor of emancipation continued until 1888, when slavery was entirely abolished without any indemnity to the slave owners.

The long reign of Dom Pedro II was marked by progress and prosperity. The emperor had the best interests of his people always at heart and concerned himself more with economic development than with political activities. Broad and liberal in his views, he made no attempt to prevent the spread of socialistic doctrines, which, about the year 1880, began to seriously affect the thought of the educated classes. The feeling of unrest and the desire for change engendered in this way culminated in the military conspiracy of 1889, and, as was only natural, the former slave owners, smarting under their losses, took sides against the emperor. The monarchy fell and was replaced by a republican form of government, which, despite several attempts to restore the empire, has endured to the present day.

In the sugar-growing regions of the north and center methods of cultivation do not show much improvement over the practice of early times. Cane is planted in holes about nine inches deep and five feet apart, no fertilizer being used. Some five weeks later the soil is turned up and after fifteen months' growth the cane matures. In São Paulo, however, the planters work on more scientific lines, and ploughing, furrowing, tilling, fertilizing and weeding are done in a thorough manner. The crop depends upon rainfall entirely, and in a normal season ripens in from fourteen to sixteen months. As soon as the cane is cut the dry cane leaves are burned and ploughing begins. The plough passes close enough to the cane roots to tear them more or less, thus helping the new growth. Shortly after the new cane shoots appear, the ground is spaded up or ploughed, just as in the case of plant cane. Ratoons ripen in twelve or fourteen months, and as a rule four to six ratoon crops are grown before replanting is done.

The yield of cane varies with the rainfall and the richness of the soil, and ranges from 20 to 30 tons per acre for first ratoons, diminishing with succeeding crops. The sugar content frequently reaches 18 per cent.

Cane is grown either by colonos or by indentured laborers. In the colono system a tract of land from 9 to 36 acres in size and planted to cane is assigned by the estate to a group of colonos according to their number. The colonos care for the cane during its period of growth and harvest it when ripe. For this they receive the equivalent of $12.50 American gold per acre. Assuming that the yield per acre is 20 tons, the cost to the owner of the estate of cultivating and harvesting a ton of cane is 62½ cents. The colono is given pasture land for his cattle, fuel and house rent free.

The indentured laborers are allotted a certain amount of untilled ground, which they prepare, plant and cultivate. Seed cane, houses and pasturage are furnished gratis, and when the cane is ripe they harvest it. The amount paid the indentured laborers for cane raised in this way fluctuates according to the market value of sugar. For example, in São Paulo when the price of sugar is $4.41 gold per hundredweight, the laborer gets $2.23 per ton for his cane; when the price exceeds $4.41 and is less than $5.90 per hundredweight, he receives $2.55 per ton; when sugar sells between $5.90 and $8.60 per hundredweight, his share is $3.18 per ton; should the price go over $8.60, he gets $3.82 per ton.

The practice in Bahia is somewhat different. Taking as a basis a price of $2.939 gold per hundredweight for sugar, the cane brings $1.646 per long ton, and for every .147 cent (■ cent) per pound fluctuation in the price of sugar, the value of cane changes 9.88 cents per ton up or down as the case may be.[75]

In the small factories the methods of manufacture are very old-fashioned. The cane is crushed between rolls of hard wood, and the juice, after being strained to remove the suspended impurities, is boiled to grain in copper kettles. The magma is then run into large wooden moulds having cone-shaped, perforated bottoms. The holes in the bottom of these moulds are closed when the hot massecuite is dumped in, but as soon as it cools the plugs are taken out and the molasses allowed to drain off. A layer of very wet clay is then spread over the top of the sugar, and as the water slowly drains from the clay it passes through the sugar crystals, carrying the mother liquor with it. After this washing process has gone on for some time, the sugar is removed from the moulds, and the upper portion is found to be white, or nearly so, while underneath the color deepens into yellow and from that to brown as the bottom is reached. The sugars are carefully separated according to their color, then dried and packed in bags containing 60 kilograms or about 132 pounds each.

[Illustration: SUGAR PLANTATION BETWEEN RIO DE JANEIRO AND SÃO PAULO, BRAZIL]

It will readily be seen that the loss in extraction by such means is very great. In fact, from cane having a sugar content of 15 per cent, sometimes not more than between 5 per cent and 6 per cent of sugar is recovered. The best results are naturally obtained in the large factories, or usines, but even there, owing to poor crushing, 9 per cent of the weight of the cane in sugar is considered satisfactory.

In the usines the juices are treated with sulphur and neutralized with lime. They are then allowed to settle, after which they are boiled to grain and the crystals separated from the mother liquor in centrifugal machines. The sugar is dried and the remaining liquor is returned to the pans for reboiling.

The various grades produced are:

Cristaes blancos (white washed sugar) Cristaes amarellos (first yellow, termed Demerara) Mascavinhos (second yellow, fine grain) Mascavos (dark brown sugar, final product)

The greater portion of the sugars made in Brazil is refined, but a certain amount goes directly into consumption in its raw state. Refining on a large scale according to European methods has been tried at various times, but, owing to the high cost of labor, fuel and transportation, all these attempts have proved unsuccessful. Then again, the demand for sugar prepared in the European way is not great, the Brazilians preferring the moist fine-grained sugar made in the small refineries. This sugar has a molasses taste, polarizes about 91 degrees and carries about 2 per cent of glucose. In manufacturing the white grade, a liquor of 31 degrees Baumé[76] is first made from raw sugar. This is clarified with ox-blood and filtered through bone-char, after which the clear liquor is boiled at a temperature of 266 degrees Fahrenheit over an open fire until only about 4 per cent of water remains. It is then removed from the fire, a small quantity of dry granulated sugar is added and the mass is stirred with a wooden paddle. Cool, dry, fine-grained sugar is the result. The yellow grade, or _terzira_, as it is called, is made in exactly the same manner, except that no clarifying or filtering is done. The rich molasses odor and taste of this sugar please the popular palate to such an extent that it commands a

higher price than white granulated sugar refined by the most modern processes. In fact nearly 75 per cent of the sugar consumed in Rio de Janeiro is terzira. Its manufacture does not require expensive equipment or any great amount of technical skill, hence it appeals to the native merchants and confectioners.

Recently the government has put forth some effort to encourage and improve the sugar industry, but so far without much success. A law was passed in 1875 guaranteeing a return of 7 per cent upon the money expended in constructing central factories, a given number being allowed each state. This act was modified some years later and the rate of interest reduced to 6 per cent, but as the refunding period was longer it met with more favor than the first and a number of concessions were granted. In 1889 the state of Pernambuco appropriated a sum equal to $135,000.00 gold to be divided among forty factories, with the understanding that repayment was to be begun after the harvesting of the third crop and extended over a period of twenty years. All this legislation had no definite result.

A few years ago, a combination of the producers was formed for the purpose of maintaining a high price for domestic sugar by setting aside a certain fixed amount for export. At first this was 20 per cent, but it was afterward increased to 40 per cent. The plan, however, was ineffectual. A heavy import duty (about 5.86 cents per pound) prohibits the bringing in of foreign sugars, so that Brazil must provide for her requirements within her own borders.

Accurate information concerning production, distribution and prices is hard to obtain. Bad transportation facilities, diversity of customs regulations between the states, and the vast number of small producers who sell to the consumer direct, make the compilation of dependable data almost an impossibility. The statistics that are submitted, therefore, are approximative.

Brazil's sugar exports grow less and less. The United States no longer depends upon her for supplies, so that the outlook for the industry in Brazil is not bright at the present time. Modern refining methods are not regarded with favor by the people and any considerable extension in production seems remote.

PRODUCTION IN BRAZIL

BRITISH GUIANA

Guiana, in its widest meaning, is the name given to that part of South America that lies between 8 degrees 40 minutes north and 3 degrees 30 minutes south latitude and 50 degrees and 68 degrees 30 minutes west longitude. This vast territory, about 690,000 square miles in area, comprises Venezuelan Guiana, British Guiana, Dutch Guiana (Surinam), French Guiana (Cayenne), and Brazilian Guiana. The first of these divisions is now part of Venezuela and the last is included in Brazil.

The coast of British Guiana is fringed by low, alluvial flats, the result of deposit by the rivers. Beginning at three feet below high-water mark, these flats extend inland 25 or 30 miles, rising imperceptibly about 15 feet. Beyond is a broad, rolling region of sandy clay formation, 150 feet above sea-level, which runs back to the forest-covered hills. Two ranges of mountains traverse the country from west to east and a third chain forms the southern boundary and the watershed between the Essequibo and the Amazon. The highest mountain peak is Roraima on the western border, 8635 feet.

The rivers of British Guiana and their tributaries form a network of waterways throughout the country and they are practically the only transportation routes from the coast into the interior. The most important are the Essequibo, the Demerara, the Berbice and the Corentyn. The Essequibo has its source in the Acari mountains near the equator at 850 feet above the sea, and it flows north about 600 miles, reaching the Atlantic by an estuary 15 miles wide, in which there are a number of large and fertile islands. At one time sugar cane was grown on four of these islands, but today only one, Wakenaam, has a sugar mill.

For the ten months beginning with October and ending in July, the temperature on the coast is even, as the northeast trade winds keep it down to 80 degrees Fahrenheit on an average, but the cessation of the trades in August and September makes the heat oppressive. Hurricanes are unknown and but little damage is caused in the coast regions by earthquakes, owing to the character of the soil. In the interior the year is divided into one wet and one dry season, but in the low-lying coast country, where the sugar plantations are, there are two wet and two dry periods. The long wet season begins about the middle of April and lasts until August;

the long dry period is from September to the end of November. The rainfall varies greatly according to locality; on the coast the yearly average is 80 inches. In 1914 the population was estimated to be 304,089; of these 120,000 were negroes, 124,000 East Indians, 11,600 Portuguese, 4300 Europeans of other nationalities, 6500 aborigines and over 30,000 of mixed race.

Guiana was sighted by Columbus in 1498 and by Alonzo de Ojeda and Amerigo Vespucci in the year following. Vicente Yañez Pinzon is credited with having sailed up some of the rivers in 1500 and Sir Walter Raleigh ascended the Orinoco in 1595 in quest of the mythical city El Dorado. Dutch traders reached Guiana in 1598 and by 1613 they had established several settlements on the coast of Demerara and Essequibo. Meanwhile English and French adventurers were endeavoring to obtain a foothold in Surinam and Cayenne, which they succeeded in doing in 1652. The colony of Essequibo was under the administration of the Dutch West India company from 1621 until 1791, when the company was dissolved. A Dutch settlement established on the Berbice river in 1624 was the beginning of the colony of that name, which was taken under the protection of the States-general of Holland in 1732. Demerara, formerly a dependency of Essequibo, became a separate colony in 1773. In 1781 the three colonies, Essequibo, Demerara and Berbice, were captured by British privateers. The following year they were taken by France, and restored to Holland in 1783. The British took possession a second time in 1796, retaining them for about six years, at the end of which period they passed back into the hands of Holland once more. The British occupied them in 1803 and they were formally ceded to Great Britain in 1815. The three colonies were consolidated into one under the name of British Guiana in 1831.

Essequibo, Berbice and Demerara all produced a considerable amount of sugar during the Dutch régime. The plantations were on coast and river lands that had been diked and drained. Like all sugar-growing countries, this colony was adversely affected by the abolition of slavery, but owing to the success that attended the introduction of coolies from Hindustan, the labor situation never became so acute as it did in many islands of the West Indies. Traffic in African negro slaves was forbidden in 1808. After 1834 the sugar planters sought free laborers in the neighboring islands and in Madeira. Many people who had been deprived of their means of livelihood by the destruction of the vineyards of Madeira by disease settled in British Guiana. The importation of free negroes from British African possessions was sanctioned by the home government in 1840, and between that year and 1865 a large number of slaves taken by British war ships from Cuban and Brazilian slavers were landed in British Guiana, where they found employment as free laborers. This source of labor supply was cut off by the abolition of slavery in Brazil and other countries. In 1867 the importation of free blacks from British Africa was prohibited and the movement to supply laborers from China came to an end. The Chinese experiment was repeated in 1874 and 1878, but never since. The bringing in of British Indians, however, proved a success ever since the time it was first done in 1838. These laborers are indentured for five years, and five years after the expiration of their contract they have the privilege of being taken back to their homes, without charge. During the five years following their contract term they can obtain work as free hands and they may acquire small parcels of land. In fact many of them have become land owners and have settled permanently in the colony. There are also a considerable number who, after having gone back to India, return to British Guiana of their own volition and at their own expense to work as free laborers.

Most of the sugar plantations are found on the seacoast on lands formerly marshy that have been diked and drained either by sluices or by pumping. The plantations along the river banks, too, are on reclaimed lands that have been drained by sluices. In 1911 there were 160,000 acres of reclaimed land in the colony, and 81,000 acres of it were devoted to sugar cane. The plantations are oblong in shape, one end fronting on the sea or the river, as the case may be. Originally they varied in size from 500 to 1000 acres, but in many instances consolidation has taken place. The dike next to the sea is naturally the strongest and most carefully built, while those at the sides and rear are less substantial. As a rule, there is a broad road that runs through the middle of the plantation, with a navigable canal on either side. These canals contain fresh water, salt water and flood waters being kept out by a gate through which excess fresh water may run off at low tide. Short feeder canals run at right angles, and as they are not connected with the drainage canals they may contain salt water if necessary. In crossing a transportation canal, the waters of drainage canals pass underneath through a siphon. Between these transportation canals are the cane fields, from ten to twenty acres in size, and separated from one another by small drainage ditches. The largest transportation canals are between sixteen and twenty feet wide at the top, between twelve and sixteen feet wide at the bottom and four to five feet deep. The smaller transportation canals are twelve feet wide at the top, nine feet wide at the bottom and four to five feet deep. The large drainage canals are fifteen feet wide and four feet deep, and the irrigation ditches are from two to three feet wide and three feet deep.

Before planting cane in virgin soil the trees are cut down, the ground is cleared of grass and weeds, canals are dug, furrows are made at intervals of from six to seven feet, and then the planting is done. A month later weeds are removed, the young shoots are banked and the ground between the furrows is loosened. When five months old the cane is trashed[77] and weeding is done if necessary. After an interval of three months this operation is repeated, and when the cane is a year old the final trashing is done,

the harvesting following two weeks afterward.

When the cane has been cut, the ground is loosened once more, the dry leaves are put in the spaces between the furrows and covered with earth, the young cane shoots come up, and in another year the ratoons are ready for harvesting. Two or three ratoon crops are grown on the same land, but as soon as the yield gets too small the ground is left fallow and planting is done elsewhere. Until recently Bourbon cane was the only variety raised in British Guiana. Of late, however, many kinds of seedling cane have been introduced, and today it is estimated that more than one-half of the crop comes from seedling stock. Fertilizing is done with phosphates, guano, potash, sulphate of ammonia and stable manure.

The cane is brought from the fields to the mills by canal in flat-bottomed boats. The equipment in the factories is good, as a whole; crushing is efficiently done and the juices are boiled to grain in vacuum pans.

In addition to 96-degree centrifugals and second sugars, the celebrated “Demerara crystals” are produced. In making the latter the juice is kept acid throughout the process, from one to five per cent being lost through inversion. Chloride of tin is added in the vacuum pan to heighten the yellow color. The greater part of the molasses goes into the manufacture of rum, and a certain quantity, mixed with ground bagasse, finds a market in England as cattle food.

While on virgin soil the yield of cane runs as high as sixty to seventy tons to the acre, the average is about twenty tons per acre, and the extraction of sugar equals 8½ per cent of the weight of the cane. In late years the number of sugar mills has grown less, owing to the merging of many small plants into a few large ones. In 1908 the area planted in cane was 73,471 acres, and there were forty-two plantations, six of them less than 1000 acres, twenty-five over 1000 acres, six over 2000 acres, four over 3000 acres, and one over 7000 acres in size.

Over half of the sugar exported goes to Canada, the remainder being taken by Great Britain and the United States.

As to the future of British Guiana’s sugar industry, early in 1915 a letter was sent by the government secretary of the colony to the West India committee in London in which it is stated that the possible annual crop on suitable sugar lands eastward of the Pomeroon river is not less than 1,000,000 tons, while, if the large virgin alluvial areas to the east of the Pomeroon river and between there and the Venezuelan boundary were brought under cultivation, the maximum total output might reach 2,500,000 tons per annum. This letter was in reply to a communication addressed by the West India committee to the governors of all of the British sugar-growing possessions for the purpose of securing information regarding the possibilities of development of the industry. Hitherto the United Kingdom has been largely dependent upon foreign countries for its sugar supply, and the movement thus set on foot by the West India committee is to urge upon the home government the importance of drawing the entire sugar requirements of the country from its colonies. This of course would mean the establishment of a preferential tariff.

Exports from British Guiana since 1895, in tons of 2240 pounds:

ARGENTINA

The Argentine republic occupies the southeastern extremity of South they would still have done the same thing, for our experiences had taught us to dispense with fear. Whatever of timidity, of shrinking from pain or hardship any of us had originally possessed, it had all vanished. There were no terrors that we were not now ready to face.

The year 1909 marks an important point in our struggle, partly because of this decision of ours, never again to submit to be classed with criminals; and partly because in this year we forced the Liberal Government to go on record, publicly, in regard to the oldest of popular rights, the right of petition. We had long contemplated this step, and now the time seemed ripe for taking it.

In the closing days of 1908 Mr. Asquith, speaking on the policy to be carried out in 1909, commented on the various deputations he was obliged at that time to receive. They called on him, he said, "from all quarters and in all causes, on an average of something

like two hours on three days in every week." The deputations all asked for different things, and, although all of the things could not possibly be included in the King's speech, Mr. Asquith was inclined to agree that many of them ought to be included. This declaration from the Prime Minister that he was constantly receiving deputations of men, and listening favourably to their suggestions of what policies to pursue, aroused in the Suffragettes feelings of deep indignation. This in part they expressed on January 25th, when the first meeting of the Cabinet Council took place. A small deputation from the W. S. P. U. proceeded to Downing Street to claim the right to be heard, as men were heard. For knocking at the door of the official residence four of the women, including my sister, Mrs. Clark, were arrested and sent to prison for one month.

A month later the seventh of our Women's Parliaments was called against this and against the fact that no mention of women had been included in the King's speech. Led by Mrs. Pethick Lawrence, Lady Constance Lytton and Miss Daisy Solomon, a deputation of women endeavoured to carry the resolution to the House of Commons. They were promptly arrested and, next day, were sent to prison on sentences of from one to two months. The time was rapidly approaching when the legality of these arrests would have to be tested. In June of the year 1909 the test was made.

It will be remembered that we had endeavoured to force the authorities to make good their threat to charge us under the obsolete Charles II "Tumultuous Petitions Act," which prescribes severe penalties for persons proceeding to Parliament in groups of more than twelve for the purpose of presenting petitions. It had been stated that if we were charged under that act our case would be given a hearing before a judge and jury instead of a police magistrate. Since this was exactly what we desired to have happen we had sent deputation after deputation of more than twelve persons, but always they were tried in police courts, and were sent to prison often for periods as long as that prescribed in the Charles II Act. Now we determined to do something still more ambitious; we resolved to test, not the Charles II Act, but the constitutional right of the subject to petition the Prime Minister as the seat of power.

The right of petition, which has existed in England since the earliest known period, was written into the Bill of Rights which became law in 1689 on the accession of William and Mary. It was, in fact, one of the conditions attaching to the accession of the joint monarchs. According to the Bill of Rights, "It is the right of subjects to petition the King and all commitments, and prosecutions for such petitionings are illegal." The power of the King having passed almost completely into the hands of Parliament, the Prime Minister now stands where the King's majesty stood in former times. Clearly, then, the right of the subject to petition the Prime Minister cannot be legally denied. Thus were we advised, and in order to keep within the strict letter of the law, we accepted the limitations of the right of petition laid down in the Charles II Act, and decided that our petition should be carried to the House of Commons by small groups of women.

Again I called together, on the evening of June 29th, a Parliament of women. Previously I had written to Mr. Asquith stating that a deputation of women would wait on him at the House of Commons at eight o'clock in the evening. I wrote him further that we were not to be refused, as we insisted upon our constitutional right to be received. To my note the Prime Minister returned a formal note declining to receive us. Nevertheless we continued our preparations, because we knew that the Prime Minister would continue to decline, but that in the end he would be forced to receive us.

An incident which occurred a week before the date of the deputation was destined to have important consequences. Miss Wallace Dunlop went to St. Stephen's Hall in the House of Commons, and marked with printer's ink on the stone work of the Hall an extract from the Bill of Rights. The first time she made the attempt she was interrupted by a policeman, but two days later she succeeded in stamping on the ancient walls the reminder to Parliament that women as well as men possess constitutional rights, and that they were proposing to exercise those rights. She was arrested and sentenced to prison for one month, in the third division. The option of a heavy fine was given her, which of course she refused. Miss Wallace Dunlop's prison term began on June 22d. Perhaps her deed had something to do with the unusual interest taken in the approaching deputation, an interest which was shown not only by the public but by many members of Parliament. In the House of Commons a strong feeling that the women ought this time to be received manifested itself in many questions put to the Government. One member even asked leave to move the adjournment of the House on a matter of urgent public importance, namely the danger to the public peace, owing to the refusal of the Prime Minister to receive the deputation. This was denied, however, and the Government mendaciously disclaimed all responsibility for what action the police might take toward the deputation. The Home Secretary, Mr. Gladstone, when asked by Mr. Kier Hardie to give instructions that the deputation, if orderly, should be admitted to St. Stephen's, replied: "I cannot say what action the police ought to take in the matter." Our Women's Parliament met at half past seven on the evening of June 29th, and the petition to the Prime Minister was read and adopted. Then our deputation set forth. Accompanying me as leader were two highly respectable women of advanced years, Mrs. Saul Solomon, whose husband had been Prime Minister at the Cape, and Miss Neligan, one of the

foremost of the pioneer educators of England. We three and five other women were preceded by Miss Elsie Howey, who, riding fast, went on horse-back to announce our coming to the enormous crowds that filled the streets. She, we afterward learned, progressed as far as the approaches to the House of Commons before being turned back by the police. As for the deputation, it pressed on through the crowd as far as St. Margaret's Church, Westminster, where we found a long line of police blocking the road. We paused for a moment, gathering strength for the ordeal of trying to push through the lines, when an unexpected thing happened. An order was given from some one, and instantly the police lines parted, leaving a clear space through which we walked towards the House. We were escorted on our way by Inspector Wells, and as we passed the crowd broke into vociferous cheering, firmly believing that we were after all to be received. As for myself I did little speculating as to what was about to happen. I simply led my deputation on as far as the entrance to St. Stephen's Hall. There we encountered another strong force of police commanded by our old acquaintance, Inspector Scantlebury, who stepped forward and handed me a letter. I opened it and read in aloud to the women. "The Prime Minister, for the reasons which he has already given in a written reply to their request, regrets that he is unable to receive the proposed deputation."

I dropped the note to the ground and said: "I stand upon my rights, as a subject of the King, to petition the Prime Minister, and I am firmly resolved to stand here until I am received."

[Illustration: INSPECTOR WELLS CONDUCTING MRS. PANKHURST TO THE HOUSE OF COMMONS

June, 1908]

Inspector Scantlebury turned away and walked rapidly towards the door of the Strangers' Entrance. I turned to Inspector Jarvis, who remained, to several members of Parliament and some newspaper men who stood looking on, and begged them to take my message to the Prime Minister, but no one responded, and the Inspector, seizing my arm, began to push me away. I now knew that the deputation would not be received and that the old miserable business of refusing to leave, of being forced backward, and returning again and again until arrested, would have to be re-enacted. I had to take into account that I was accompanied by two fragile old ladies, who, brave as they were to be there at all, could not possibly endure what I knew must follow. I quickly decided that I should have to force an immediate arrest, so I committed an act of technical assault on the person of Inspector Jarvis, striking him very lightly on the cheek. He said instantly, "I understand why you did that," and I supposed then that we would instantly be taken. But the other police apparently did not grasp the situation, for they began pushing and jostling our women. I said to the inspector: "Shall I have to do it again?" and he said "Yes." So I struck him lightly a second time, and then he ordered the police to make the arrests.

The matter did not end with the arrest of our deputation of eight women. In recurring deputations of twelve the Suffragettes again and again pressed forward in vain endeavour to reach the House of Commons. In spite of the fact that the crowds were friendly and did everything they could to aid the women, their deputations were broken up by the police and many of the women arrested. By nine o'clock Parliament Square was empty, an enormous force of mounted police having beaten the people back into Victoria Street and across Westminster Bridge. For a short time all looked tranquil, but soon little groups of women, seven or eight at a time, kept appearing mysteriously and making spirited dashes toward the House. This extraordinary procedure greatly exasperated the police, who could not unravel the mystery of where the women came from. As a matter of bygone history the explanation is that the W. S. P. U. had hired thirty offices in the neighborhood, in the shelter of which the women waited until it was time for them to sally forth. It was a striking demonstration of the ingenuity of women opposing the physical force of men, but it served still another purpose. It diverted the attention of the police from another demonstration which was going on. Other Suffragettes had gone to the official residence of the First Lord of the Admiralty, to the Home Office, the Treasury and Privy Council Offices, and had registered their contempt for the Government's refusal to receive the deputation by the time-honoured method of breaking a window in each place.

One hundred and eight women were arrested that night, but instead of submitting to arrests and trial, the Women's Social and Political Union announced that they were prepared to prove that the Government and not the women had broken the law in refusing to receive the petition. My case, coupled with that of the Hon. Mrs. Haverfield, was selected as a test case for all the others, and Lord Robert Cecil was retained for the defence. Mr. Muskett, who conducted the case for the prosecution, tried to prove that our women had not gone to the House of Commons to present a petition, but this was easily demonstrated to be an unwarranted claim. The speeches of the leader, the official articles published in our newspaper, _Votes for Women_, and the letters sent to Mr. Asquith, not to speak of the indisputable facts that every member of the deputation carried a copy of the petition in her hand, furnished evidence enough of the nature of our errand. The whole case of the subject's right of petition was then brought forward

for discussion. Mr. Muskett spoke first, then our council, Mr. Henle, then Lord Robert Cecil. Last of all I spoke, describing the events of June 29th. I told the magistrate that should he decide that we and not the Government had been guilty of an infraction of the law, we should refuse to be bound over, but should all choose to go to prison. In that case we should not submit to being treated like criminals. "There are one hundred and eight of us here to-day," I said, pointing to the benches where my fellow-prisoners sat, "and just as we have thought it is our duty to defy the police in the street, so when we get into prison, as we are political prisoners, we shall do our best to bring back into the twentieth century the treatment of political prisoners which was thought right in the case of William Cobbett, and other political offenders of his time."

The magistrate, Sir Albert de Rutzen, an elderly, amiable man, rather bewildered by this unprecedented situation, then gave his decision. He agreed with Mr. Henle and Lord Robert Cecil that the right of petition was clearly guaranteed to every subject, but he thought that when the women were refused permission to enter the House of Commons, and when Mr. Asquith had said that he would not receive them, the women acted wrongly to persist in their demands. He should, therefore, fine them five pounds each, or sentence them to prison for one month in the second division. The sentence would be suspended for the present until learned counsel could obtain a decision from a higher court on the legal point of the right of petition.

I then put in a claim for all the prisoners, and asked that all their cases might be held over until the test case was decided, and this was agreed to, except in regard to fourteen women charged with window-breaking. They were tried separately and sent to prison on sentences varying from six weeks to two months. Of them later.

The appeal against Sir Albert de Rutzen's decision was tried in a Divisional Court early in December of that year. Lord Robert Cecil again appeared for the defence, and in a masterly piece of argumentation, contended that in England there was and always had been the right of petition, and that the right had always been considered a necessary condition of a free country and a civilised Government. The right of petition, he pointed out, had three characteristics: In the first place, it was the right to petition the actual repositories of power; in the second place, it was the right to petition in person; and in the third place, the right must be exercised reasonably. A long list of historical precedents were offered in support of the right to petition in person, but Lord Robert argued that even if these did not exist, the right was admitted in the Charles II "Tumultuous Petitions Act," which provides "That no person or persons whatsoever shall repair to His Majesty or both or either Houses of Parliament upon pretence of presenting or delivering any petition, complaint, remonstrance, or declaration or other address, accompanied with excessive number of people ..." etc. The Bill of Rights had specially confirmed the right of petition in so far as the King personally was concerned. "The women," pursued Lord Robert, "had gone to Parliament Square on June 29th in the exercise of a plain constitutional right, and that in going there with a petition they had acted according to the only constitutional method they possessed, being voteless, for the redress of their grievances."

If then it were true, as contended, the subject not only possessed the right to petition, but to petition in person, the only point to be considered was whether the right had been exercised reasonably. If persons desired to interview the Prime Minister, it was surely reasonable to go to the House of Commons, and to present themselves at the Strangers' Entrance. Mrs. Pankhurst, Mrs. Haverfield and the others had, as the evidence showed, proceeded along the public highway and had been escorted to the door of the House of Commons by an officer of the police, and could not therefore, up to that point, have been acting in an unlawful manner. The police had kept clear a large open space opposite the House of Commons, the crowd being kept at a certain distance away. Within the open space there were only persons having business in the House of Commons, members of the police force and the eight women who formed the deputation. It could not possibly be contended that these eight women had caused an obstruction. It was true that a police officer told them that the Prime Minister was not in the House of Commons, but when one desired an interview with a Member of Parliament one did not make his request of a casual policeman in the street. Moreover, the police did not possess any authority to stop anyone from going into the House of Commons.

The letter given the women, in which the Prime Minister said that he could not or would not see them, had been cited. Now, had the Prime Minister, in his letter, said that he could not or would not see the women at that time, that the time was not convenient; but that he would at some future time, at a more convenient time, receive them, that would have been a sufficient answer. The women would not have been justified in refusing to accept such an answer, because the right to petition must be exercised reasonably. But the letter contained an unqualified refusal, and that, if we allow the right of petition to exist, was no answer at all. Last of all Lord Robert argued that if there is a right to petition a Member of Parliament, then it must be incumbent on the part of a Member of Parliament to receive the petition, and that no one has a right to interfere with the petitioner. If the eight women were legally justified in presenting their petition, then they were also justified in refusing to obey the orders of the police to leave the place.

In an address full of bias, and revealing plainly that he had no accurate knowledge of any of the events that had led up to the case in hand, the Lord Chief Justice delivered judgment. He said that he entirely agreed with Lord Robert Cecil as to the right to present a petition to the Prime Minister, either as Prime Minister or as a Member of Parliament; and he agreed also that petitions to the King should be presented to the Prime Minister. But the claim of the women, he said, was not merely to present a petition, but to be received in a deputation. He did not think it likely that Mr. Asquith would have refused to receive a petition from the women, but his refusal to receive the deputation was not unnatural, "in consequence of what we know did happen on previous occasions."[1]

Referring to the Metropolitan Police Act of 1839, which provides that it shall be lawful for the Commissioner of Police to make regulations and to give instructions to the constable for keeping order, and for preventing any obstruction of thoroughfares in the immediate neighbourhood of the House of Commons, and the Sessional Order empowering the police to keep clear the approaches to the House of Commons, the Lord Chief Justice decided that I and the other women were guilty of an infraction of the law when we insisted on a right to enter the House of Commons. The Lord Chief Justice therefore ruled that our conviction in the lower court had been proper, and our appeal was dismissed with costs.

Thus was destroyed in England the ancient constitutional right of petition, secured to the people by the Bill of Rights, and cherished by uncounted generations of Englishmen. I say the right was destroyed, for of how much value is a petition which cannot be presented in person? The decision of the high court was appalling to the members of the W. S. P. U., as it closed the last approach, by constitutional means, to our enfranchisement. Far from discouraging or disheartening us, it simply spurred us on to new and more aggressive forms of militancy.

FOOTNOTE:

[1] Mr. Asquith had never, since becoming Prime Minister, received a deputation of women, nor had he ever received a deputation of the W. S. P. U. So it was absurd of the Lord Chief Justice to speak of "what did happen, on previous occasions."

CHAPTER V

Between the time of the arrest in June and the handing down of the absurd decision of the Lord Chief Justice that although we, as subjects, possessed the right of petition, yet we had committed an offence in exercising that right, nearly six months had passed. In that interval certain grave developments had lifted the militant movement onto a new and more heroic plane. It will be remembered that a week before our deputation to test the Charles II Act, Miss Wallace Dunlop had been sent to prison for one month for stamping an extract from the Bill of Rights on the stone walls of St. Stephen's Hall. On arriving at Holloway on Friday evening, July 2nd, she sent for the Governor and demanded of him that she be treated as a political offender. The Governor replied that he had no power to alter the sentence of the magistrate, whereupon Miss Wallace Dunlop informed him that it was the unalterable resolution of the Suffragettes never again to submit to the prison treatment given to ordinary offenders against the law. Therefore she should, if placed in the second division as a common criminal, refuse to touch food until the Government yielded her point. It is hardly likely that the Government or the prison authorities realised the seriousness of Miss Wallace Dunlop's action, or the heroic mould of the Suffragettes' character. At all events the Home Secretary paid no attention to the letter sent him by the prisoner, in which she explained simply but clearly her motives for her desperate act, and the prison authorities did nothing except seek means of breaking down her resistance. The ordinary prison diet was replaced by the most tempting food, and this instead of being brought to her cell at intervals, was kept there night and day, but always untouched. Several times daily the doctor came to feel her pulse and observe her growing weakness. The doctor, as well as the Governor and the wardresses argued, coaxed and threatened, but without effect. The week passed without any sign of surrender on the part of the prisoner. On Friday the doctor reported that she was rapidly reaching a point at which death might at any time supervene. Hurried conferences were carried on between the prison and the Home Office, and that evening, June 8th, Miss Wallace Dunlop was sent home, having served one-fourth of her sentence, and having ignored completely all the terms of her imprisonment.

On the day of her release the fourteen women who had been convicted of window breaking received their sentences, and learning of Miss Wallace Dunlop's act, they, as they were being taken to Holloway in the prison van, held a consultation and agreed to follow her example. Arrived at Holloway they at once informed the officials that they would not give up any of their belongings, neither would they put on prison clothing, perform prison labour, eat prison food or keep the rule of silence.

The Governor agreed for the moment to allow them to retain their property and to wear their own clothing, but he told them that they had committed an act of mutiny and that he would have to so charge them at the next visit of the magistrates. The women then

addressed petitions to the Home Secretary, demanding that they be given the prison treatment universally allowed political offenders. They decided to postpone the hunger strike until the Home Secretary had had time to reply. Meanwhile, after a vain appeal for more fresh air, for the weather was stiflingly hot, the women committed one more act of mutiny, they broke the windows of their cells.

We learned this from the prisoners themselves. Several days after they had gone to prison, my daughter Christabel and Mrs. Tuke, filled with anxiety for their fate, gained admission to an upper story room of a house overlooking the prison. Calling at the top of their voices and waving a flag of the Union, they succeeded in attracting the prisoners' attention. The women thrust their arms through the broken panes, waving handkerchiefs, Votes for Women badges, anything they could get hold of, and in a few shouted words told their tale. That same day the visiting magistrates arrived, and the mutineers were sentenced to terms of seven to ten days of solitary confinement in the punishment cells. In these frightful cells, dark, unclean, dripping with moisture, the prisoners resolutely hunger struck. At the end of five days one of the women was reduced to such a condition that the Home Secretary ordered her released. The next day several more were released, and before the end of the week the last of the fourteen had gained their liberty.

The affair excited the greatest sympathy all over England, sympathy which Mr. Gladstone tried to divert by charging two of the prisoners with kicking and biting the wardresses. In spite of their vigorous denials these two women were sentenced, on these charges, one to ten days and the other to a month in prison. Although still very weak from the previous hunger strike, they at once entered upon a second hunger strike, and in three days had to be released.

After this each succeeding batch of Suffragette prisoners, unless otherwise directed, followed the example of these heroic rebels. The prison officials, seeing their authority vanish, were panic stricken. Holloway and other women's prisons throughout the Kingdom became perfect dens of violence and brutality. Hear the account given by Lucy Burns of her experience:

"We remained quite still when ordered to undress, and when they told us to proceed to our cells we linked arms and stood with our backs to the wall. The Governor blew his whistle and a great crowd of wardresses appeared, falling upon us, forcing us apart and dragging us towards the cells. I think I had twelve wardresses for my share, and among them they managed to trip me so that I fell helplessly to the floor. One of the wardresses grasped me by my hair, wound the long braid around her wrist and literally dragged me along the ground. In the cell they fairly ripped the clothing from my back, forcing on me one coarse cotton garment and throwing others on the bed for me to put on myself. Left alone exhausted by the dreadful experience I lay for a time gasping and shivering on the floor. By and by a wardress came to the door and threw me a blanket. This I wrapped around me, for I was chilled to the bone by this time. The single cotton garment and the rough blanket were all the clothes I wore during my stay in prison. Most of the prisoners refused everything but the blanket. According to agreement we all broke our windows and were immediately dragged off to the punishment cells. There we hunger struck, and after enduring great misery for nearly a week, we were one by one released."

How simply they tell it. "After enduring great misery--" But no one who has not gone through the awful experience of the hunger strike can have any idea of how great that misery is. In an ordinary cell it is great enough. In the unspeakable squalor of the punishment cells it is worse. The actual hunger pangs last only about twenty-four hours with most prisoners. I generally suffer most on the second day. After that there is no very desperate craving for food. Weakness and mental depression take its place. Great disturbances of digestion divert the desire for food to a longing for relief from pain. Often there is intense headache, with fits of dizziness, or slight delirium. Complete exhaustion and a feeling of isolation from earth mark the final stages of the ordeal. Recovery is often protracted, and entire recovery of normal health is sometimes discouragingly slow.

The first hunger strike occurred in early July. In the two months that followed scores of women adopted the same form of protest against a Government who would not recognise the political character of their offences. In some cases the hunger strikers were treated with unexampled cruelty. Delicate women were sentenced, not only to solitary confinement, but to wear handcuffs for twenty-four hours at a stretch. One woman on refusing prison clothes was put into a straightwaistcoat.

The irony of all this appears the greater when it is considered that, at this precise time, the leaders of the Liberal Party in the House of Commons were in the midst of their first campaign against the veto power of the Lords.

On September 17th a great meeting was held in Birmingham, on which occasion Mr. Asquith was to throw down his challenge to the Lords, and to announce that their veto was to be abolished, leaving the people's will paramount in England. Of course the Suffragettes seized this opportunity for a demonstration. This course was perfectly logical. Denied the right of petition, shut out now from every Cabinet Minister's meeting, the women were forced to take whatever means that remained to urge their cause upon the

Government. Mrs. Mary Leigh and a group of Birmingham members addressed a warning to the public not to attend Mr. Asquith's meeting as disturbances were likely to happen. From the time that the Prime Minister and his Cabinet left the House of Commons until the train drew in to the station at Birmingham they were completely surrounded with detectives and policemen. The precautions taken to guard Mr. Asquith have never been equalled except in the case of the Tsar during outbreaks of revolution in Russia. From the station he was taken by an underground passage a quarter of a mile in length to his hotel, where he dined in solitary state, after having been carried upstairs in a luggage lift. Escorted to the Bingley Hall by a strong guard of mounted police, he was so fearful of encountering the Suffragettes that he entered by a side door. The hall was guarded as for a siege. Over the glass roof a thick tarpaulin had been stretched. Tall ladders were placed on either side of the building, and firemen's hose were laid in readiness--not to extinguish fires, but to play upon the Suffragettes should they appear at an inaccessible spot on the roof. The streets on every hand were barricaded, and police, in regiments, were drawn up to defend the barricades against the onslaughts of the women. Nobody was allowed to pass the barricades without showing his entrance tickets to long files of police, and then the ticket holders were squeezed through the narrow doors one by one.

Their precautions were in vain, for the determined Suffragettes found more than one way in which to turn Mr. Asquith's triumph into a fiasco. Although no women gained access to the hall, there were plenty of men sympathisers present, and before the meeting had proceeded far thirteen men had been violently thrown out for reminding the Prime Minister that "the people" whose right to govern he was professing to uphold, included women as well as men. Outside, mingling in the vast crowds, bands of women attacked the barricades, the outer barricades being thrown down in spite of the thousands of police. From the roof of a neighbouring house Mrs. Leigh and Charlotte Marsh tore up dozens of slates and threw them on the roof of Bingley Hall and in the streets below, taking care, however, to strike no one. As Mr. Asquith drove away the women hurled slates at the guarded motor car. The fire hose was brought forth and the firemen were ordered to turn the water on the women. They refused, to their credit be it said, but the police, infuriated by their failure to keep the peace, did not scruple to play the cold water on the women as they crouched and clung to the dangerous slope of the roof. Roughs in the streets flung bricks at them, drawing blood. Eventually the women were dragged down by the police and in their dripping garments marched through the streets to the police station.

The Suffragettes who had rushed the barricades and flung stones at Mr. Asquith's departing train received sentences from a fortnight to one month, but Miss Marsh and Mrs. Leigh were sent to prison for three and four months respectively. All of the prisoners adopted the hunger strike, as we knew they would.

Several days later we were horrified to read in the newspapers that these prisoners were being forcibly fed by means of a rubber tube thrust into the stomach. Members of the Union applied at once both at the prison and at the Home Office to learn the truth of the report, but all information was refused. On the following Monday at our request, Mr. Keir Hardie, at question time in the House, insisted on information from the Government. Mr. Masterman, speaking for the Home Secretary, reluctantly admitted that, in order to preserve the dignity of the Government and at the same time save the lives of the prisoners, "hospital treatment" was being administered. "Hospital treatment" was the term used to draw attention from one of the most disgusting and brutal expedients ever resorted to by prison authorities. No law allows it except in the case of persons certified to be insane, and even then when the operation is performed by skilled nursing attendants under the direction of skilled medical men, it cannot be called safe. In fact, the asylum cases usually die after a short time. _The Lancet_, perhaps the best known medical journal in the language, published a long list of opinions from distinguished physicians and surgeons who condemned the practice as applied to the suffrage prisoners as unworthy of civilisation. One physician told of a case which had come under his observation in which death had occurred almost as soon as the tube had been inserted. Another cited a case where the tongue, twisted behind the feeding tube, had, in the struggle, been almost bitten off. Cases where food had been injected into the lungs were not unknown. Mr. C. Mansell-Moullin, M.D., F.R.C.S., wrote to _The Times_ that as a hospital surgeon of more than thirty years' experience he desired indignantly to protest against the Government's term "Hospital treatment" in connection with the forcible feeding of women. It was a foul libel, he declared, for violence and brutality have no place in hospitals. A memorial signed by 116 well-known physicians was addressed to the Prime Minister protesting against the practice of forcible feeding, and pointing out to him in detail the grave dangers attaching to it.

So much for medical testimony against a form of brutality which continued and still continues in our English prisons, as a punishment for women who are there for consciences' sake. As for the testimony of the victims, it makes a volume of most revolting sort. Mrs. Leigh, the first victim, is a woman of sturdy constitution, else she could scarcely have survived the experience. Thrown into Birmingham prison after the Asquith demonstration, she had broken the windows of her cell, and as a punishment was sent to a dark and cold punishment cell. Her hands were handcuffed, behind her during the day, and at night in front of her body _with the

palms out_. She refused to touch the food that was brought to her, and three days after her arrival she was taken to the doctor's room. What she saw was enough to terrify the bravest. In the centre of the room was a stout chair resting on a cotton sheet. Against the wall, as if ready for action stood four wardresses. The junior doctor was also on hand. The senior doctor spoke, saying: "Listen carefully to what I have to say. I have orders from my superior officers that you are not to be released even on medical grounds. If you still refrain from food I must take other measures to compel you to take it." Mrs. Leigh replied that she did still refuse, and she said further that she knew that she could not legally be forcibly fed because an operation could not be performed without the consent of the patient if sane. The doctor repeated that he had his orders and would carry them out. A number of wardresses then fell upon Mrs. Leigh, held her down and tilted her chair backward. She was so taken by surprise that she could not resist successfully that time. They managed to make her swallow a little food from a feeding cup. Later two doctors and the wardresses appeared in her cell, forced Mrs. Leigh down to the bed and held her there. To her horror the doctors produced a rubber tube, two yards in length, and this he began to stuff up her nostril. The pain was so dreadful that she shrieked again and again. Three of the wardresses burst into tears and the junior doctor begged the other to desist. Having had his orders from the Government, the doctor persisted and the tube was pushed down into the stomach. One of the doctors, standing on a chair and holding the tube high poured liquid food through a funnel almost suffocating the poor victim. "The drums of my ears," she said afterwards, "seemed to be bursting. I could feel the pain to the end of the breast bone. When at last the tube was withdrawn it felt as if the back of my nose and throat were being torn out with it."

In an almost fainting condition Mrs. Leigh was taken back to the punishment cell and laid on her plank bed. The ordeal was renewed day after day. The other prisoners suffered similar experiences.

CHAPTER VI

The militant movement was at this point when, in October, 1909, I made my first visit to the United States. I shall never forget the excitement of my landing, the first meeting with the American "reporter," an experience dreaded by all Europeans. In fact the first few days seemed a bewildering whirl of reporters and receptions, all leading up to my first lecture at Carnegie Hall on October 25th. The huge hall was entirely filled, and an enormous crowd of people thronged the streets outside for blocks. With me on the stage were several women whom I had met in Europe, and in the chair was an old friend, Mrs. Stanton Blatch, whose early married life had been spent in England. The great crowd before me, however, was made up of strangers, and I could not know how they would respond to my story. When I rose to speak a deep hush fell, but at my first words: "I am what you call a hooligan--" a great shout of warm and sympathetic laughter shook the walls. Then I knew that I had found friends in America. And this all the rest of the tour demonstrated. In Boston the committee met me with a big grey automobile decorated in the colours of our Union, and that night at Tremont Temple I spoke to an audience of 2,500 people all most generous in their responsiveness. In Baltimore professors, and students from Johns Hopkins University acted as stewards of the meeting. I greatly enjoyed my visit to Bryn Mawr College and to Rosemary Hall, a wonderful school for girls in Connecticut. In Chicago, I met, among other notable people, Miss Jane Addams and Mrs. Ella Flagg Young, superintendent of schools. My visit to Canada will always be remembered, especially Toronto, where the mayor, dressed in the chains of his office, welcomed me. I met too the venerable Goldwin Smith, since dead.

Everywhere I found the Americans kind and keen, and I cannot say too much for the wonderful hospitality they showed me. The women I found were remarkably interested in social welfare. The work of the women's clubs struck me very favourably, and I thought these institutions a perfect basis for a suffrage movement. But at that time, 1909, the suffrage movement in the United States was in a curious state of quiescence. A large number of women with whom I came in contact appeared to think it only just that they should have a vote, but few seemed to realise any actual need of it. Some, it is true, were beginning to connect the vote with the reforms for which they were working so unselfishly and so devotedly. It was when talking with the younger women that I came to feel that under the surface of things in America, a strong suffrage movement was stirring. Those young women, leaving their splendid colleges to begin life were realising in a very intelligent fashion that they needed and would be obliged to secure for themselves a political status.

On December 1st I sailed on the _Mauretania_ for England, and on arriving I learned that the prison sentence which hung over me while the petitions case had been argued, was discharged, some unknown friend having paid my fine while I was on the ocean.

The year 1910 began with a general election, precipitated by the House of Lords' rejection of Mr. Lloyd-George's 1909 budget. The Liberal Party went to the country with promises of taxes on land values. They promised also abolition of the veto power of the Lords, Irish Home Rule, disestablishment of the Church of Wales, and other reforms. Woman suffrage was not directly promised,

but Mr. Asquith pledged that, if retained in office, he would introduce an electoral reform bill which could be amended to include woman suffrage. The Unionists under the leadership of Mr. Balfour, had tariff reform for their programme, and they offered not even a vague promise of a possible suffrage measure. Yet we, as usual, went into the constituencies and opposed the Liberal Party. We had no faith in Mr. Asquith's pledge, and besides, if we had failed to oppose the party in power we should but have invited Mr. Asquith and Mr. Balfour to enter into an agreement not to deal with the suffrage, with the view of keeping the cause permanently outside practical politics. We were in something of the same position as the Irish Nationalists in 1885, when neither the Liberal nor the Conservative leaders would include home rule in their programme. The Irish opposed the Liberal Party, with the result that it was returned by such a narrow majority that the Liberal Government was dependent on the Irish vote in Parliament in order to remain in office. On this account they were obliged to bring in a Home Rule Bill.

The other suffrage societies and many of the Liberal women begged us not to oppose the Liberal party at this election. We were implored to waive our claim "just this once" in view of the importance of the struggle between the Commons and the House of Lords over the budget. We replied that the same plea had been made in 1906 when we were implored to waive our claim "just this once" on account of the fiscal issue. For women there was only one political issue, we said, and that was the issue of their own enfranchisement. The dispute between the Lords and the Commons was far less vital than the claims of the people--represented in this case by women--to be admitted to citizenship. From our point of view both Houses of Parliament were unrepresentative until women had a voice in choosing legislators and influencing law making.

We opposed Liberal candidates in forty constituencies, and in almost every one of these the Liberal majorities were reduced and no less than eighteen seats were wrested from the Liberal candidates. It really was a terrible election for the Government. Mr. Asquith travelled from one constituency to another accompanied by a body guard of detectives, and official "chuckers out," whose sole duty was to eject women, and men as well, who interrupted his meetings on the question of Votes for Women. The halls where he spoke had the windows boarded up or the glass covered with strong wire netting. Every thoroughfare leading to the halls was barricaded, traffic was suspended, and large forces of police were on guard. The most extraordinary precautions were taken to protect the Prime Minister. At one place he went to his meeting strongly guarded and by way of a secret pathway that led through gooseberry bushes and a cabbage patch to a back door. After the meeting he escaped through the same door and was solemnly guided along a path heavily laid with sawdust to deaden his footsteps, to a concealed motor car, where he sat until the crowd had all dispersed.

The other ministers had to resort to similar precautions. They lived under the constant protection of body-guards. Their meetings were policed in a manner without precedent. Of course no women were admitted to their meetings, but they got in just the same. Two women hid for twenty-five hours in the rafters of a hall in Louth where Mr. Lloyd-George spoke. They were arrested, but not until after they had made their demonstration. Two others hid under a platform for twenty-two hours in order to question the Prime Minister. I could continue this record almost indefinitely.

We had printed a wonderful poster showing the process of forcible feeding, and we used it on hoardings everywhere. We told the electors that the "Liberal Party," the people's friend, had imprisoned 450 women for the crime of asking for a vote. They were torturing women at that time in Holloway. It was splendid ammunition and it told. The Liberal Party was returned to power, but with their majority over all sections of the House of Commons swept away. The Asquith Government were dependent now for their very existence on the votes of the Labour Party and the Irish Nationalists.

CHAPTER VII

The first months of 1910 were occupied by the re-elected Government in a struggle to keep control of affairs. A coalition with the Irish party, the leaders of which agreed, if the Home Rule bill were advanced, to stand by the budget. No publicly announced coalition with the Labour Party was made at that time, Keir Hardie, at the annual conference of the party, announcing that they would continue to be independent of the Government. This was important to us because it meant that the Labour Party, instead of entering into an agreement to give general support to all Government measures, would be free to oppose the Government in the event of the continued withholding of a franchise bill. Other things combined to make us hopeful that the tide had turned in our favour. It was hinted to us that the Government were weary of our opposition and were ready to end the struggle in the only possible way, providing they could do so without appearing to yield to coercion. We therefore, early in February, declared a truce to all militancy.

Parliament met on February 15th and the King's speech was read on February 21st. No mention of women's suffrage was made in the speech nor was any private member successful in winning a place in the ballot for a suffrage bill. However, since the situation,

on account of the proposed abolition of the Lord's power of veto, was strained and abnormal, we decided to wait patiently for a while. It was confidently expected that another general election would have to be held before the contentions between the two Houses of Parliament were settled, and this event unquestionably would have occurred, not later than June, but for the unexpected death of King Edward VII. This interrupted the strained situation. The passing of the King served as an occasion for the temporary softening of animosities and produced a general disposition to compromise on all troubled issues. The question of women's enfranchisement was taken up again in this spirit, and in a manner altogether creditable to the members with whom the movement originated.

A strictly non-party committee on women's suffrage had been established in the House of Commons in 1887, mainly through the efforts of Miss Lydia Becker, whom I have mentioned before as the Susan B. Anthony of the English suffrage movement. In 1906, for reasons not necessary to enumerate, the original committee had been allowed to lapse, the Liberal supporters of women's suffrage forming a committee of their own. Now, in this period of good feeling, at the suggestion of certain members, led by Mr. H. N. Brailsford, not himself a member of Parliament, formed another non-party body which they called the Conciliation Committee. Its object was declared to be the bringing together of the full strength of suffragists of the House of Commons, regardless of party affiliation, and of framing a suffrage measure that could be passed by their united effort. The Earl of Lytton accepted the chairmanship of the committee and Mr. Brailsford was made its secretary. The committee consisted of twenty-five Liberals, seventeen Conservatives, six Irish Nationalists, and six members of the Labour Party. Under difficulties which I can hardly hope to make clear to American readers the committee laboured to frame a bill which should win the support of all sections of the House. The Conservatives insisted on a moderate bill, whilst the Liberals were concerned lest the terms of the bill should add to the power of the propertied classes. The original suffrage bill, drafted by my husband. Dr. Pankhurst, giving the vote to women on equal terms with men, was abandoned, and a bill was drawn up along the lines of the existing municipal franchise law. The basis of the municipal franchise is occupation, and the Conciliation Bill, as first drafted, proposed to extend the Parliamentary vote to women householders, and to women occupiers of business premises paying ten pounds rental and upwards. It was estimated that about ninety-five per cent. of the women who would be enfranchised under the bill were householders. This, in England, does not mean a person occupying a whole house. Any one who inhabits even a single room over which he or she exercises full control is a householder.

The text of the Conciliation Bill was submitted to all the suffrage societies and other women's organisations, and it was accepted by every one of them. Our official newspaper said editorially: "We of the Women's Social and Political Union are prepared to share in this united and peaceful action. The new bill does not give us all that we want, but we are for it if others are also for it."

It seemed certain that an overwhelming majority of the House of Commons were for the bill, and were prepared to vote it into law. Although we knew that it could not possibly pass unless the Government agreed that it should, we hoped that the leaders of all parties and the majority of their followers would unite in an agreement that the bill should pass. This settlement by consent is rare in the English Parliament, but some extremely important and hard fought measures have been carried thus. The extension of the franchise in 1867 is a case in point.

The Conciliation Bill was introduced into the House of Commons on June 14th, 1910, by Mr. D. J. Shackleton, and was received with the most extraordinary enthusiasm. The newspapers remarked on the feeling of reality which marked the attitude of the House towards the bill. It was plain that the members realised that here was no academic question upon which they were merely to debate and to register their opinions, but a measure which was intended to be carried through all its stages and to be written into English law. The enthusiasm of the House swept all over the Kingdom. The medical profession sent in a memorial in its favour, signed by more than three hundred of the most distinguished men and women in the profession. Memorials from writers, clergymen, social workers, artists, actors, musicians, were also sent. The Women's Liberal Federation met and unanimously resolved to ask the Prime Minister to give full facilities to the bill. Some advanced spirits in the Federation actually proposed to send then and there a deputation to the House of Commons with the resolution, but this proposal was rejected as savouring too much of militancy. A request for an interview was sent to Mr. Asquith, and he replied promising to receive, at an early day, representatives of both the Liberal Women's Federation and of the National Union of Women's Suffrage Societies.

The joint deputation was received by Mr. Asquith on June 21st, and Lady M'Laren, as a representative of the Women's Liberal Federation, spoke very directly to her party's leader. She said in part: "If you refuse our request we shall have to go to the country and say you, who are against the veto of the House of Lords, are placing a veto on the House of Commons by refusing to allow a second reading of this bill."

Mr. Asquith replied warily that he could not decide alone on such a serious matter, but would have to consult his Cabinet, the majority of whom, he admitted, were suffragists. Their decision, he said, would be given in the House of Commons.

[Illustration: OVER 1,000 WOMEN HAD BEEN IN PRISON--BROAD ARROWS IN THE 1910 PARADE]

The Women's Social and Political Union arranged a demonstration in support of the Conciliation Bill, the greatest that had, up to that time, been made. It was a national, indeed an inter-national affair in which all the suffrage groups took part, and its massed ranks were so great that the procession required an hour and a half to pass a given point. At the head marched six hundred and seventeen women, white clad and holding long silver staves tipped with the broad arrow. These were the women who had suffered imprisonment for the cause, and all along the line of march they received a tribute of cheers from the public. The immense Albert Hall, the largest hall in England, although it was packed from orchestra to the highest gallery, was not large enough to hold all the marchers. Amid great joy and enthusiasm Lord Lytton delivered a stirring address in which he confidently predicted the speedy advance of the bill. The women, he declared, had every reason to believe that their enfranchisement was actually at hand.

It was true that the time for passing a suffrage bill was ripe. Not in fifty years had the way been so clear, because the momentary absence of ordinary legislation left the field open for an electoral reform bill. Yet when the Prime Minister was asked in the House of Commons whether he would give the members an early opportunity for discussion, the answer was not encouraging. The Government, said Mr. Asquith, were prepared to give time before the close of the session for full debate and division on second reading, but they could not allow any further facilities. He stated frankly that he personally did not want the bill to pass, but the Government realised that the House of Commons ought to have an opportunity, if that was their deliberate desire, for effectively dealing with the whole question.

This cryptic utterance was taken by the majority of the suffragists, by the press and by the public generally to mean that the Government were preparing gracefully to yield to the undoubted desire of the House of Commons to pass the bill. But the Women's Social and Political Union were doubtful. Mr. Asquith's remark was ambiguous, and was capable of being interpreted in several ways. It could mean that he was prepared to accept the verdict of the majority and let the bill pass through all its stages. That of course would be the only way to allow the House opportunity effectively to deal with the whole question. On the other hand Mr. Asquith might be intending to let the bill pass through its debating stages and be afterwards smothered in committee. We feared treachery, but in view of the announcement that the Government had set apart July 11 and 12 for debate on the second reading, we preserved a spirit of waiting calm. July 26th had been fixed as the day for the adjournment of Parliament, and if the bill was voted on favourably on the 12th there would be ample time to take it through its final stages. When a bill passes its second reading it is normally sent upstairs to a Grand Committee which sits while the House of Commons is transacting other business, and thus the committee stage can proceed without special facilities. The bill does not go back to the House until the report stage is reached, at which time the third and last reading occurs. After that the bill goes to the House of Lords. A week at most is all that is required for this procedure. A bill may be referred to the Whole House, and in this case it cannot be brought up for its committee stage unless it is given special facilities. In our paper and in many public speeches we urged that the members vote to send the bill to a Grand Committee.

Some days before the bill reached its second reading it was rumoured that Mr. Lloyd-George was going to speak against it, but we refused to credit this. Unfair to women as Mr. Lloyd-George had shown himself in various ways, he had consistently posed as a staunch friend of women's suffrage, and we could not believe that he would turn against us at the eleventh hour. Mr. Winston Churchill, whose speech to the women of Dundee I quoted in a previous chapter, the promoters of the Bill also counted upon, as it was known that he had more than once expressed sympathy with its objects. But when the debates began we found both of these ardent suffragists arrayed against the bill. Mr. Churchill, after making a conventional anti-suffrage speech, in which he said that women did not need the ballot, and that they really had no grievances, attacked the Conciliation Bill because the class of women who would be enfranchised under it did not suit him. Some women, he conceded, ought to be enfranchised, and he thought the best plan would be to select "some of the best women of all classes" on considerations of property, education and earning capacity. These special franchises would be carefully balanced, "so as not on the whole to give undue advantage to the property vote against the wage earning vote." A more fantastic proposal and one less likely to find favour in the House of Commons could not possibly be imagined. Mr. Churchill's second objection to the bill was that it was anti-democratic! It seemed to us that anything was more democratic than his proposed "fancy" franchises.

Mr. Lloyd-George said that he agreed with everything Mr. Churchill had said "both relevant and irrelevant." He made the amazing assertion that the Conciliation Committee that had drafted the bill was a "committee of women meeting outside the House." And

that this committee said to the House of Commons not only that they must vote for a women's suffrage bill but "You must vote for the particular form upon which we agree, and we will not even allow you to deliberate upon any other form."

Of course these statements were wholly false. The Conciliation Bill was drafted by men, and it was introduced because the Government had refused to bring in a party measure. The suffragists would have been only too glad to have had the Government deliberate on a broader form of suffrage. Because they refused to deliberate on any form, this private bill was introduced.

This fact was brought forward in the course of Mr. Lloyd-George's speech. It had been urged, said he, that this bill was better than none at all, but why should that be the alternative? "What is the other?" called out a member, but Mr. Lloyd-George dodged the question with a careless "Well, I cannot say for the present."

Later on he said: "If the promoters of this bill say that they regard the second reading merely as an affirmation of the principle of women's suffrage, and if they promise that when they re-introduce the bill it will be in a form which will enable the House of Commons to move any amendment either for restriction or extension I shall be happy to vote for this bill."

Mr. Philip Snowden, replying to this, said: "We will withdraw this bill if the Right Honourable gentleman, on behalf of the Government, or the Prime Minister himself will undertake to give to this House the opportunity of discussing and carrying through its various stages another form of franchise bill. If we cannot get that, then we shall prosecute this bill."

The Government made no reply at all to this, and the debate proceeded. Thirty-nine speeches were made, the Prime Minister showing plainly in his speech that he intended to use all his power to prevent the bill becoming law. He began by saying that a franchise measure ought never to be sent to a Grand Committee, but to one of the Whole House. He said also that his conditions, that the majority of women should show beyond any doubt that they desired the franchise, and that the bill be democratic in its terms, had not been complied with.

When the division was taken it was seen that the Conciliation Bill had passed its second reading by a majority of 109, a larger majority than the Government's far famed budget or the House of Lords Resolution had received. In fact no measure during that Parliament had received so great a majority--299 members voted for it as against 190 opposed. Then the question arose as to which committee should deal with the bill. Mr. Asquith had said that all franchise bills should go to a Committee of the Whole House, so that in the division his words moved many sincere friends of the bill to send it there. Others understood that this was a mischievous course, but were afraid of incurring the anger of the Prime Minister. Of course all the anti-suffragists voted the same way, and thus the bill went to the Whole House.

Even then the bill could have been advanced to its final reading. The House had time on their hands, as virtually all important legislative work was halted because of the deadlock between the Lords and the Commons. Following the death of the King a conference of leaders of the Conservative and the Liberal Parties had been arranged to adjust the matters at issue, and this conference had not yet reported. Hence Parliament had little business on hand. The strongest possible pressure was brought to bear upon the Government to give facilities to the Conciliation Bill. A number of meetings were held in support of the bill. The Men's Political Union for Women's Enfranchisement, the Men's League for Women's Suffrage and the Conciliation Committee held a joint meeting in Hyde Park. Some of the old school of suffragists held another large meeting in Trafalgar Square. The Women's Social and Political Union, on July 23rd, which was the anniversary of the day in 1867 on which working men, agitating for their vote, had pulled down the Hyde Park railings, held another enormous demonstration there. A space of half a square mile was cleared, forty platforms erected, and two great processions marched from east and west to the meeting. Many other suffrage societies co-operated with us on this occasion. On the very day of that meeting Mr. Asquith wrote to Lord Lytton refusing to allow any more time for the bill during that session.

Those who still had faith that the Government could be induced to do justice to women set their hopes on the autumn session of Parliament. Resolutions urging the Government to give the bill facilities during the autumn were sent, not only by the suffrage associations but from many organisations of men. The Corporations of thirty-eight cities, including Liverpool, Manchester, Glasgow, Dublin and Cork, sent resolutions to this effect. Cabinet Ministers were besieged with requests to receive deputations of women, and since the country was on the verge of a general election, and the Liberal Party wanted the services of women, their requests could not altogether be ignored. Mr. Asquith, early in October, received a deputation of women from his own constituency of East Fife, but all he had to tell them was that the bill could not be advanced that year. "What about next year?" They asked, and he replied shortly: "Wait and see."

It had been exceedingly difficult, during these troublous days, to hold all the members of the W. S. P. U. to the truce, and when it became perfectly apparent that the Conciliation Bill was doomed, war was again declared. At a great meeting held in Albert Hall on November 10th, I myself threw down the gage of battle. I said, because I wanted the whole matter to be clearly understood by the public as well as by our members: "This is the last constitutional effort of the Women's Social and Political Union to secure the passage of the bill into law. If the Bill, in spite of our efforts, is killed by the Government, then first of all, I have to say there is an end of the truce. If we are met by the statement that there is no power to secure on the floor of the House of Commons time for our measure, then our first step is to say, 'We take it out of your hands, since you fail to help us, and we resume the direction of the campaign ourselves.'"

Another deputation, I declared, must go to the House of Commons to carry a petition to the Prime Minister. I myself would lead, and if no one cared to follow me I would go alone. Instantly, all over the hall, women sprang to their feet crying out, "Mrs. Pankhurst, I will go with you!" "I will go!" "I will go!" And I knew that our brave women were as ever ready to give themselves, their very lives, if need be, for the cause of freedom.

The autumn session convened on Friday, November 18th, and Mr. Asquith announced that Parliament would be adjourned on November 28th. While his speech was in progress, 450 women, in small groups, to keep within the strict letter of the law, were marching from Caxton Hall and from the headquarters of the Union.

[Illustration: THE HEAD OF THE DEPUTATION ON BLACK FRIDAY

November, 1910]

How to tell the story of that dreadful day, Black Friday, as it lives in our memory--how to describe what happened to English women at the behest of an English Government, is a difficult task. I will try to tell it as simply and as accurately as possible. The plain facts, baldly stated, I am aware will strain credulity.

Remember that the country was on the eve of a general election, and that the Liberal Party needed the help of Liberal women. This fact made the wholesale arrest and imprisonment of great numbers of women, who were demanding the passage of the Conciliation Bill, extremely undesirable from the Government's point of view. The Women's Liberal Federations also wanted the passage of the Conciliation Bill, although they were not ready to fight for it. What the Government feared, was that the Liberal women would be stirred by our sufferings into refraining from doing election work for the party. So the Government conceived a plan whereby the Suffragettes were to be punished, were to be turned back and defeated in their purpose of reaching the House, but would not be arrested. Orders were evidently given that the police were to be present in the streets, and that the women were to be thrown from one uniformed or ununiformed policeman to another, that they were to be so rudely treated that sheer terror would cause them to turn back. I say orders were given and as one proof of this I can first point out that on all previous occasions the police had first tried to turn back the deputations and when the women persisted in going forward, had arrested them. At times individual policemen had behaved with cruelty and malice toward us, but never anything like the unanimous and wholesale brutality that was shown on Black Friday.

The Government very likely hoped that the violence of the police towards the women would be emulated by the crowds, but instead the crowds proved remarkably friendly. They pushed and struggled to make a clear pathway for us, and in spite of the efforts of the police my small deputation actually succeeded in reaching the door of the Strangers' Entrance. We mounted the steps to the enthusiastic cheers of the multitudes that filled the streets, and we stood there for hours gazing down on a scene which I hope never to look upon again.

At intervals of two or three minutes small groups of women appeared in the square, trying to join us at the Strangers' Entrance. They carried little banners inscribed with various mottoes, "Asquith Has Vetoed Our Bill," "Where There's a Bill There's a Way," "Women's Will Beats Asquith's Won't," and the like. These banners the police seized and tore in pieces. Then they laid hands on the women and literally threw them from one man to another. Some of the police used their fists, striking the women in their faces, their breasts, their shoulders. One woman I saw thrown down with violence three or four times in rapid succession, until at last she lay only half conscious against the curb, and in a serious condition was carried away by kindly strangers. Every moment the struggle grew fiercer, as more and more women arrived on the scene. Women, many of them eminent in art, in medicine and science, women of European reputation, subjected to treatment that would not have been meted out to criminals, and all for the offence of insisting upon the right of peaceful petition.

[Illustration: FOR HOURS SCENES LIKE THIS WERE ENACTED ON BLACK FRIDAY

November, 1910]

This struggle lasted for about an hour, more and more women successfully pushing their way past the police and gaining the steps of the House. Then the mounted police were summoned to turn the women back. But, desperately determined, the women, fearing not the hoofs of the horses or the crushing violence of the police, did not swerve from their purpose. And now the crowds began to murmur. People began to demand why the women were being knocked about; why, if they were breaking the law, they were not arrested; why, if they were not breaking the law, they were not permitted to go on unmolested. For a long time, nearly five hours, the police continued to hustle and beat the women, the crowds becoming more and more turbulent in their defence. Then, at last the police were obliged to make arrests. One hundred and fifteen women and four men, most of them bruised and choked and otherwise injured, were arrested.

While all this was going on outside the House of Commons, the Prime Minister was obstinately refusing to listen to the counsels of some of the saner and more justice-loving members of the House. Keir Hardie, Sir Alfred Mondell and others urged Mr. Asquith to receive the deputation, and Lord Castlereagh went so far as to move as an amendment to a Government proposal, another proposal which would have compelled the Government to provide immediate facilities to the Conciliation Bill. We heard of what was going on, and I sent in for one and another friendly member and made every possible effort to influence them in favour of Lord Castlereagh's amendment. I pointed to the brutal struggle that was going on in the square, and I begged them to go back and tell the others that it must be stopped. But, distressed as some of them undoubtedly were, they assured me that there was not the slightest chance for the amendment.

"Is there not a single _man_ in the House of Commons," I cried, "one who will stand up for us, who will make the House see that the amendment must go forward?"

Well, perhaps there were men there, but all save fifty-two put their party loyalty before their manhood, and, because Lord Castlereagh's proposal would have meant censure of the Government, they refused to support it. This did not happen, however, until Mr. Asquith had resorted to his usual crafty device of a promise of future action. In this instance he promised to make a statement on behalf of the Government on the following Tuesday.

The next morning the suffrage prisoners were arraigned in police court. Or rather, they were kept waiting outside the court room while Mr. Muskett, who prosecuted on behalf of the Chief Commissioner of Police, explained to the astounded magistrate that he had received orders from the Home Secretary that the prisoners should all be discharged. Mr. Churchill it was declared, had had the matter under careful consideration, and had decided that "no public advantage would be gained by proceeding with the prosecution, and accordingly no evidence would be given against the prisoners."

Subdued laughter and, according to the newspapers, some contemptuous booing were raised in the court, and when order was restored the prisoners were brought in in batches and told that they were discharged.

On the following Tuesday the W. S. P. U. held another meeting of the Women's Parliament in Caxton Hall to hear the news from the House of Commons. Mr. Asquith said: "The Government will, if they are still in power, give facilities in the next Parliament for effectively proceeding with a franchise bill which is so framed as to admit of free amendment." He would not promise that this would be done during the first year of Parliament.

We had demanded facilities for the Conciliation Bill, and Mr. Asquith's promise was too vague and too ambiguous to please us. The Parliament now about to be dissolved had lasted a scant ten months. The next one might not last longer. Therefore, Mr. Asquith's promise, as usual, meant nothing at all. I said to the women, "I am going to Downing Street. Come along, all of you." And we went.

We found a small force of police in Downing Street, and we easily broke through their line and would have invaded the Prime Minister's residence had not reinforcements of police arrived on the scene. Mr. Asquith himself appeared unexpectedly, and as we thought, very opportunely. Before he could have realised what was happening he found himself surrounded by angry Suffragettes. He was well hooted and, it is said, well shaken, before he was rescued by the police. As his taxicab rushed away some object struck one of the windows, smashing it.

Another Cabinet Minister, Mr. Birrell, unwittingly got into the midst of the melee, and I am obliged to record that he was pretty thoroughly hustled. But it is not true that his leg was injured by the women. His haste to jump into a taxicab resulted in a slightly

sprained ankle.

That night and the following day windows were broken in the houses of Sir Edward Grey, Mr. Winston Churchill, Mr. Lewis Harcourt and Mr. John Burns; and also in the official residences of the Premier and the Chancellor of the Exchequer.

That week 160 Suffragettes were arrested, but all except those charged with window-breaking or assault were discharged. This amazing court action established two things: First, that when the Home Secretary stated that he had no responsibility for the prosecution and sentencing of Suffrage prisoners, he told a colossal falsehood; and second, that the Government fully realised that it was bad election tactics to be responsible for the imprisonment of women of good character who were struggling for citizenship.

CHAPTER VIII

Almost immediately after the events chronicled in the preceding chapter I sailed for my second tour through the United States. I was delighted to find a thoroughly alive and progressive suffrage movement, where before had existed with most people only an academic theory in favour of equal political rights between men and women. My first meeting, held in Brooklyn, was advertised by sandwich women walking through the principal streets of the city, quite like our militant suffragists at home. Street meetings, I found, were now daily occurrences in New York. The Women's Political Union had adopted an election policy, and throughout the country as far west as I travelled, I found women awakened to the necessity of political action instead of mere discussion of suffrage.

My second visit to America, like my first one, is clouded in my memory with sorrow. Very soon after my return to England a beloved sister, Mrs. Mary Clarke died. My sister, who was a most ardent suffragist and a valued worker in the Women's Social and Political Union, was one of the women who was shockingly maltreated in Parliament Square on Black Friday. She was also one of the women who, a few days later, registered their protest against the Government by throwing a stone through the window of an official residence. For this act she was sent to Holloway prison for a term of one month. Released on December 21st, it was plain to those who knew her best that her health had suffered seriously from the dreadful experience of Black Friday and the after experience of prison. She died suddenly on Christmas day, to the profound sorrow of all her associates. Hers was not the only life that was sacrificed as a result of that day. Other deaths occurred, mostly from hearts weakened by overstrain. Miss Henria Williams died on January 2nd, 1911, from heart failure. Miss Cecelia Wolseley Haig was another victim. Ill treatment on Black Friday resulted in her case in a painful illness which ended, after a year of intense suffering, in her death on December 21st, 1911.

It is not possible to publish a full list of all the women who have died or have been injured for life in the course of the suffrage agitation in England. In many cases the details have never been made public, and I do not feel at liberty to record them here. A very celebrated case, which is public property, is that of Lady Constance Lytton, sister of the Earl of Lytton, who acted as chairman of the Conciliation Committee. Lady Constance had twice in 1909 gone to prison as a result of suffrage activities, and on both occasions had been given special privileges on account of her rank and family influence. In spite of her protests and her earnest pleadings to be accorded the same treatment as other suffrage prisoners, the snobbish and cowardly authorities insisted in retaining Lady Constance in the hospital cells and discharging her before the expiration of her sentence. This was done on a plea of her ill health, and it was true that she suffered from a valvular disease of the heart.

[Illustration: RIOT SCENES ON BLACK FRIDAY

November, 1910]

Smarting under the sense of the injustice done her comrades in this discrimination, Lady Constance Lytton did one of the most heroic deeds to be recorded in the history of the suffrage movement. She cut off her beautiful hair and otherwise disguised herself, put on cheap and ugly clothing, and as "Jane Warton" took part in a demonstration at Newcastle, again suffering arrest and imprisonment. This time the authorities treated her as an ordinary prisoner. Without testing her heart or otherwise giving her an adequate medical examination, they subjected her to the horrors of forcible feeding. Owing to her fragile constitution she suffered frightful nausea each time, and when on one occasion the doctor's clothing was soiled, he struck her contemptuously on the cheek. This treatment was continued until the identity of the prisoner suddenly became known. She was, of course, immediately released, but she never recovered from the experience, and is now a hopeless invalid.[2]

I want to say right here, that those well-meaning friends on the outside who say that we have suffered these horrors of prison, of hunger strikes and forcible feeding, because we desired to martyrise ourselves for the cause, are absolutely and entirely mistaken.

We never went to prison in order to be martyrs. We went there in order that we might obtain the rights of citizenship. We were willing to break laws that we might force men to give us the right to make laws. That is the way men have earned their citizenship. Truly says Mazzini that the way to reform has always led through prison.

The result of the general election, which took place in January, 1911, was that the Liberal Party was again returned to power. Parliament met on January 31st, but the session formally opened on February 6th with the reading of the King's speech. The programme for the session included the Lords' veto measure, Home Rule, payment for members of Parliament, and the abolishment of plural voting. Invalid insurance was also mentioned and certain amendments to the old age pension bill. Women's suffrage was not mentioned. Nevertheless, we were singularly lucky, the first three places in the ballot being secured by members of the Conciliation Committee. Mr. Philips, an Irish member, drew the first place, but as the Irish party had decided not to introduce any bills that session, he yielded to Sir George Kemp, who announced that he would use his place for the purpose of taking a second reading debate on the new Conciliation Bill. The old bill had been entitled: "A Bill to give the Vote to Women Occupiers," a title that made amendment difficult. The new bill bore the more flexible title, "A Bill to Confer the Parliamentary Franchise on Women," thus doing away with one of Mr. Lloyd-George's most plausible objections to it. The L10 occupation clause was omitted, doing away with another objection, that of the possibility of "faggot voting," that is, of a rich man conferring the vote on a family of daughters by the simple expedient of making them tenants of slices of his own property. The Conciliation Bill now read: "1. Every woman possessed of a household qualification within the meaning of the Representation of the People Act (1884) shall be entitled to be registered as a voter, and when registered to vote in the county or borough in which the qualifying premises are situated.

"2. For the purposes of this Act a woman shall not be disqualified by marriage for being registered as a voter, provided that a husband and wife shall not both be registered as voters in the same Parliamentary borough or county division."

This bill met with even warmer approval than the first one, because it was believed that it would win votes from those members who felt that the original measure had fallen short of being truly democratic. Nevertheless, the Prime Minister showed from the first that he intended to oppose it, as he had all previous suffrage measures. He announced that all Fridays up to Easter and also all time on Tuesdays and Wednesdays usually allowed for private members' bills were to be occupied with consideration of Government measures. Hardly a Liberal voice was raised against this arbitrary ruling. The Irish members indeed were delighted with it, since it gave the Home Rule Bill an advantage. The Labour members seemed complacent, and the rest of the coalition were indifferent. One back bench Liberal went so far as to rise and thank the Prime Minister for the courtesy with which the gagging process was accomplished. There was some show of fight made by the Opposition, but Conservative indignation was tempered by the reflection that the precedent established might be followed to advantage when their party came into power.

Sir George Kemp then announced that he would take May 5th for the second reading of the Conciliation Bill, and the supporters of the bill, according to their various convictions, set to work to further its interests. The conviction of the W. S. P. U. was that Mr. Asquith's Government would never allow the bill to pass until they were actually forced to do so, and we adopted our own methods to secure a definite pledge from the Government that they would give facilities to the bill.

In April of that year the census was to be taken, and we organised a census resistance on the part of women. According to our law the census of the entire kingdom must be taken every ten years on a designated day. Our plan was to reduce the value of the census for statistical purposes by refusing to make the required returns. Two ways of resistance presented themselves. The first and most important was direct resistance by occupiers who should refuse to fill in the census papers. This laid the register open to a fine of L5 or a month's imprisonment, and thus required the exercise of considerable courage. The second means of resistance was evasion--staying away from home during the entire time that the enumerators were taking the census. We made the announcement of this plan and instantly there ensued a splendid response from women and a chorus of horrified disapproval from the conservative public. The _Times_ voiced this disapproval in a leading article, to which I replied, giving our reasons for the protest. "The Census," I wrote, "is a numbering of the people. Until women count as people for the purpose of representation in the councils of the nation as well as for purposes of taxation, we shall refuse to be numbered."

On the subject of laws made by men--without the assistance of women--for the protection of women and children, I have a very special feeling. From my experience as poor law guardian and as Registrar of Births and Deaths, I know how ridiculously, say rather how tragically, these laws fall short of protection. Take for instance the vaunted "Children's Charter" of 1906, the measure which spread Mr. Lloyd-George's fame throughout the world. A volume could be filled with the mistakes and the cruelties of that Act, the object of which is the preservation and improvement of child life. A distinguishing characteristic of the Act is that it puts most of the responsibility for neglect of children on the backs of the mothers, who, under the laws of England, have no rights as

parents. Two or three especially striking cases of this kind came into notice about this time, and gave the census resistance an additional justification.

The case of Annie Woolmore was a very pitiful one. She was arrested and sentenced to Holloway for six weeks for neglecting her children. The evidence showed that the woman lived with her husband and children in a miserable hovel, which would have been almost impossible to keep clean even if there had been water in the house. As it was the poor soul, who was in ill health and weakened by deprivation, had to carry all the water she used across a great distance. The children as well as the house were very dirty, it was true, but the children were well nourished and kindly treated. The husband, a labourer, out of work much of the time, testified that his wife "starved herself to feed the kids." Yet she had violated the terms of the "Children's Charter" and she went to prison. I am glad to say that owing to the efforts of suffragists she was pardoned and provided with a better home.

Another case was that of Helen Conroy, who was charged with living in one wretched room, with her husband and seven children, the youngest a month old. According to the law the mother was forbidden to have this infant in bed with her overnight, yet part of the charge against her was that the child was found sleeping in a box of damp straw. Doubtless she would have preferred a cradle, or even a box of dry straw. But direst poverty made the cradle impossible and the conditions of the tenement kept the straw damp. Both parents in this instance were sent to prison for three months at hard labour. The magistrate casually remarked that the house in which these poor people lived had been condemned two years before, but some respectable property owner was still collecting rents from it.

Another poor mother, evicted from her home because she could not pay the rent, took her four children out into the open country, and when found was sleeping with them in a gravel pit. She was sent to prison for a month and the children went to the workhouse.

These sorry mothers, logical results of the subjection of women, are enough in themselves to justify almost any defiance of a Government who deny the women the right to work out their destinies in freedom. No pledge having been secured from the Prime Minister by April 1st, we carried out, and most successfully, our census resistance. Many thousands of women all over the country refused or evaded the returns. I returned my census paper with the words "No vote no census" written across it, and other women followed that example with similar messages. One woman filled in the blank with full information about her one man servant, and added that there were many women but no more persons in her household. In Birmingham sixteen women of wealth packed their houses with women resisters. They slept on the floors, on chairs and tables, and even in the baths. The head of a large college threw open the building to 300 women. Many women in other cities held all night parties for friends who wished to remain away from home. In some places unoccupied houses were rented for the night by resisters, who lay on the bare boards. Some groups of women hired gipsy vans and spent the night on the moors.

In London we gave a great concert at Queen's Hall on Census night. Many of us walked about Trafalgar Square until midnight and then repaired to Aldwich skating rink, where we amused ourselves until morning. Some skated while others looked on, and enjoyed the admirable musical and theatrical entertainment that helped to pass the hours. We had with us a number of the brightest stars in the theatrical world, and they were generous in their contributions. It being Sunday night, the chairman had to call on each of the artists for a "speech" instead of a song or other turn. An all-night restaurant near at hand did a big business, and on the whole the resisters had a very good time. The Scala Theatre was the scene of another all-night entertainment.

There was a good deal of curiosity to see what the Government would devise in the way of a punishment for the rebellious women, but the Government realised the impossibility of taking punitive action, and Mr. John Burns, who, as head of the Local Government Board, was responsible for the census, announced that they had decided to treat the affair with magnanimity. The number of evasions, he declared, was insignificant. But every one knew that this was the exact reverse of the facts.

[Illustration: IN THIS MANNER THOUSANDS OF WOMEN THROUGHOUT THE KINGDOM SLEPT IN UNOCCUPIED HOUSES OVER CENSUS NIGHT]

The Conciliation Bill was debated on May 5th and passed its second reading by the enormous majority of 137. And now the public and a section of the press united in a strong demand that the Government yield to the undoubted will of the House and grant facilities to the bill. The Conciliation Committee sent a deputation of members to the Prime Minister to remind him of his pre-election promise that the House of Commons should have an opportunity of dealing with the whole question of woman suffrage, but they succeeded only in getting his assurance that he had the matter under consideration. Late in the month the announcement was made in the House that the Government would not grant facilities during that session, but, since the new bill fulfilled the conditions named by the Prime Minister, and was now capable of amendment, the Government recognised it to be their duty to grant facilities

in some session of the present Parliament. They would be prepared next session, when the bill had been again read for the second time, either as a result of obtaining a good place in the ballot, or (if that did not happen) by a grant of a Government day for the purpose, to give a week, which they understood to be the time suggested as reasonable by the promoters for its further stages.

This pledge was made in order to deter the W. S. P. U. from making a militant demonstration in connection with the coronation of the King.

Keir Hardie asked if the Government would, by means of a closure or otherwise, make certain that the bill would go through in the week, and the Prime Minister replied, "No, I cannot give an assurance of that kind. After all, it is a problem of the very greatest magnitude."

This reply seemed to make the Government's pledge practically worthless. The Conciliation Committee also realised the possibilities of the bill being talked out, and Lord Lytton wrote to Mr. Asquith and asked him for assurances that the facilities offered were intended not for academic discussion but for effective opportunity for carrying the bill. He also asked that the week offered should not be construed rigidly but that, providing the committee stage were got through in the time, additional days for the report and third reading stages might be forthcoming. Reasonable opportunity for making use of the closure was also asked. To Lord Lytton's letter the Prime Minister replied as follows:

My dear Lytton--In reply to your letter on the subject of the Women's Enfranchisement Bill, I would refer you to some observations recently made in a speech at the National Liberal Club by Sir Edward Grey, which accurately expresses the intention of the Government.

It follows (to answer your specific inquiries), that the "week" offered will be interpreted with reasonable elasticity, that the Government will interpose no reasonable obstacle to the proper use of the closure, and that if (as you suggest) the bill gets through committee in the time proposed, the extra days required for report and third reading will not be refused.

The Government, though divided in opinion on the merits of the bill, are unanimous in their determination to give effect, not only in the letter but in the spirit, to the promise in regard to facilities which I made on their behalf before the last general election. Yours etc., H. H. ASQUITH.

Sceptical up to this point, the W. S. P. U. was now convinced that the Government were sincere in their promise to give the bill full facilities in the following year. We held a joyful mass meeting in Queen's Hall and I again declared that warfare against the Government was at an end. Our new policy was the inauguration of a great holiday campaign, with the object of making victory in 1912 absolutely certain. Electors must be aroused, members of Parliament held to their allegiance. Women must be organised in order that questions that vitally affect the social welfare of the country might be placed before them. I chose Scotland and Wales as the scenes of my holiday labours.

I may say that our confidence was fully shared by the public at large. The belief in Mr. Asquith's pledge was accurately reflected in a leader published in _The Nation_, which said: "From the moment the Prime Minister signed the frank and ungrudging letter to Lord Lytton which appeared in last Saturday's newspapers, women became, in all but the legal formality, voters and citizens. For at least two years, if not for longer, nothing has been lacking save a full and fair opportunity for the House of Commons to translate its convictions into the precise language of a statute. That opportunity has been promised for next session and promised in terms and under conditions which ensure success."

The only thing, as we thought, that we had to fear were wrecking amendments to the bill, and in the new by-election policy which we adopted we worked against all candidates of every party who would refuse to promise, not only to support the Conciliation Committee to carry the bill, but also to vote against any amendment the committee thought dangerous. We believed that we had covered every possibility of disaster. But we had something yet to learn of the treachery of the Asquith Ministry and their capacity for cold-blooded lying.

Mr. Lloyd-George from the first was an open enemy of the bill, but since we had no doubt of the sincerity of the Prime Minister, we could only conclude that Mr. Lloyd-George had detached himself from the main body of the Government and had become the self-constituted leader of the opposition. In an address to a large Liberal group Mr. Lloyd-George advised that Liberal members be asked to ballot for a place for a "democratic measure," in order that such a measure might claim the Prime Minister's pledge for facilities next session. In one or two other speeches he made vague allusions to the possibilities of introducing another suffrage bill.

His own idea was to amend the bill to give a vote to wives of all electors--making married women voters in virtue of their husband's qualification. The inevitable effect of such an amendment would be to wreck the bill, since it would have enfranchised about 6,000,000 women in addition to the million and a half who would benefit by the original terms of the bill. Such a wholesale addition to the electorate was never known in England; the number enfranchised by the Reform Bill of 1832 being hardly more than half a million. The Reform Bill of 1867 admitted a million new voters, and that of 1884 perhaps two millions. The absurdity of Mr. Lloyd-George's proposition was such that we did not regard it seriously. We did not allow his opposition to give us serious alarm until a day in August when a Welsh member, Mr. Leif Jones, asked the Prime Minister from the floor of the House, whether he was aware that his promise for facilities for the Conciliation Bill in the next session was being claimed exclusively for that bill, and asked further for a statement that the promised facilities would be equally granted to any other suffrage bill that might secure a second reading and was capable of amendment. Mr. Lloyd-George, speaking for the Government, replied that they could not undertake to give facilities to more than one bill on the same subject, but that any bill which, satisfying these tests, secured a second reading, would be treated by them as falling within their engagements.

Astounded at this plain evasion of a sacred promise, Lord Lytton again wrote to the Prime Minister, reviewing the entire matter, and asking for another statement of the Government's intentions. The following is the text of Mr. Asquith's reply:

My dear Lytton--I have no hesitation in saying that the promises made by, and on behalf of the Government, in regard to giving facilities to the Conciliation Bill, will be strictly adhered to, both in letter and in spirit. Yours sincerely, H. H. ASQUITH. August 23, 1911.

Again we were reassured, and our confidence in the Premier's pledge remained unshaken throughout the campaign, although Mr. Lloyd-George continued to throw out hints that the promises of facilities for the bill were altogether illusory. We could not believe him, and when, two months later, I was asked in America: "When will English women vote?" I replied with perfect conviction, "Next year."

This was in Louisville, Kentucky, where I attended the 1911 Annual Convention of the National American Woman Suffrage Association.

I remember this third visit to the United States with especial pleasure. I was the guest in New York of Dr. and Mrs. John Winters Brannan, and through the courtesy of Dr. Brannan, who is at the head of all the city hospitals, I saw something of the penal system and the institutional life of America. We visited the workhouse and the penitentiary on Blackwell's Island, and although I am told that these places are not regarded as model institutions, I can assure my readers that they are infinitely superior to the English prisons where women are punished for trying to win their political freedom. In the American prisons, much as they lacked in some essentials, I saw no solitary confinement, no rule of silence, no deadly air of officialdom. The food was good and varied, and above all there was an air of kindness and good feeling between the officials and the prisoners that is almost wholly lacking in England.

But, after all, in the United States as in other countries, the problem of the relations between unfranchised women and the State remains unsolved and unsatisfactory. One night my friends took me to that sombre and terrible institution, the Night Court for Women. We sat on the bench with the magistrate, and he very courteously explained everything to us. The whole business was heart-breaking. All the women, with one exception--an old drunkard--were charged with solicitation. Most of them were of high type by nature. It all seemed so hopeless, and it was clear that they were victims of an evil system. Their conviction was a foregone conclusion.

The magistrate said that in most cases the reason for their coming there was economic. One case of a little cigar maker, who said very simply that she only went on the streets when out of work, and that when in work she earned $8 a week, was very tragic and touching. I could not keep the Night Court out of my speeches after that. The whole dreadful injustice of women's lives seemed mirrored in that place.

I went as far west as the Pacific Coast on this visit, spending Christmas day in Seattle, and for the first time seeing a community where women and men existed on terms of exact equality. It was a delightful experience. As I wrote home to our members, the men of the western States seemed to my eyes eager, earnest, rough men, building a great community in a great hurry, but never have I seen greater respect, courtesy and chivalry shown to women than in that one Suffrage State it has been my privilege to visit.

I am getting a little ahead of my story, however. It was in November, when I was in the city of Minneapolis, that a crushing blow descended on the English suffragists. I learned of this through cabled despatches in the newspapers and from private cables, and

was so staggered that I could scarcely command myself sufficiently to fill my immediate engagements. This was the news, that the Government had broken their plighted word and had deliberately destroyed the Conciliation Bill. My first wild thought, on hearing of this act of treachery, was to cancel all engagements and return to England, but my final decision to remain afterwards proved the right one, because the women at home, without a moment's loss of time, struck the answering blow, guided by that insight which has been characteristic of every act of the members of our Union. I did not return to England until January 11, 1912, and by that time great deeds had been done. Our movement had entered upon a new and more vigorous stage of militancy.

FOOTNOTE:

[2] Lady Constance Lytton's story has been thrillingly told in her book "Prisons and Prisoners," Heinemann.

BOOK III

THE WOMEN'S REVOLUTION

CHAPTER I

Parliament had reassembled on October 25th, 1911, and the first move on the part of the Government was, to say the least of it, rather unpropitious. The Prime Minister submitted two motions, the first one empowering them to take all the time of the House during the remainder of the session, and the second guillotining discussion on the Insurance Bill so as to force the measure through before Christmas. One day only was allotted to the clauses relating to women in that bill. These clauses were notoriously unfair; they provided for sickness insurance of about four million women and unemployment insurance of no women at all. Under the provision of the bill eleven million men were ensured against sickness and about two and a half million against unemployment. Women were given lower benefits for the same premium as men, and premiums paid out of the family income were credited solely to the men's account. The bill as drafted provided no form of insurance for wives, mothers and daughters who spent their lives at home working for the family. It penalised women for staying in the home, which most men agree is women's only legitimate sphere of action. The amended bill grudgingly allowed aside from maternity benefits, a small insurance, on rather difficult terms, for workingmen's wives.

Thus the re-elected Government's first utterance to women was one of contempt; and this was followed, on November 7th, by the almost incredible announcement that the Government intended, at the next session, to introduce a manhood suffrage bill. This announcement was not made in the House of Commons, but to a deputation of men from the People's Suffrage Federation, a small group of people who advocated universal adult suffrage. The deputation, which was very privately arranged for, was received by Mr. Asquith, and the then Master of Elibank (Chief Liberal Whip). The spokesman asked Mr. Asquith to bring in a Government measure for universal adult suffrage, including adult women. The Prime Minister replied that the Government had pledged facilities for the Conciliation Bill, which was as far as they were prepared to go in the matter of women's suffrage. But, he added, the Government intended in the next session to introduce and to pass through all its stages a genuine reform bill which would sweep away existing qualifications for the franchise, and substitute a single qualification of residence. The bill would apply to adult males only, but it would be so framed as to be open to a woman suffrage amendment in case the House of Commons desired to make that extension and amendment.

This portentous announcement came like a bolt from the blue, and there was strong condemnation of the Government's treachery to women. Said the _Saturday Review_:

With absolutely no demand, no ghost of a demand, for more votes for men, and with--beyond all cavil--a very strong demand for votes for women, the Government announce their Manhood Suffrage Bill and carefully evade the other question! For a naked, avowed plan of gerrymandering no Government surely ever did beat this one.

The _Daily Mail_ said that the "policy which Mr. Asquith proposes is absolutely indefensible." And the _Evening Standard and Globe_ said: "We are no friends of female suffrage, but anything more contemptible than the attitude assumed by the Government it is difficult to imagine."

If the Government hoped to deceive any one by their dishonest reference to the possibility of a woman suffrage amendment, they were disappointed. Said the _Evening News_:

Mr. Asquith's bombshell will blow the Conciliation Bill to smithereens, for it is impossible to have a manhood suffrage for men and a property qualification for women. True, the Premier consents to leave the question of women's suffrage to the House, but he knows well enough what the decision of the House will be. The Conciliation Bill had a chance, but the larger measure has none at all.

I have quoted these newspaper leaders to show you that our opinion of the Government's action was shared even by the press. Universal suffrage in a country where women are in a majority of one million is not likely to happen in the lifetime of any reader of this volume, and the Government's generous offer of a possible amendment was nothing more than a gratuitous insult to the suffragists.

The truce, naturally, came to an abrupt end. The W. S. P. U. wrote to the Prime Minister, saying that consternation had been aroused by the Government's announcement, and that it had been decided accordingly to send a deputation representing the Women's Social and Political Union to wait upon himself and the Chancellor of the Exchequer, on the evening of November 21st. The purpose of the deputation was to demand that the proposed manhood suffrage bill be abandoned, and that in its place should be introduced a Government measure giving equal franchise rights to men and women. A similar letter was despatched to Mr. Lloyd-George.

Six times before on occasions of crisis had the W. S. P. U. requested an interview with Mr. Asquith, and each time they had been refused. This time the Prime Minister replied that he had decided to receive a deputation of the various suffrage societies on November 17th, "including your own society, if you desire it." It was proposed that each society appoint four representatives as members of the deputation which would be received by the Prime Minister and the Chancellor of the Exchequer.

Nine suffrage societies sent representatives to the meeting, our own representatives being Christabel Pankhurst, Mrs. Pethick Lawrence, Miss Annie Kenney, Lady Constance Lytton and Miss Elizabeth Robins. Christabel and Mrs. Lawrence spoke for the Union, and they did not hesitate to accuse the two Ministers to their faces of having grossly tricked and falsely misled women. Mr. Asquith, in his reply to the deputation, resented these imputations.

He had kept his pledge, he insisted, in regard to the Conciliation Bill. He was perfectly willing to give facilities to the Bill, if the women preferred that to an amendment to his reform bill. Moreover, he denied that he had made any new announcement. As far back as 1908 he had distinctly declared that the Government regarded it as a sacred duty to bring forward a manhood suffrage bill before that Parliament came to an end. It was true that the Government did not carry out that binding obligation, and it was also true that until the present time nothing more was ever said about a manhood suffrage bill, but that was not the Government's fault. The crisis of the Lord's veto, had momentarily displaced the bill. Now he merely proposed to fulfil his promise made in 1908, and also his promise about giving facilities to the Conciliation Bill. He was ready to keep both promises. Well he knew that those promises were incompatible, that the fulfilment of both was therefore impossible, and Christabel told him so bluntly and fearlessly. "We are not satisfied," she warned him, and the Prime Minister said acidly: "I did not expect to satisfy _you_."

The reply of the W. S. P. U. was immediate and forceful. Led by Mrs. Pethick Lawrence, our women went out with stones and hammers and broke hundreds of windows in the Home Office, the War and Foreign Offices, the Board of Education, the Privy Council Office, the Board of Trade, the Treasury, Somerset House, the National Liberal Club, several post offices, the Old Banqueting Hall, the London and South Western Bank, and a dozen other buildings, including the residence of Lord Haldane and Mr. John Burns. Two hundred and twenty women were arrested and about 150 of them sent to prison for terms varying from a week to two months.

One individual protest deserves mention because of its prophetic character. In December Miss Emily Wilding Davison was arrested for attempting to set fire to a letter box at Parliament Street Post Office. In court Miss Davison said that she did it as a protest against the Government's treachery, and as a demand that women's suffrage be included in the King's speech. "The protest was meant to be serious," she said, "and so I adopted a serious course. In past agitation for reform the next step after window-breaking was incendiarism, in order to draw the attention of the private citizens to the fact that this question of reform was their concern as well as that of women."

Miss Davison received the severe sentence of six months' imprisonment for her deed.

To this state of affairs I returned from my American tour. I had the comfort of reflecting that my imprisoned comrades were being accorded better treatment than the early prisoners had known. Since early in 1910 some concessions had been granted, and some acknowledgment of the political character of our offences had been made. During the brief period when these scant concessions to

justice were allowed, the hunger strike was abandoned and prison was robbed of its worst horror, forcible feeding. The situation was bad enough, however, and I could see that it might easily become a great deal worse. We had reached a stage at which the mere sympathy of members of Parliament, however sincerely felt, was no longer of the slightest use. Reminding our members this, in the first speeches made after returning to England I asked them to prepare themselves for more action. If women's suffrage was not included in the next King's speech we should have to make it absolutely impossible for the Government to touch the question of the franchise.

The King's speech, when Parliament met in February, 1912, alluded to the franchise question in very general terms. Proposals, it was stated, would be brought forward for the amendment of the law with respect to the franchise and the registration of electors. This might be construed to mean that the Government were going to introduce a manhood suffrage bill or a bill for the abolition of plural voting, which had been suggested in some quarters as a substitute for the manhood suffrage bill. No precise statement of the Government's intentions was made, and the whole franchise question was left in a cloud of uncertainty. Mr. Agg Gardner, a Unionist member of the Conciliation Committee, drew the third place in the ballot, and he announced that he should reintroduce the Conciliation Bill. This interested us very slightly, for knowing its prospect of success to have been destroyed, for we were done with the Conciliation Bill forever. Nothing less than a Government measure would henceforth satisfy the W. S. P. U., because it had been clearly demonstrated that only a Government measure would be allowed to pass the House of Commons. With sublime faith, or rather with a deplorable lack of political insight, the Women's Liberal Federation and the National Union of Women's Suffrage Societies professed full confidence in the proposed amendment to a manhood suffrage bill, but we knew how futile was that hope. We saw that the only course to take was to offer determined opposition to any measure of suffrage that did not include as an integral part, equal suffrage for men and women.

On February 16th we held a large meeting of welcome to a number of released prisoners who had served two and three months for the window breaking demonstration that had taken place in the previous November. At this meeting we candidly surveyed the situation and agreed on a course of action which we believed would be sufficiently strong to prevent the Government from advancing their threatened franchise bill. I said on this occasion:

"We don't want to use any weapons that are unnecessarily strong. If the argument of the stone, that time-honoured official political argument, is sufficient, then we will never use any stronger argument. And that is the weapon and the argument that we are going to use next time. And so I say to every volunteer on our demonstration, 'Be prepared to use that argument.' I am taking charge of the demonstration, and that is the argument I am going to use. I am not going to use it for any sentimental reason, I am going to use it because it is the easiest and the most readily understood. Why should women go to Parliament Square and be battered about and insulted, and most important of all, produce less effect than when we throw stones? We tried it long enough. We submitted for years patiently to insult and assault. Women had their health injured. Women lost their lives. We should not have minded if that had succeeded, but that did not succeed, and we have made more progress with less hurt to ourselves by breaking glass than ever we made when we allowed them to break our bodies.

"After all, is not a woman's life, is not her health, are not her limbs more valuable than panes of glass? There is no doubt of that, but most important of all, does not the breaking of glass produce more effect upon the Government? If you are fighting a battle, that should dictate your choice of weapons. Well, then, we are going to try this time if mere stones will do it. I do not think it will ever be necessary for us to arm ourselves as Chinese women have done, but there are women who are prepared to do that if it should be necessary. In this Union we don't lose our heads. We only go as far as we are obliged to go in order to win, and we are going forward with this next protest demonstration in full faith that this plan of campaign, initiated by our friends whom we honour to-night, will on this next occasion prove effective."

Ever since militancy took on the form of destruction of property the public generally, both at home and abroad, has expressed curiosity as to the logical connection between acts such as breaking windows, firing pillar boxes, et cetera, and the vote. Only a complete lack of historical knowledge excuses that curiosity. For every advance of men's political freedom has been marked with violence and the destruction of property. Usually the advance has been marked by war, which is called glorious. Sometimes it has been marked by riotings, which are deemed less glorious but are at least effective. That speech of mine, just quoted, will probably strike the reader as one inciting to violence and illegal action, things as a rule and in ordinary circumstances quite inexcusable. Well, I will call the reader's attention to what was, in this connection, a rather singular coincidence. At the very hour when I was making that speech, advising my audience of the political necessity of physical revolt, a responsible member of the Government, in another hall, in another city, was telling his audience precisely the same thing. This Cabinet Minister, the right Honourable C. E. H. Hobhouse, addressing a large anti-suffrage meeting in his constituency of Bristol, said that the suffrage movement was not a

political issue because its adherents had failed to prove that behind this movement existed a large public demand. He declared that "In the case of the suffrage demand there has not been the kind of popular sentimental uprising which accounted for Nottingham Castle in 1832 or the Hyde Park railings in 1867. There has not been a great ebullition of popular feeling."

The "popular sentimental uprising" to which Mr. Hobhouse alluded was the burning to the ground of the castle of the anti-suffrage Duke of Newcastle, and of Colwick Castle, the country seat of another of the leaders of the opposition against the franchise bill. The militant men of that time did not select uninhabited buildings to be fired. They burned both these historic residences over their owners' heads. Indeed, the wife of the owner of Colwick Castle died as a result of shock and exposure on that occasion. No arrests were made, no men imprisoned. On the contrary the King sent for the Premier, and begged the Whig Ministers favourable to the franchise bill not to resign, and intimated that this was also the wish of the Lords who had thrown out the bill. Molesworth's History of England says:

These declarations were imperatively called for. The danger was imminent and the Ministers knew it and did all that lay in their power to tranquillise the people, and to assure them that the bill was only delayed and not finally defeated.

For a time the people believed this, but soon they lost patience, and seeing signs of a renewed activity on the part of the anti-suffragists, they became aggressive again. Bristol, the very city in which Mr. Hobhouse made his speech, was set on fire. The militant reformers burned the new gaol, the toll houses, the Bishop's Palace, both sides of Queen's Square, including the Mansion House, the custom house, the excise office, many warehouses, and other private property, the whole valued at over L100,000--five hundred thousand dollars. It was as a result of such violence, and in fear of more violence, that the reform bill was hurried through Parliament and became law in June, 1832.

Our demonstration, so mild by comparison with English men's political agitation, was announced for March 4th, and the announcement created much public alarm. Sir William Byles gave notice that he would "ask the Secretary of State for the Home Department whether his attention had been drawn to a speech by Mrs. Pankhurst last Friday night, openly and emphatically inciting her hearers to violent outrage and the destruction of property, and threatening the use of firearms if stones did not prove sufficiently effective; and what steps he proposes to take to protect Society from this outbreak of lawlessness."

The question was duly asked, and the Home Secretary replied that his attention had been called to the speech, but that it would not be desirable in the public interest to say more than this at present.

Whatever preparations the police department were making to prevent the demonstration, they failed because, while as usual, we were able to calculate exactly what the police department were going to do, they were utterly unable to calculate what we were going to do. We had planned a demonstration for March 4th, and this one we announced. We planned another demonstration for March 1st, but this one we did not announce. Late in the afternoon of Friday, March 1st, I drove in a taxicab, accompanied by the Hon. Secretary of the Union, Mrs. Tuke and another of our members, to No. 10 Downing Street, the official residence of the Prime Minister. It was exactly half past five when we alighted from the cab and threw our stones, four of them, through the window panes. As we expected we were promptly arrested and taken to Cannon Row police station. The hour that followed will long be remembered in London. At intervals of fifteen minutes relays of women who had volunteered for the demonstration did their work. The first smashing of glass occurred in the Haymarket and Piccadilly, and greatly startled and alarmed both pedestrians and police. A large number of the women were arrested, and everybody thought that this ended the affair. But before the excited populace and the frustrated shop owners' first exclamation had died down, before the police had reached the station with their prisoners, the ominous crashing and splintering of plate glass began again, this time along both sides of Regent Street and the Strand. A furious rush of police and people towards the second scene of action ensued. While their attention was being taken up with occurrences in this quarter, the third relay of women began breaking the windows in Oxford Circus and Bond Street. The demonstration ended for the day at half past six with the breaking of many windows in the Strand. The _Daily Mail_ gave this graphic account of the demonstration:

From every part of the crowded and brilliantly lighted streets came the crash of splintered glass. People started as a window shattered at their side; suddenly there was another crash in front of them; on the other side of the street; behind--everywhere. Scared shop assistants came running out to the pavements; traffic stopped; policemen sprang this way and that; five minutes later the streets were a procession of excited groups, each surrounding a woman wrecker being led in custody to the nearest police station. Meanwhile the shopping quarter of London had plunged itself into a sudden twilight. Shutters were hurriedly fitted; the rattle of iron curtains being drawn came from every side. Guards of commissionaires and shopmen were quickly mounted, and any

unaccompanied lady in sight, especially if she carried a hand bag, became an object of menacing suspicion.

At the hour when this demonstration was being made a conference was being held at Scotland Yard to determine what should be done to prevent the smashing of windows on the coming Monday night. But we had not announced the hour of our March 4th protest. I had in my speech simply invited women to assemble in Parliament Square on the evening of March 4th, and they accepted the invitation. Said the _Daily Telegraph_:

By six o'clock the neighbourhood Houses of Parliament were in a stage of siege. Shop keepers in almost every instance barricaded their premises, removed goods from the windows and prepared for the worst. A few minutes before six o'clock a huge force of police, amounting to nearly three thousand constables, was posted in Parliament Square, Whitehall, and streets adjoining, and large reserves were gathered in Westminster Hall and Scotland Yard. By half past eight Whitehall was packed from end to end with police and public. Mounted constables rode up and down Whitehall keeping the people on the move. At no time was there any sign of danger....

The demonstration had taken place in the morning, when a hundred or more women walked quietly into Knightsbridge and walking singly along the streets demolished nearly every pane of glass they passed. Taken by surprise the police arrested as many as they could reach, but most of the women escaped.

[Illustration: THE ARGUMENT OF THE BROKEN WINDOW PANE]

For that two days' work something like two hundred suffragettes were taken to the various police stations, and for days the long procession of women streamed through the courts. The dismayed magistrates found themselves facing, not only former rebels, but many new ones, in some cases, women whose names, like that of Dr. Ethel Smyth, the composer, were famous throughout Europe. These women, when arraigned, made clear and lucid statements of their positions and their motives, but magistrates are not schooled to examine motives. They are trained to think only of laws and mostly of laws protecting property. Their ears are not tuned to listen to words like those spoken by one of the prisoners, who said: "We have tried every means--processions and meetings--which were of no avail. We have tried demonstrations, and now at last we have to break windows. I wish I had broken more. I am not in the least repentant. Our women are working in far worse condition than the striking miners. I have seen widows struggling to bring up their children. Only two out of every five are fit to be soldiers. What is the good of a country like ours? England is absolutely on the wane. You only have one point of view, and that is the men's, and while men have done the best they could, they cannot go far without the women and the women's views. We believe the whole is in a muddle too horrible to think of."

The coal miners were at that time engaging in a terrible strike, and the Government, instead of arresting the leaders, were trying to come to terms of peace with them. I reminded the magistrate of this fact, and I told him that what the women had done was but a fleabite by comparison with the miners' violence. I said further: "I hope our demonstration will be enough to show the Government that the women's agitation is going on. If not, if you send me to prison, I will go further to show that women who have to help pay the salaries of Cabinet Ministers, and your salary too, sir, are going to have some voice in the making of the laws they have to obey."

I was sentenced to two months' imprisonment. Others received sentences ranging from one week to two months, while those who were accused of breaking glass above five pounds in value, were committed for trial in higher courts. They were sent to prison on remand, and when the last of us were behind the grim gates, not only Holloway but three other women's prisons were taxed to provide for so many extra inmates.

It was a stormy imprisonment for most of us. A great many of the women had received, in addition to their sentences, "hard labour," and this meant that the privileges at that time accorded to Suffragettes, as political offenders, were withheld. The women adopted the hunger strike as a protest, but as the hint was conveyed to me that the privileges would be restored, I advised a cessation of the strike. The remand prisoners demanded that I be allowed to exercise with them, and when this was not answered they broke the windows of their cells. The other suffrage prisoners, hearing the sound of shattered glass, and the singing of the Marseillaise, immediately broke their windows. The time had long gone by when the Suffragettes submitted meekly to prison discipline. And so passed the first days of my imprisonment.

CHAPTER II

The panic stricken Government did not rest content with the imprisonment of the window breakers. They sought, in a blind and blundering fashion, to perform the impossible feat of wrecking at a blow the entire militant movement. Governments have always tried to crush reform movements, to destroy ideas, to kill the thing that cannot die. Without regard to history, which shows that no Government have ever succeeded in doing this, they go on trying in the old, senseless way.

For days before the two demonstrations described in the last chapter our headquarters in Clement's Inn had been under constant observation by the police, and on the evening of March 5th an inspector of police and a large force of detectives suddenly descended on the place, with warrants for the arrest of Christabel Pankhurst and Mr. and Mrs. Pethick Lawrence, who with Mrs. Tuke and myself were charged with "conspiring to incite certain persons to commit malicious damage to property." When the officers entered they found Mr. Pethick Lawrence at work in his office, and Mrs. Pethick Lawrence in her flat upstairs. My daughter was not in the building. The Lawrences, after making brief preparations drove in a taxicab to Bow Street Station, where they spent the night. The police remained in possession of the offices, and detectives were despatched to find and arrest Christabel. But that arrest never took place. Christabel Pankhurst eluded the entire force of detectives and uniformed police, trained hunters of human prey.

Christabel had gone home, and at first, on hearing of the arrest of Mr. and Mrs. Pethick Lawrence, had taken her own arrest for granted. A little reflection however showed her the danger in which the Union would stand if completely deprived of its accustomed leadership, and seeing that it was her duty to avoid arrest, she quietly left the house. She spent that night with friends who, next morning, helped her to make the necessary arrangements and saw her safely away from London. The same night she reached Paris, where she has since remained. My relief, when I learned of her flight, was very great, because I knew that whatever happened to the Lawrences and myself, the movement would be wisely directed, this in spite of the fact that the police remained in full possession of headquarters.

The offices in Clement's Inn were thoroughly ransacked by the police, in a determined effort to secure evidence of conspiracy. They went through every desk, file and cabinet, taking away with them two cab loads of books and papers, including all my private papers, photographs of my children in infancy, and letters sent me by my husband long ago. Some of these I never saw again.

The police also terrorised the printer of our weekly newspaper, and although the paper came out as usual, about a third of its columns were left blank. The headlines, however, with the ensuing space mere white paper produced a most dramatic effect. "History Teaches" read one headline to a blank space, plainly indicating that the Government were not willing to let the public know some of the things that history teaches. "Women's Moderation" suggested that the destroyed paragraph called for comparison of the women's window breaking with men's greater violence in the past. Most eloquent of all was the editorial page, absolutely blank except for the headline, "A Challenge!" and the name at the foot of the last column, Christabel Pankhurst. What words could have breathed a prouder defiance, a more implacable resolve? Christabel was gone, out of the clutches of the Government, yet she remained in complete possession of the field. For weeks the search for her went relentlessly on. Police searched every railway station, every train, every sea port. The police of every city in the Kingdom were furnished with her portrait. Every amateur Sherlock Holmes in England joined with the police in finding her. She was reported in a dozen cities, including New York. But all the time she was living quietly in Paris, in daily communication with the workers in London, who within a few days were once more at their appointed tasks. My daughter has remained in France ever since.

Meanwhile, I found myself in the anomalous position of a convicted offender serving two months' prison sentence, and of a prisoner on remand waiting to be charged with a more serious offence. I was in very bad health, having been placed in a damp and unwarmed third division cell, the result being an acute attack of bronchitis. I addressed a letter to the Home Secretary, telling him of my condition, and urging the necessity of liberty to recover my health and to prepare my case for trial. I asked for release on bail, the plain right of a remand prisoner, and I offered if bail were granted now to serve the rest of my two months' sentence later on. The sole concessions granted me, however, were removal to a better cell and the right to see my secretary and my solicitor, but only in the presence of a wardress and a member of the prison clerical staff. On March 14th Mr. and Mrs. Pethick Lawrence, Mrs. Tuke and myself were brought up for preliminary hearing on the charge of having, on November 1, 1911, and on various other dates "conspired and combined together unlawfully and maliciously to commit damage, etc." The case opened on March 14th in a crowded courtroom in which I saw many friends. Mr. Bodkin, who appeared for the prosecution, made a very long address, in which he endeavoured to prove that the Women's Social and Political Union was a highly developed organisation of most sinister character. He produced much documentary evidence, some of it of such amusing character that the court rocked with stifled laughter, and the judge was obliged to conceal his smiles behind his hand. Mr. Bodkin cited our code book with the assistance of which we were able to communicate private messages. His voice sank to a scandalised half whisper as he stated the fact that we

had presumed to include the sacred persons of the Government in our private code. "We find," said Mr. Bodkin portentously, "that public men in the service of His Majesty as members of the Cabinet are tabulated here under code names. We find that the Cabinet collectively has its code word "Trees," and individual members of the Cabinet are designated by the name, sometimes of trees, but I am also bound to say the commonest weeds as well." Here a ripple of laughter interrupted. Mr. Bodkin frowned heavily, and continued: "There is one," he said solemnly, "called Pansy; another one--more complimentary--Roses, another, Violets, and so on." Each of the defendants was designated by a code letter. Thus Mrs. Pankhurst was identified by the letter F; Mrs. Pethick Lawrence, D; Miss Christabel Pankhurst, E. Every public building, including the House of Commons, had its code name. The deadly possibilities of the code were illustrated by a telegram found in one of the files. It read: "Silk, thistle, pansy, duck, wool, E. Q." Translated by the aid of the code book the telegram read: "Will you protest Asquith's public meeting to-morrow evening but don't get arrested unless success depends on it. Wire back to Christabel Pankhurst, Clements Inn."

More laughter followed these revelations, which after all proved no more than the business-like methods employed by the W. S. P. U. The laughter proved something a great deal more significant, for it was a plain indication that the old respect in which Cabinet Ministers had been held was no more. We had torn the veil from their sacro-sanct personalities and shown them for what they were, mean and scheming politicians. More serious from the point of view of prosecution was the evidence brought in by members of the police department in regard to the occurrences of March 1st and 4th. The policemen who arrested me and my two companions in Downing Street on March 1st, after we had broken the windows in the Premier's house, testified that following the arrest, we had handed him our reserve stock of stones, and that they were all alike, heavy flints. Other prisoners were found in possession of similar stones, tending to prove that the stones all came from one source. Other officers testified to the methodical manner in which the window breaking of March 1st and 4th was carried out, how systematically it had been planned and how soldierly had been the behaviour of the women. By twos and threes March 4th they had been seen to go to the headquarters at Clement's Inn, carrying handbags, which they deposited at headquarters, and had then gone on to a meeting at the Pavillion Music Hall. The police attended the meeting, which was the usual rally preceding a demonstration or a deputation. At five o'clock the meeting adjourned and the women went out, as if to go home. The police observed that many of them, still in groups of twos and threes, went to the Gardenia restaurant in Catherine Street, Strand, a place where many Suffragette breakfasts and teas had been held. The police thought that about one hundred and fifty women congregated there on March 4th. They remained until seven o'clock, and then, under the watching eyes of the police, they sauntered out and dispersed. A few minutes later, when there was no reason to expect such a thing, the noise was heard, in many streets, of wholesale window smashing. The police authorities made much of the fact that the women who had left their bags at headquarters and were afterwards arrested, were bailed out that night by Mr. Pethick Lawrence. The similarity of the stones used; the gathering of so many women in one building, prepared for arrest; the waiting at the Gardenia Restaurant; the apparent dispersal; the simultaneous destruction in many localities of plate glass, and the bailing of prisoners by a person connected with the headquarters mentioned, certainly showed a carefully worked out plan. Only a public trial of the defendants could establish whether or not the plan was a conspiracy.

On the second day of the Ministerial hearing, Mrs. Tuke, who had been in the prison infirmary for twenty days and had to be attended in court by a trained nurse, was admitted to bail. Mr. Pethick Lawrence made a strong plea for bail for himself and his wife, pointing out that they had been in prison on remand for two weeks and were entitled to bail. I also demanded the privileges of a prisoner on remand. Both of these pleas were denied by the court, but a few days later the Home Secretary wrote to my solicitor that the remainder of my sentence of two months would be remitted until after the conspiracy trail at Bow Street. Mr. and Mrs. Pethick Lawrence had already been admitted to bail. Public opinion forced the Home Secretary to make these concessions, as it is well known that it is next to impossible to prepare a defence while confined in prison. Aside from the terrible effect of prison on one's body and nerves, there is the difficulty of consulting documents and securing other necessary data to be considered.

On April 4th the Ministerial hearing ended in the acquittal of Mrs. Tuke, whose activities in the W. S. P. U. were shown to be purely secretarial. Mr. and Mrs. Pethick Lawrence and myself were committed for trial at the next session of the Central Criminal Court, beginning April 23rd. Because of the weak state of my health the judge was with great difficulty prevailed upon to postpone the trial two weeks and it was, therefore, not until May 15th that the case was opened.

The trial at Old Bailey is a thing that I shall never forget. The scene is clear before me as I write, the judge impressively bewigged and scarlet robed, dominating the crowded courtroom, the solicitors at their table, the jury, and looking very far away, the anxious pale faces of our friends who crowded the narrow galleries.

By the veriest irony of fate this judge, Lord Coleridge, was the son of Sir Charles Coleridge who, in the year 1867, appeared with my husband, Dr. Pankhurst, in the famous case of Chorlton v. Lings, and sought to establish that women were persons, and as

such were entitled to the Parliamentary vote. To make the irony still deeper the Attorney General, Sir Rufus Isaacs, who appeared as Counsel for the prosecution against women militants, himself had been guilty of remarkable speeches in corroboration of our point of view. In a speech made in 1910, in relation to the abolition of the Lords' veto, Sir Rufus made the statement that, although the agitation against privilege was being peacefully conducted, the indignation behind it was very intense. Said Sir Rufus: "Formerly when the great mass of the people were voteless they had to do something violent in order to show what they felt; to-day the elector's bullet is his ballot. Let no one be deceived, therefore, because in this present struggle everything is peaceful and orderly, in contrast to the disorderliness of other great struggles of the past." We wondered if the man who said these words could fail to realise that voteless women, deprived of every constitutional means of righting their grievances, were also obliged to do something violent in order to show how they felt. His opening address removed all doubt on that score.

Sir Rufus Isaacs has a clear-cut, hawk-like face, deep eyes, and a somewhat world worn air. The first words he spoke were so astoundingly unfair that I could hardly believe that I heard them aright. He began his address to the jury by telling them that they must not, on any account, connect the act of the defendants with any political agitation.

"I am very anxious to impress upon you," he said, "from the moment we begin to deal with the facts of this case, that all questions of whether a woman is entitled to the Parliamentary franchise, whether she should have the same right of franchise as a man, are questions which are in no sense involved in the trial of this issue.... Therefore, I ask you to discard altogether from the consideration of the matters which will be placed before you any viewpoint you may have on this no doubt very important political issue."

Nevertheless Sir Rufus added in the course of his remarks that he feared that it would not be possible to keep out of the conduct of the case various references to political events, and of course the entire trial, from beginning to end, showed clearly that the case was what Mr. Tim Healey, Mrs. Pethick Lawrence's counsel, called it, a great State Trial.

Proceeding, the Attorney General described the W. S. P. U., which he said he thought had been in existence since 1907, and had used what were known as militant methods. In 1911 the association had become annoyed by the Prime Minister because he would not make women's suffrage what was called a Government question. In November, 1911, the Prime Minister announced the introduction of a manhood suffrage bill. From that time on the defendants set to work to carry out a campaign which would have meant nothing less than anarchy. Women were to be induced to act together at a given time, in different given places, in such numbers that the police should be paralysed by the number of persons breaking the law, in order, to use the defendant's own words, "to bring the Government to its knees."

After designating the respective positions held by the four defendants in the W. S. P. U., Sir Rufus went on to relate the events which resulted in the smashing of plate glass windows valued at some two thousand pounds, and the imprisonment of over two hundred women who were incited to their deeds by the conspirators in the dock. He entirely ignored the motive of the acts in question, and he treated the whole affair as if the women had been burglars. This inverted statement of the matter, though accurate enough as to facts, was such as might have been given by King John of the signing of Magna Charta.

A very great number of witnesses were examined, a large number of them being policemen, and their testimony, and our cross examination disclosed the startling fact that there exists in England a special band of secret police entirely engaged in political work. These men, seventy-five in number, form what is known as the political branch of the Criminal Investigation Department of the Police. They go about in disguise, and their sole duty is to shadow Suffragettes and other political workers. They follow certain political workers from their homes to their places of business, to their social pleasures, into tea rooms and restaurants, even to the theatre. They pursue unsuspecting people in taxicabs, sit beside them in omnibuses. Above all they take down speeches. In fact the system is exactly like the secret police system of Russia.

Mr. Pethick Lawrence and I spoke in our own defence, and Mr. Healey M. P. defended Mrs. Pethick Lawrence. I cannot give our speeches in full, but I should like to include as much of them as will serve to make the entire situation clear to the reader.

Mr. Lawrence spoke first at the opening of the case. He began by giving an account of the suffrage movement and why he felt the enfranchisement of women appeared to him a question so grave that it warranted strong measures in its pursuit. He sketched briefly the history of the Women's Social and Political Union, from the time when Christabel Pankhurst and Annie Kenney were thrown out of Sir Edward Grey's meeting and imprisoned for asking a political question, to the torpedoing of the Conciliation Bill. "The case that I have to put before you," he said, "is that neither the conspiracy nor the incitement is ours; but that the conspiracy is a conspiracy of the Cabinet who are responsible for the Government of this country; and that the incitement is the incitement of the Ministers of the Crown." And he did this most effectually not only by telling of the disgraceful trickery and deceit with which the

Government had misled the suffragists in the matter of suffrage bills, but by giving the plain words in which members of the Cabinet had advised the women that they would never get the vote until they had learned to fight for it as men had fought in the past.

When it came my turn to speak, realising that the average man is profoundly ignorant of the history of the women's movement--because the press has never adequately or truthfully chronicled the movement--I told the jury, as briefly as I could, the story of the forty years' peaceful agitation before my daughters and I resolved that we would give our lives to the work of getting the vote for women, and that we should use whatever means of getting the vote that were necessary to success.

"We founded the Women's Social and Political Union," I said, "in 1903. Our first intention was to try and influence the particular political Party, which was then coming into power, to make this question of the enfranchisement of women their own question and to push it. It took some little time to convince us--and I need not weary you with the history of all that has happened--but it took some little time to convince us that that was no use; that we could not secure things in that way. Then in 1905 we faced the hard facts. We realised that there was a Press boycott against Women's Suffrage. Our speeches at public meetings were not reported, our letters to the editors, were not published, even if we implored the editors; even the things relating to Women's Suffrage in Parliament were not recorded. They said the subject was not of sufficient public interest to be reported in the Press, and they were not prepared to report it. Then with regard to the men politicians in 1905: we realised how shadowy were the fine phrases about democracy, about human equality, used by the gentlemen who were then coming into power. They meant to ignore the women--there was no doubt whatever about that. For in the official documents coming from the Liberal party on the eve of the 1905 election, there were sentences like this: 'What the country wants is a simple measure of Manhood Suffrage.' There was no room for the inclusion of women. We knew perfectly well that if there was to be franchise reform at all, the Liberal party which was then coming into power did not mean Votes for Women, in spite of all the pledges of members; in spite of the fact that a majority of the House of Commons, especially on the Liberal side, were pledged to it--it did not mean that they were going to put it into practice. And so we found some way of forcing their attention to this question.

"Now I come to the facts with regard to militancy. We realised that the plans we had in our minds would involve great sacrifice on our part, that it might cost us all we had. We were at that time a little organisation, composed in the main of working women, the wives and daughters of working men. And my daughters and I took a leading part, naturally, because we thought the thing out, and, to a certain extent, because we were of better social position than most of our members, and we felt a sense of responsibility."

I described the events that marked the first days of our work, the scene in Free Trade Hall, Manchester, when my daughter and her companion were arrested for the crime of asking a question of a politician, and I continued:

"What did they do next? (I want you to realise that no step we have taken forward has been taken until after some act of repression on the part of our enemy, the Government--because it is the Government that is our enemy; it is not the Members of Parliament, it is not the men in the country; it is the Government in power alone that can give us the vote. It is the Government alone that we regard as our enemy, and the whole of our agitation is directed to bringing just as much pressure as necessary upon those people who can deal with our grievance.) The next step the women took was to ask questions during the course of meetings, because, as I told you, these gentlemen gave them no opportunity of asking them afterwards. And then began the interjections of which we have heard, the interference with the right to hold public meetings, the interference with the right of free speech, of which we have heard, for which these women, these hooligan women, as they have been called--have been denounced. I ask you, gentlemen, to imagine the amount of courage which it needs for a woman to undertake that kind of work. When men come to interrupt women's meetings, they come in gangs, with noisy instruments, and sing and shout together, and stamp their feet. But when women have gone to Cabinet Ministers' meetings--only to interrupt Cabinet Ministers and nobody else--they have gone singly. And it has become increasingly difficult for them to get in, because as a result of the women's methods there has developed the system of admission by ticket and the exclusion of women--a thing which in my Liberal days would have been thought a very disgraceful thing at Liberal meetings. But this ticket system developed, and so the women could only get in with very great difficulty. Women have concealed themselves for thirty-six hours in dangerous positions, under the platforms, in the organs, wherever they could get a vantage point. They waited starving in the cold, sometimes on the roof exposed to a winter's night, just to get a chance of saying in the course of a Cabinet Minister's speech, 'When is the Liberal Government going to put its promises into practice?' That has been the form militancy took in its further development."

I went over the whole matter of our peaceful deputations, and of the violence with which they were invariably met; of our arrests and the farcical police court trials, where the mere evidence of policemen's unsupported statements sent us to prison for long terms; of the falsehoods told of us in the House of Commons by responsible members of the Government--tales of women scratching and

biting policemen and using hatpins--and I accused the Government of making these attacks against women who were powerless to defend themselves because they feared the women and desired to crush the agitation represented by our organisation.

"Now it has been stated in this Court," I said, "that it is not the Women's Social and Political Union that is in the Court, but that it is certain defendants. The action of the Government, gentlemen, is certainly against the defendants who are before you here to-day, but it is also against the Women's Social and Political Union. The intention is to crush that organisation. And this intention apparently was arrived at after I had been sent to prison for two months for breaking a pane of glass worth, I am told, 2s. 3d., the punishment which I accepted because I was a leader of this movement, though it was an extraordinary punishment to inflict for so small an act of damages as I had committed. I accepted it as the punishment for a leader of an agitation disagreeable to the Government; and while I was there this prosecution started. They thought they would make a clean sweep of the people who they considered were the political brains of the movement. We have got many false friends in the Cabinet--people who by their words appear to be well-meaning towards the cause of Women's Suffrage. And they thought that if they could get the leaders of the Union out of the way, it would result in the indefinite postponement and settlement of the question in this country. Well, they have not succeeded in their design, and even if they had got all the so-called leaders of this movement out of their way they would not have succeeded even then. Now why have they not put the Union in the dock? We have a democratic Government, so-called. This Women's Social and Political Union is not a collection of hysterical and unimportant wild women, as has been suggested to you, but it is an important organisation, which numbers amongst its membership very important people. It is composed of women of all classes of the community, women who have influence in their particular organisations as working women; women who have influence in professional organisations as professional women; women of social importance; women even of Royal rank are amongst the members of this organisation, and so it would not pay a democratic Government to deal with this organisation as a whole.

"They hoped that by taking away the people that they thought guided the political fortunes of the organisation they would break the organisation down. They thought that if they put out of the way the influential members of the organisation they, as one member of the Cabinet, I believe, said, would crush the movement and get it 'on the run.' Well, Governments have many times been mistaken, gentlemen, and I venture to suggest to you that Governments are mistaken again. I think the answer to the Government was given at the Albert Hall meeting held immediately after our arrest. Within a few minutes, without the eloquence of Mrs. Pethick Lawrence, without the appeals of the people who have been called the leaders of this movement, in a very few minutes L10,000 was subscribed for the carrying on of this movement.

"Now a movement like that, supported like that, is not a wild, hysterical movement. It is not a movement of misguided people. It is a very serious movement. Women, I submit, like our members, and women, I venture to say, like the two women, and like the man who are in the dock to-day, are not people to undertake a thing like this lightly. May I just try to make you feel what it is that has made this movement the gigantic size it is from the very small beginnings it had? It is one of the biggest movements of modern times. A movement which is not only an influence, perhaps not yet recognised, in this country, but is influencing the women's movement all over the world. Is there anything more marvellous in modern times than the kind of spontaneous outburst in every country of this woman's movement? Even in China--and I think it somewhat of a disgrace to Englishmen--even in China women have won the vote, as an outcome of a successful revolution, with which, I dare say, members of his Majesty's Government sympathise--a bloody revolution.

"One more word on that point. When I was in prison the second time, for three months as a common criminal for no greater offence than the issue of a handbill--less inflammatory in its terms than some of the speeches of members of the Government who prosecute us here--during that time, through the efforts of a member of Parliament, there was secured for me permission to have the daily paper in prison, and the first thing I read in the daily Press was this: that the Government was at that moment feting the members of the Young Turkish Revolutionary Party, gentlemen who had invaded the privacy of the Sultan's home--we used to hear a great deal about invading the privacy of Mr. Asquith's residence when we ventured to ring his door bell--gentlemen who had killed and slain, and had been successful in their revolution, while we women had never thrown a stone--for none of us was imprisoned for stone throwing, but merely for taking the part we had then taken in this organisation. There we were imprisoned while these political murderers were being feted by the very Government who imprisoned us, and were being congratulated on the success of their revolution. Now I ask you, was it to be wondered at that women said to themselves: 'Perhaps it is that we have not done enough. Perhaps it is that these gentlemen do not understand womenfolk. Perhaps they do not realise women's ways, and because we have not done the things that men have done, they may think we are not in earnest.'

"And then we come down to this last business of all, when we have responsible statesmen like Mr. Hobhouse saying that there had never been any sentimental uprising, no expression of feeling like that which led to the burning down of Nottingham Castle. Can you wonder, then, that we decided we should have to nerve ourselves to do more, and can you understand why we cast about to find a way, as women will, that would not involve loss of human life and the maiming of human beings, because women care more about human life than men, and I think it is quite natural that we should, for we know what life costs. We risk our lives when men are born. Now, I want to say this deliberately as a leader of this movement. We have tried to hold it back, we have tried to keep it from going beyond bounds, and I have never felt a prouder woman than I did one night when a police constable said to me, after one of these demonstrations, 'Had this been a man's demonstration, there would have been bloodshed long ago.' Well, my lord, there has not been any bloodshed except on the part of the women themselves--these so-called militant women. Violence has been done to us, and I who stand before you in this dock have lost a dear sister in the course of this agitation. She died within three days of coming out of prison, a little more than a year ago. These are things which, wherever we are, we do not say very much about. We cannot keep cheery, we cannot keep cheerful, we cannot keep the right kind of spirit, which means success, if we dwell too much upon the hard part of our agitation. But I do say this, gentlemen, that whatever in future you may think of us, you will say this about us, that whatever our enemies may say, we have always put up an honourable fight, and taken no unfair means of defeating our opponents, although they have not always been people who have acted so honourably towards us.

"We have assaulted no one; we have done no hurt to any one; and it was not until 'Black Friday'--and what happened on 'Black Friday' is that we had a new Home Secretary, and there appeared to be new orders given to the police, because the police on that occasion showed a kind of ferocity in dealing with the women that they had never done before, and the women came to us and said: 'We cannot bear this'--it was not until then we felt this new form of repression should compel us to take another step. That is the question of 'Black Friday,' and I want to say here and now that every effort was made after 'Black Friday' to get an open public judicial inquiry into the doings of 'Black Friday,' as to the instructions given to the police. That inquiry was refused; but an informal inquiry was held by a man, whose name will carry conviction as to his status and moral integrity on the one side of the great political parties, and a man of equal standing on the Liberal side. These two men were Lord Robert Cecil and Mr. Ellis Griffith. They held a private inquiry, had women before them, took their evidence, examined that evidence, and after hearing it said that they believed what the women had told them was substantially true, and that they thought there was good cause for that inquiry to be held. That was embodied in a report. To show you our difficulties, Lord Robert Cecil, in a speech at the Criterion Restaurant, spoke on this question. He called upon the Government to hold this inquiry, and not one word of that speech was reported in any morning paper. That is the sort of thing we have had to face, and I welcome standing here, if only for the purpose of getting these facts out, and I challenge the Attorney General to institute an inquiry into these proceedings--not that kind of inquiry of sending their inspectors to Holloway and accepting what they are told by the officials--but to open a public inquiry, with a jury, if he likes, to deal with our grievances against the Government and the methods of this agitation.

"I say it is not the defendants who have conspired, but the Government who have conspired against us to crush this agitation; but however the matter may be decided, we are content to abide by the verdict of posterity. We are not the kind of people who like to brag a lot; we are not the kind of people who would bring ourselves into this position unless we were convinced that it was the only way. I have tried--all my life I have worked for this question--I have tried arguments, I have tried persuasion. I have addressed a greater number of public meetings, perhaps, than any person in this court, and I have never addressed one meeting where substantially the opinion of the meeting--not a ticket meeting, but an open meeting, for I have never addressed any other kind of a meeting--has not been that where women bear burdens and share responsibilities like men they should be given the privileges that men enjoy. I am convinced that public opinion is with us--that it has been stifled--wilfully stifled--so that in a public Court of Justice one is glad of being allowed to speak on this question."

The Attorney General's summing up for the prosecution was very largely a defence of the Liberal Party and its course in regard to woman suffrage legislation. Therefore, Mr. Tim Healey, in his defence of Mrs. Pethick Lawrence, did well to lay stress on the political character of the conspiracy charge and trial. He said:

"It is no doubt a very useful thing when you have political opponents to be able to set the law in motion against them. I have not the smallest doubt it would be a very convenient thing, if they had the courage to do it, to shut up the whole of His Majesty's Opposition while the present Government is in office--to lock up all the men of lustre and distinction in our public forum and on our public platforms--all the Carsons, F. E. Smiths, Bonar Laws, and so on. It would be a most convenient thing to end the whole thing, as it would be to end women's agitation in the form of the indictment. Gentlemen of the jury, whatever words have been spoken by mutual opponents, whatever instructions have been addressed, not to feeble females, but to men who boast of drilling and of arms,

they have not had the courage to prosecute anybody, except women, by means of an indictment. Yet the Government of my learned friend have selected two dates as cardinal dates, and they ask you to pass judgment upon the prisoners at the bar, and to say that, without rhyme or reason, taking the course suggested without provocation, these responsible, well-bred, educated, University people, have suddenly, in the words of the indictment, wickedly and with malice aforethought engaged in these criminal designs.

"Gentlemen of the jury, the first thing I would ask in that connection is this: What is there in the course of this demand put forward by women which should have excited the treatment at the hands of His Majesty's Ministers which this movement, according to the documents which are in evidence before me, has received? I should suppose that the essence of all government is the smooth conduct of affairs, so that those who enjoy high station, great emoluments, should not be parties against whom the accusation of provoking civic strife and breeding public turmoil should be brought. What do we find? We find that, in regard to the treatment of the demand which had always been put forward humbly, respectably, respectfully, in its origin, by those who have received trade unionists, anti-vaccinators, deceased wife's sisters, and all other forms of political demand, and who have received them humbly and yielded to them, we find that when these people advocating this particular form of civic reform request an audience, request admission, request even to have their petitions respectfully received, they have met, judicially, at all events, with a flat and solemn negative. That is the beginning of this unhappy spirit bred in the minds of persons like the defendants, persons like those against whom evidence has been tendered--which has led to your being empanelled in that box to-day. And I put it to you when you are considering whether it is the incitement of my clients or the conduct of Ministers that have led to these events--whether I cannot ask you to say that even a fair apportionment of blame should not rest upon more responsible shoulders, and whether you should go out of your way to say that these persons in the dock alone are guilty."

In closing Mr. Healey reverted to the political character of the trial. "The Government have undertaken this prosecution," he declared, "to seclude for a considerable period their chief opponents. They hope there will be at public meetings which they attend no more inconvenient cries of 'Votes for Women.' I cannot conceive any other object which they could have in bringing the prosecution. I have expressed my regret at the loss which the shopkeepers, tradesmen and others have suffered. I regret it deeply. I regret that any person should bring loss or suffering upon innocent people. But I ask you to say that the law has already been sufficiently vindicated by the punishment of the immediate authors of the deed. What can be gained? Does justice gain?

"I almost hesitate to treat this as a legal inquiry. I regard it as a vindictive political act. Of all the astonishing acts that have ever been brought into a public court against a prisoner I cannot help feeling the charge against Mr. Pethick Lawrence is the most astonishing. He ventured to attend at some police courts and gave bail for women who had been arrested in endeavouring, as I understand, to present petitions to Parliament or to have resort to violence. I do not complain of the way in which my learned friend has conducted the prosecution, but I do complain of the police methods--inquiring into the homes and the domestic circumstances of the prisoners, obtaining their papers, taking their newspaper, going into their banking account, bringing up their bankers here to say what is their balance; and I do say that in none of the prosecutions of the past have smaller methods belittled a great State trial, because, look at it as you will, you cannot get away from it that this is a great State trial. It is not the women who are on trial. It is the men. It is the system of Government which is upon its trial. It is this method of rolling the dice by fifty-four counts in an indictment without showing to what any bit of evidence is fairly attributable; the system is on its trial--a system whereby every innocent act in public life is sought to be enmeshed in a conspiracy."

The jury was absent for more than an hour, showing that they had some difficulty in agreeing upon a verdict. When they returned it was plain from their strained countenances that they were labouring under deep feeling. The foreman's voice shook as he pronounced the verdict, guilty as charged, and he had hard work to control his emotion as he added: "Your Lordship, we unanimously desire to express the hope that, taking into consideration the undoubtedly pure motives that underlie the agitation that has led to this trouble, you will be pleased to exercise the utmost clemency and leniency in dealing with the case."

A burst of applause followed this plea. Then Mr. Pethick Lawrence arose and asked to say a few words before sentence was pronounced. He said that it must be evident, aside from the jury's recommendation, that we had been actuated by political motives, and that we were in fact political offenders. It had been decided in English Courts that political offenders were different from ordinary offenders, and Mr. Lawrence cited the case of a Swiss subject whose extradition was refused because of the political character of his offence. The Court on that occasion had declared that even if the crime were murder committed with a political motive it was a political crime. Mr. Lawrence also reminded the judge of the case of the late Mr. W. T. Stead, convicted of a crime, yet because of the unusual motive behind the crime, was allowed first division treatment and full freedom to receive his family and friends. Last of all the case of Dr. Jameson was cited. Although his raid resulted in the death of twenty-one persons and the

wounding of forty-six more, the political character of his offence was taken into account and he was made a first division prisoner.

They were men, fighting in a man's war. We of the W. S. P. U. were women, fighting in a woman's war. Lord Coleridge, therefore, saw in us only reckless and criminal defiers of law. Lord Coleridge said: "You have been convicted of a crime for which the law would sanction, if I chose to impose it, a sentence of two years' imprisonment with hard labour. There are circumstances connected with your case which the jury have very properly brought to my attention, and I have been asked by you all three to treat you as first class misdemeanants. If, in the course of this case, I had observed any contrition or disavowal of the acts you have committed, or any hope that you would avoid repetition of them in future, I should have been very much prevailed upon by the arguments that have been advanced to me."

No contrition having been expressed by us, the sentence of the Court was that we were to suffer imprisonment, in the second division, for the term of nine months, and that we were to pay the costs of the prosecution.

CHAPTER III

The sentence of nine months astonished us beyond measure, especially in view of certain very recent events, one of these being the case of some sailors who had mutinied in order to call attention to something which they considered a peril to themselves and to all seafarers. They were tried and found technically guilty, but because of the motive behind their mutiny, were discharged without punishment. Perhaps more nearly like our case than this was the case of the labour leader, Tom Mann, who, shortly before, had written a pamphlet calling upon His Majesty's soldiers not to fire upon strikers when commanded to do so by their superior officers. From the Government's point of view this was a much more serious kind of inciting than ours, because if it had been responded to the authorities would have been absolutely crippled in maintaining order. Besides, soldiers who refuse to obey orders are liable to the death penalty. Tom Mann was given a sentence of six months, but this was received, on the part of the Liberal Press and Liberal politicians, with so much clamour and protest that the prisoner was released at the end of two months. So, even on our way to prison, we told one another that our sentences could not stand. Public opinion would never permit the Government to keep us in prison for nine months, or in the second division for any part of our term. We agreed to wait seven Parliamentary days before we began a hunger strike protest.

It was very dreary waiting, those seven Parliamentary days, because we could not know what was happening outside, or what was being talked of in the House. We could know nothing of the protests and memorials that were pouring in, on our behalf, from Oxford and Cambridge Universities, from members of learned societies, and from distinguished men and women of all professions, not only in England but in every country of Europe, from the United States and Canada, and even from India. An international memorial asking that we be treated as political prisoners was signed by such great men and women as Prof. Paul Milyoukoff, leader of the Constitutional Democrats in the Duma; Signor Enrico Ferri, of the Italian Chamber of Deputies; Edward Bernstein, of the German Reichstag; George Brandes, Edward Westermarck, Madame Curie, Ellen Key, Maurice Maeterlinck, and many others. The greatest indignation was expressed in the House, Keir Hardie and Mr. George Lansbury leading in the demand for a drastic revision of our sentences and our immediate transference to the first division. So much pressure was brought to bear that within a few days the Home Secretary announced that he felt it his duty to examine into the circumstances of the case without delay. He explained that the prisoners had not at any time been forced to wear prison clothes. Ultimately, which in this case means shortly before the expiration of the seven Parliamentary days, we were all three placed in the first division. Mrs. Pethick Lawrence was given the cell formerly occupied by Dr. Jameson and I had the cell adjoining. Mr. Pethick Lawrence, in Brixton Gaol, was similarly accommodated. We all had the privilege of furnishing our cells with comfortable chairs, tables, our own bedding, towels, and so on. We had meals sent in from the outside; we wore our own clothing and had what books, newspapers and writing materials we required. We were not permitted to write or receive letters or to see our friends except in the ordinary two weeks' routine. Still we had gained our point that suffrage prisoners were politicals.

We had gained it, but, as it turned out, only for ourselves. When we made the inquiry, "Are all our women now transferred to the first division?" the answer was that the order for transference referred only to Mr. and Mrs. Pethick Lawrence and myself. Needless to say, we immediately refused to accept this unfair advantage, and after we had exhausted every means in our power to induce the Home Secretary to give the other suffrage prisoners the same justice that we had received, we adopted the protest of the hunger strike. The word flew swiftly through Holloway, and in some mysterious way travelled to Brixton, to Aylesbury, and Winson Green, and at once all the other suffrage prisoners followed our lead. The Government then had over eighty hunger strikers on their hands, and, as before, had ready only the argument of force, which means that disgusting and cruel process of forcible feeding.

Holloway became a place of horror and torment. Sickening scenes of violence took place almost every hour of the day, as the doctors went from cell to cell performing their hideous office. One of the men did his work in such brutal fashion that the very sight of him provoked cries of horror and anguish. I shall never while I live forget the suffering I experienced during the days when those cries were ringing in my ears. In her frenzy of pain one woman threw herself from the gallery on which her cell opened. A wire netting eight feet below broke her fall to the iron staircase beneath, else she must inevitably have been killed. As it was she was frightfully hurt.

The wholesale hunger strike created a tremendous stir throughout England, and every day in the House the Ministers were harassed with questions. The climax was reached on the third or fourth day of the strike, when a stormy scene took place in the House of Commons. The Under Home Secretary, Mr. Ellis Griffith, had been mercilessly questioned as to conditions under which the forcible feeding was being done, and as soon as this was over one of the suffragist members made a moving appeal to the Prime Minister himself to order the release of all the prisoners. Mr. Asquith, forced against his will to take part in the controversy, rose and said that it was not for him to interfere with the actions of his colleague, Mr. McKenna, and he added, in his own suave, mendacious manner: "I must point out this, that there is not one single prisoner who cannot go out of prison this afternoon on giving the undertaking asked for by the Home Secretary." Meaning an undertaking to refrain henceforth from militancy.

Instantly Mr. George Lansbury sprang to his feet and exclaimed: "You know they cannot! It is perfectly disgraceful that the Prime Minister of England should make such a statement."

Mr. Asquith glanced carelessly at the indignant Lansbury, but sank into his seat without deigning to reply. Shocked to the depths of his soul by the insult thrown at our women, Mr. Lansbury strode up to the Ministerial bench and confronted the Prime Minister, saying again: "That was a disgraceful thing for you to say, Sir. You are beneath contempt, you and your colleagues. You call yourselves gentlemen, and you forcibly feed and murder women in this fashion. You ought to be driven out of office. Talk about protesting. It is the most disgraceful thing that ever happened in the history of England. You will go down to history as the men who tortured innocent women."

By this time the House was seething, and the indignant Labour member had to shout at the top of his big voice in order to be heard over the din. Mr. Asquith's pompous order that Mr. Lansbury leave the House for the day was probably known to very few until it appeared in print next day. At all events Mr. Lansbury continued his protest for five minutes longer. "You murder, torture and drive women mad," he cried, "and then you tell them they can walk out. You ought to be ashamed of yourself. You talk about principle--you talk about fighting in Ulster--you, too--" turning to the Unionist benches--"You ought to be driven out of public life. These women are showing you what principle is. You ought to honour them for standing up for their womanhood. I tell you, Commons of England, you ought to be ashamed of yourselves."

The Speaker came to Mr. Asquith's rescue at last and adjured Mr. Lansbury that he must obey the Prime Minister's order to leave the House, saying that such disorderly conduct would cause the House to lose respect. "Sir," exclaimed Mr. Lansbury, in a final burst of righteous rage, "it has lost it already."

This unprecedented explosion of wrath and scorn against the Government was the sensation of the hour, and it was felt on all sides that the release of the prisoners, or at least cessation of forcible feeding, which amounted to the same thing, would be ordered. Every day the Suffragettes marched in great crowds to Holloway, serenading the prisoners and holding protest meetings to immense crowds. The music and the cheering, faintly wafted to our straining ears, was inexpressibly sweet. Yet it was while listening to one of these serenades that the most dreadful moment of my imprisonment occurred. I was lying in bed, very weak from starvation, when I heard a sudden scream from Mrs. Lawrence's cell, then the sound of a prolonged and very violent struggle, and I knew that they had dared to carry their brutal business to our doors. I sprang out of bed and, shaking with weakness and with anger, I set my back against the wall and waited for what might come. In a few moments they had finished with Mrs. Lawrence and had flung open the door of my cell. On the threshold I saw the doctors, and back of them a large group of wardresses. "Mrs. Pankhurst," began the doctor. Instantly I caught up a heavy earthenware water jug from a table hard by, and with hands that now felt no weakness I swung the jug head high.

"If any of you dares so much as to take one step inside this cell I shall defend myself," I cried. Nobody moved or spoke for a few seconds, and then the doctor confusedly muttered something about to-morrow morning doing as well, and they all retreated.

I demanded to be admitted to Mrs. Lawrence's cell, where I found my companion in a desperate state. She is a strong woman, and a very determined one, and it had required the united strength of nine wardresses to overcome her. They had rushed into the cell

without any warning, and had seized her unawares, else they might not have succeeded at all. As it was she resisted so violently that the doctors could not apply the stethoscope, and they had very great difficulty in getting the tube down. After the wretched affair was over Mrs. Lawrence fainted, and for hours afterwards was very ill.

This was the last attempt made to forcibly feed either Mrs. Lawrence or myself, and two days later we were ordered released on medical grounds. The other hunger strikers were released in batches, as every day a few more triumphant rebels approached the point where the Government stood in danger of committing actual murder. Mr. Lawrence, who was forcibly fed twice a day for more than ten days, was released in a state of complete collapse on July 1st. Within a few days after that the last of the prisoners were at liberty.

As soon as I was sufficiently recovered I went to Paris and had the joy of seeing again my daughter Christabel, who, during all the days of strife and misery, had kept her personal anxiety in the background and had kept staunchly at her work of leadership. The absence of Mr. and Mrs. Pethick Lawrence had thrown the entire responsibility of the editorship of our paper, _Votes for Women_, on her shoulders, but as she has invariably risen to meet new responsibility, she conducted the paper with skill and discretion.

We had much to talk about and to consider, because it was evident that militancy, instead of being dropped, as the other suffrage societies were constantly suggesting, must go on very much more vigorously than before. The struggle had been too long drawn out. We had to seek ways to shorten it, to bring it to such a climax that the Government would acknowledge that something had to be done. We had already demonstrated that our forces were impregnable. We could not be conquered, we could not be terrified, we could not even be kept in prison. Therefore, since the Government had their war lost in advance, our task was merely to hasten the surrender.

The situation in Parliament, as far as the suffrage question was concerned, was clean swept and barren. The third Conciliation Bill had failed to pass its second reading, the majority against it being fourteen.

Many Liberal members were afraid to vote for the bill because Mr. Lloyd-George and Mr. Lewis Harcourt had persistently spread the rumour that its passage, at that time, would result in splitting the Cabinet. The Irish Nationalist members had become hostile to the bill because their leader, Mr. Redmond, was an anti-suffragist, and had refused to include a woman suffrage clause in the Home Rule Bill. Our erstwhile friends, the Labour members, were so apathetic, or so fearful for certain of their own measures, that most of them stayed away from the House on the day the bill reached its second reading. So it was lost, and the Militants were blamed for its loss! In June the Government announced that Mr. Asquith's manhood suffrage bill would soon be introduced, and very soon after this the bill did appear. It simplified the registration machinery, reduced the qualifying period of residence to six months, and abolished property qualifications, plural voting and University representation. In a word, it gave the Parliamentary franchise to every man above the age of twenty-one and it denied it to all women. Never in the history of the suffrage movement had such an affront been offered to women, and never in the history of England had such a blow been aimed at women's liberties. It is true that the Prime Minister had pledged himself to introduce a bill capable of being amended to include women's suffrage, and to permit any amendment that passed its second reading to become a part of the bill. But we had no faith in an amendment, nor in any bill that was not from its inception an official Government measure. Mr. Asquith had broken every pledge he had ever made the women, and this new pledge impressed us not at all. Well we knew that he had given it only to cover his treachery in torpedoing the Conciliation Bill, and in the hope of placating the suffragists, perhaps securing another truce to militancy.

If this last was his hope he was most grievously disappointed. Signs were constantly appearing to indicate that women would no longer be contented with the symbolic militancy involved in window breaking. For example, traces were found in the Home Secretary's office at Whitehall of an attempt at arson. On the doorstep of another Cabinet Minister similar traces were found. Had the Government acted upon these warnings, by giving women the vote, all the serious acts of militancy that have occurred since would have been averted. But like the heart of Pharaoh, the heart of the Government hardened, and militant acts followed one another in rapid succession. In July the W. S. P. U. issued a manifesto which set forth our intentions in that regard. The manifesto read in part as follows:

"The leaders of the Women's Social and Political Union have so often warned the Government that unless the vote were granted to women in response to the mild militancy of the past, a fiercer spirit of revolt would be awakened which it would be impossible to control. The Government have blindly disregarded the warning, and now they are reaping the harvest of their unstatesmanlike folly."

This was issued immediately after a visit paid by Mr. Asquith to Dublin. The occasion had been intended to be one of great pomp and circumstance, a huge popular demonstration in honour of the sponsor of Home Rule, but the Suffragettes turned it into the most lamentable fiasco imaginable. From the hour of Mr. Asquith's attempted secret departure from London until his return he lived and moved in momentary dread of Suffragettes. Every time he entered or left a railway carriage or a steamer he was confronted by women. Every time he rose to speak he was interrupted by women. Every public appearance he made was turned into a riot by women. As he left Dublin a woman threw a hatchet into his motor car, without, however, doing him any injury. As a final protest against his reception by Irishmen, the Theatre Royal was set on fire by two women. The theatre was practically empty at the time, the performance having been completed, and the damage done was comparatively small, yet the two women chiefly concerned, Mrs. Leigh and Miss Evans, were given the barbarous sentences of five years each in prison. These were the first women sentenced to penal servitude in the history of our movement. Of course they did not serve their sentences. On entering Mountjoy Prison they put in the usual claim for first division treatment, and this being refused, they immediately adopted the hunger strike. A number of Irish Suffragettes were in Mountjoy at this time for a protest made against the exclusion of women from the Home Rule Bill. They were in the first division, and they were almost on the eve of their release, but such is the indomitable spirit of militancy that these women entered upon a sympathetic hunger strike. They were released, but the Government forbade the release of Mrs. Leigh and Miss Evans, that is, they ordered the authorities to retain the women as long as they could, by forcible feeding, be kept alive. After a struggle which, for fierceness and cruelty, is almost unparalleled in our annals, the two women fought their way out.

All during that summer militancy surged up and down throughout the Kingdom. A series of attacks on golf links was instituted, not at all in a spirit of wanton mischief, but with the direct and very practical object of reminding the dull and self-satisfied English public that when the liberties of English women were being stolen from them was no time to think of sports. The women selected country clubs where prominent Liberal politicians were wont to take their week-end pleasures, and with acids they burned great patches of turf, rendering the golf greens useless for the time being. They burned the words, Votes for Women, in some cases, and always they left behind them reminders that women were warring for their freedom. On one occasion when the Court was at Balmoral Castle in Scotland, the Suffragettes invaded the Royal golf links, and when Sunday morning dawned all the marking flags were found to have been replaced by W. S. P. U. flags hearing inscriptions such as "Votes for Women means peace for Ministers," "Forcible feeding must be stopped," and the like. The golf links were frequently visited by Suffragettes in order to question recreant ministers. Two women followed the Prime Minister to Inverness, where he was playing golf with Mr. McKenna. Approaching the men one Suffragette exclaimed: "Mr. Asquith, you must stop forcible feeding--" She got no farther, for Mr. Asquith, turning pale with rage--perhaps--retreated behind the Home Secretary, who, quite forgetting his manners, seized the Suffragette, crying out that he was going to throw her into the pond. "Then we will take you with us," the two retorted, after which a very lively scuffle ensued, and the women were not thrown into the pond.

[Illustration: A SUFFRAGETTE THROWING A BAG OF FLOUR AT MR. ASQUITH IN CHESTER]

This golf green activity really aroused more hostility against us than all the window-breaking. The papers published appeals to us not to interfere with a game that helped weary politicians to think clearly, but our reply to this was that it had not had any such effect on the Prime Minister or Mr. Lloyd-George. We had undertaken to spoil their sport and that of a large class of comfortable men in order that they should be obliged to think clearly about women, and women's firm determination to get justice.

I made my return to active work in the autumn by speaking at a great meeting of the W. S. P. U., held in the Albert Hall. At that meeting I had the announcement to make that the six years' association of Mr. and Mrs. Pethick Lawrence with the W. S. P. U. had ended.

Since personal dissensions have never been dwelt upon in the W. S. P. U., have never been allowed to halt the movement or to interfere for an hour with its progress, I shall not here say any more about this important dissension than I said at our first large meeting in Albert Hall after the holiday, on October 17th. That day a new paper was sold on the streets. It was called _The Suffragette_, it was edited by Christabel Pankhurst, and was henceforth to be the official organ of the Union. Both in this new paper and in _Votes for Women_, the following announcement appeared:

GRAVE STATEMENT BY THE LEADERS

At the first reunion of the leaders after the enforced holiday, Mrs. Pankhurst and Miss Christabel Pankhurst outlined a new militant policy which Mr. and Mrs. Pethick Lawrence found themselves altogether unable to approve.

Mrs. Pankhurst and Miss Christabel Pankhurst indicated that they were not prepared to modify their intentions, and recommended that Mr. and Mrs. Pethick Lawrence should resume control of the Paper, _Votes for Women_, and should leave the Women's Social and Political Union.

Rather than make schism in the ranks of the Union Mr. and Mrs. Pethick Lawrence consented to take this course.

This was signed by all four. That night at the meeting I further explained to the members that, hard as partings from old friends and comrades unquestionably were, we must remember that we were fighting in an army, and that unity of purpose and unity of policy are absolutely necessary, because without them the army is hopelessly weakened. "It is better," I said, "that those who cannot agree, cannot see eye to eye as to policy, should set themselves free, should part, and should be free to continue their policy as they see it in their own way, unfettered by those with whom they can no longer agree."

Continuing I said: "I give place to none in appreciation and gratitude to Mr. and Mrs. Pethick Lawrence for the incalculable services that they have rendered the militant movement for Woman Suffrage, and I firmly believe that the women's movement will be strengthened by their being free to work for woman suffrage in the future as they think best, while we of the Women's Social and Political Union shall continue the militant agitation for Woman Suffrage initiated by my daughter and myself and a handful of women more than six years ago."

I then went on to survey the situation in which the W. S. P. U. now stood and to outline the new militant policy which he had decided upon. This policy, to begin with, was relentless opposition, not only to the party in power, the Liberal Party, but to all parties in the coalition. I reminded the women that the Government that had tricked and betrayed us and was now plotting to make our progress towards citizenship doubly difficult, was kept in office through the coalition of three parties. There was the Liberal Party, nominally the governing party, but they could not live another day without the coalition of the Nationalist and the Labour parties. So we should say, not only to the Liberal Party but to the Nationalist Party and the Labour Party, "So long as you keep in office an anti-suffrage Government, you are parties to their guilt, and from henceforth we offer you the same opposition which we give to the people whom you are keeping in power with your support." I said further: "We have summoned the Labour Party to do their duty by their own programme, and to go into opposition to the Government on every question until the Government do justice to women. They apparently are not willing to do that. Some of them tell us that other things are more important than the liberty of women--than the liberty of working women. We say, 'Then, gentlemen, we must teach you the value of your own principles, and until you are prepared to stand for the right of women to decide their lives and the laws under which they shall live, you, with Mr. Asquith and company, are equally responsible for all that has happened and is happening to women in this struggle for emancipation.'"

Outlining further our new and stronger policy of aggression, I said: "There is a great deal of criticism, ladies and gentlemen, of this movement. It always seems to me when the anti-suffrage members of the Government criticise militancy in women that it is very like beasts of prey reproaching the gentler animals who turn in desperate resistance when at the point of death. Criticism from gentlemen who do not hesitate to order out armies to kill and slay their opponents, who do not hesitate to encourage party mobs to attack defenceless women in public meetings--criticism from them hardly rings true. Then I get letters from people who tell me that they are ardent suffragists but who say that they do not like the recent developments in the militant movement, and implore me to urge the members not to be reckless with human life. Ladies and gentlemen, the only recklessness the militant suffragists have shown about human life has been about their own lives and not about the lives of others, and I say here and now that it has never been and never will be the policy of the Women's Social and Political Union recklessly to endanger human life. We leave that to the enemy. We leave that to the men in their warfare. It is not the method of women. No, even from the point of view of public policy, militancy affecting the security of human life would be out of place. _There is something that governments care far more for than human life, and that is the security of property, and so it is through property that we shall strike the enemy._ From henceforward the women who agree with me will say, 'We disregard your laws, gentlemen, we set the liberty and the dignity and the welfare of women above all such considerations, and we shall continue this war, as we have done in the past; and what sacrifice of property, or what injury to property accrues will not be our fault. It will be the fault of that Government who admit the justice of our demands, but refuses to concede them without the evidence, so they have told us, afforded to governments of the past, that those who asked for liberty were in earnest in their demands!"

I called upon the women of the meeting to join me in this new militancy, and I reminded them anew that the women who were fighting in the Suffragette army had a great mission, the greatest mission the world has ever known--the freeing of one-half the human race, and through that freedom the saving of the other half. I said to them: "Be militant each in your own way. Those of you who can express your militancy by going to the House of Commons and refusing to leave without satisfaction, as we did in the early

days--do so. Those of you who can express militancy by facing party mobs at Cabinet Ministers' meetings, when you remind them of their falseness to principle--do so. Those of you who can express your militancy by joining us in our anti-Government by-election policy--do so. Those of you who can break windows--break them. Those of you who can still further attack the secret idol of property, so as to make the Government realise that property is as greatly endangered by women's suffrage as it was by the Chartists of old--do so. And my last word is to the Government: I incite this meeting to rebellion. I say to the Government: You have not dared to take the leaders of Ulster for their incitement to rebellion. Take me if you dare, but if you dare I tell you this, that so long as those who incited to armed rebellion and the destruction of human life in Ulster are at liberty, you will not keep me in prison. So long as men rebels--and voters--are at liberty, we will not remain in prison, first division or no first division."

I ask my readers, some of whom no doubt will be shocked and displeased at these words of mine that I have so frankly set down, to put themselves in the place of those women who for years had given their lives entirely and unstintingly to the work of securing political freedom for women; who had converted so great a proportion of the electorate that, had the House of Commons been a free body, we should have won that freedom years before; who had seen their freedom withheld from them through treachery and misuse of power. I ask you to consider that we had used, in our agitation, only peaceful means until we saw clearly that peaceful means were absolutely of no avail, and then for years we had used only the mildest militancy, until we were taunted by Cabinet Ministers, and told that we should never get the vote until we employed the same violence that men had used in their agitation for suffrage. After that we had used stronger militancy, but even that, by comparison with the militancy of men in labour disputes, could not possibly be counted as violent. Through all these stages of our agitation we had been punished with the greatest severity, sent to prison like common criminals, and of late years tortured as no criminals have been tortured for a century in civilised countries of the world. And during all these years we had seen disastrous strikes that had caused suffering and death, to say nothing at all of the enormous economic waste, and we had never seen a single strike leader punished as we had been. We, who had suffered sentences of nine months' imprisonment for inciting women to mild rebellion, had seen a labour leader who had done his best to incite an army to mutiny released from prison in two months by the Government. And now we had come to a point where we saw civil war threatened, where we read in the papers every day reports of speeches a thousand times more incendiary than anything we had ever said. We heard prominent members of Parliament openly declaring that if the Home Rule Bill was passed Ulster would fight, and Ulster would be right. None of these men were arrested. Instead they were applauded. Lord Selborne, one of our sternest critics, referring to the fact that Ulstermen were drilling under arms, said publicly: "The method which the people of Ulster are adopting to show the depths of their convictions and the intensity of their feelings will impress the imagination of the whole country." But Lord Selborne was not arrested. Neither were the mutinous officers who resigned their commissions when ordered to report for duty against the men of Ulster who were actually preparing for civil war.

What does all this mean? Why is it that men's blood-shedding militancy is applauded and women's symbolic militancy punished with a prison cell and the forcible feeding horror? It means simply this, that men's double standard of sex morals, whereby the victims of their lust are counted as outcasts, while the men themselves escape all social censure, really applies to morals in all departments of life. Men make the moral code and they expect women to accept it. They have decided that it is entirely right and proper for men to fight for their liberties and their rights, but that it is not right and proper for women to fight for theirs.[3]

They have decided that for men to remain silently quiescent while tyrannical rulers impose bonds of slavery upon them is cowardly and dishonourable, but that for women to do that same thing is not cowardly and dishonourable, but merely respectable. Well, the Suffragettes absolutely repudiate that double standard of morals. If it is right for men to fight for their freedom, and God knows what the human race would be like to-day if men had not, since time began, fought for their freedom, then it is right for women to fight for their freedom and the freedom of the children they bear. On this declaration of faith the militant women of England rest their case.

FOOTNOTE:

[3] There is no question that a great deal of the animus directed against us during 1913 and 1914 by the Government was due to sex bitterness stirred up by a series of articles written by Christabel Pankhurst and published in _The Suffragette_. These articles, a fearless and authoritative expose of the evils of sexual immoralities and their blasting effect on innocent wives and children, have since been published in a book called "The Great Scourge, and how to end it," issued by David Nutt, New Oxford Street, London W. C.

CHAPTER IV

I had called upon women to join me in striking at the Government through the only thing that governments are really very much concerned about--property--and the response was immediate. Within a few days the newspapers rang with the story of the attack made on letter boxes in London, Liverpool, Birmingham, Bristol, and half a dozen other cities. In some cases the boxes, when opened by postmen, mysteriously burst into flame; in others the letters were destroyed by corrosive chemicals; in still others the addresses were rendered illegible by black fluids. Altogether it was estimated that over 5,000 letters were completely destroyed and many thousands more were delayed in transit.

It was with a deep sense of their gravity that these letter-burning protests were undertaken, but we felt that something drastic must be done in order to destroy the apathy of the men of England who view with indifference the suffering of women oppressed by unjust laws. As we pointed out, letters, precious though they may be, are less precious than human bodies and souls. This fact was universally realised at the sinking of the _Titanic_. Letters and valuables disappeared forever, but their loss was forgotten in the far more terrible loss of the multitude of human lives. And so, in order to call attention to greater crimes against human beings, our letter burnings continued.

In only a few cases were the offenders apprehended, and one of the few women arrested was a helpless cripple, a woman who could move about only in a wheeled chair. She received a sentence of eight months in the first division, and, resolutely hunger striking, was forcibly fed with unusual brutality, the prison doctor deliberately breaking one of her teeth in order to insert a gag. In spite of her disabilities and her weakness the crippled girl persisted in her hunger strike and her resistance to prison rules, and within a short time had to be released. The excessive sentences of the other pillar box destroyers resolved themselves into very short terms because of the resistance of the prisoners, every one of whom adopted the hunger strike.

Having shown the Government that we were in deadly earnest when we declared that we would adopt guerrilla warfare, and also that we would not remain in prison, we announced a truce in order that the Government might have full opportunity to fulfil their pledge in regard to a woman suffrage amendment to the Franchise Bill. We did not, for one moment, believe that Mr. Asquith would willingly keep his word. We knew that he would break it if he could, but there was a bare chance that he would not find this possible. However, our principal reason for declaring the truce was that we believed that the Prime Minister would find a way of evading his promise, and we were determined that the blame should be placed, not on militancy, but on the shoulders of the real traitor. We reviewed the history of past suffrage bills: In 1908 the bill had passed its second reading by a majority of 179; and then Mr. Asquith had refused to allow it to go on; in 1910 the Conciliation Bill passed its second reading by a majority of 110, and again Mr. Asquith blocked its progress, pledging himself that if the bill were reintroduced in 1911, in a form rendering it capable of free amendment, it would be given full facilities for becoming law; these conditions were met in 1911, and we saw how the bill, after receiving the increased majority of 167 votes, was torpedoed by the introduction of a Government manhood suffrage bill. Mr. Asquith this time had pledged himself that the bill would be so framed that a woman suffrage amendment could be added, and he further pledged that in case such an amendment was carried through its second reading, he would allow it to become a part of the bill. Just exactly how the Government would manage to wriggle out of their promise was a matter of excited speculation.

All sorts of rumours were flying about, some hinting at the resignation of the Prime Minister, some suggesting the possibility of a general election, others that the amended bill would carry with it a forced referendum on women's suffrage. It was also said that the intention of the Government was to delay the bill so long that, after it was passed in the House, it would be excluded from the benefits of the Parliament Acts, according to which a bill, delayed of passage beyond the first two years of the life of a Parliament, has no chance of being considered by the Lords. In order to become a law without the sanction of the House of Lords, a bill must pass three times through the House of Commons. The prospect of a woman suffrage bill doing that was practically nil.

To none of the rumours would Mr. Asquith give specific denial, and in fact the only positive utterance he made on the subject of the Franchise Bill was that he considered it highly improbable that the House would pass a woman suffrage amendment. In order to discourage woman suffrage sentiment in the House, Mr. Lloyd-George and Mr. Lewis Harcourt again busied themselves with spreading pessimistic prophecies of a Cabinet split in case an amendment was carried. No other threat, they well knew, would so terrorize the timid back bench Liberals, who, in addition to their blind party loyalty, stood in fear of losing their seats in the general election which would follow such a split. Rather than risk their political jobs they would have sacrificed any principle. Of course the hint of a Cabinet split was pure buncombe, and it deceived few of the members. But it established very clearly one thing, and this was that Mr. Asquith's promise that the House should be left absolutely free to decide the suffrage issue, and that the Cabinet stood ready to bow to the decision of the House was never meant to be fulfilled.

The Franchise Bill unamended, by its very wording, specifically denied the right of any woman to vote. Sir Edward Grey moved an amendment deleting from the bill the word male, thus leaving room for a women's suffrage amendment. Two such amendments were moved, one providing for adult suffrage for men and women, and the other providing full suffrage for women householders and wives of householders. The latter postponed the voting age of women to twenty-five years, instead of the men's twenty-one. On January 24th, 1913, debate on the first of the amendments was begun. A day and a half had been allotted to consideration of Sir Edward Grey's amendment, which if carried would leave the way clear for consideration of the other two, to each of which one-third of a day was allotted.

We had arranged for huge meetings to be held every day during the debates, and on the day before they were to open we sent a deputation of working women, led by Mrs. Drummond and Miss Annie Kenney, to interview Mr. Lloyd-George and Sir Edward Grey. We had asked Mr. Asquith to receive the deputation, but, as usual, he refused. The deputation consisted of the two leaders, four cotton mill operatives from Lancashire, four workers in sweated trades of London, two pit brow lassies, two teachers, two trained nurses, one shop assistant, one laundress, one boot and shoe worker and one domestic worker, twenty in all, the exact number specified by Mr. Lloyd-George. Some hundreds of working women escorted the deputation to the official residence of the Chancellor of the Exchequer and waited anxiously in the street to hear the result of the audience.

The result was, of course, barren. Mr. Lloyd-George glibly repeated his confidence in the "great opportunity" afforded by the Franchise Bill, and Sir Edward Grey, reminding the women of the divergence of view held by the members of Cabinet on the suffrage question, assured them that their best opportunity for success lay in an amendment to the present bill. The women spoke with the greatest candour to the two ministers and questioned them sharply as to the integrity of the Prime Minister's pledge to accept the amendments, if passed. To such depth of infamy had English politics sunk that it was possible for women openly to question the plighted word of the King's chief Minister! Mrs. Drummond, who stands in awe of no human being, in plain words invited the slippery Mr. Lloyd-George to clear his own character from obloquy. In the closing words of her speech she put the whole matter clearly up to him, saying: "Now, Mr. Lloyd-George, you have doggedly stuck to your old age pensions, and the insurance act, and secured them, and what you have done for these measures you can do also for the women."

The House met on the following afternoon to debate Sir Edward Grey's permissive amendment, but no sooner had the discussion opened than a veritable bombshell was cast into the situation. Mr. Bonar Law arose and asked for a ruling on the constitutionality of a woman's suffrage amendment to the bill as framed. The Speaker, who, besides acting as the presiding officer of the House, is its official parliamentarian, replied that, in his opinion, such an amendment would make a huge difference in the bill, and that he would be obliged, at a later stage of the debates, to consider carefully whether, if carried, any woman suffrage amendment would not so materially alter the bill that it would have to be withdrawn. In spite of this sinister pronouncement, the House continued to debate the Grey amendment, which was ably supported by Lord Hugh Cecil, Sir John Rolleston, and others.

During the intervening week-end holiday two Cabinet councils were held, and when the House met on Monday the Prime Minister called upon the Speaker for his ruling. The Speaker declared that, in his opinion, the passage of any one of the woman suffrage amendments would so alter the scope of the Franchise Bill as practically to create a new bill, because the measure, as it was framed, did not have for its main object the bestowal of the franchise on a hitherto excluded class. Had it been so framed a woman suffrage amendment would have been entirely proper. But the main object of the bill was to alter the qualification, or the basis of registration for a Parliamentary vote. It would increase the male electorate, but only as an indirect result of the changed qualifications. An amendment to the bill removing the sex barrier from the election laws was not, in the Speaker's opinion, a proper one.

The Prime Minister then announced the intentions of the Cabinet, which were to withdraw the Franchise Bill and to refrain from introducing, during that session, a plural voting bill. Mr. Asquith blandly admitted that his pledge in regard to women's suffrage had been rendered incapable of fulfilment, and he said that he felt constrained to give a new pledge to take its place. There were only two that could be given. The first was that the Government should bring in a bill to enfranchise women, and this the Government would not do. The second was that the Government agree to give full facilities as to time, during the next session of Parliament, to a private member's bill, so drafted as to be capable of free amendment. This was the course that the Government had decided to adopt. Mr. Asquith had the effrontery to say in conclusion that he thought that the House would agree that he had striven and had succeeded in giving effect, both in letter and in spirit, to every undertaking which the Government had given.

Two members only, Mr. Henderson and Mr. Keir Hardie had the courage to stand up on the floor of the House and denounce the Government's treachery, for treachery it unquestionably was. Mr. Asquith had pledged his sacred honour to introduce a bill that

would be capable of an amendment to include women's suffrage, and he had framed a bill that could not be so amended. Whether he had done the thing deliberately, with the plain intention of selling out the women, or whether ignorance of Parliamentary rules accounted for the failure of the bill was immaterial. The bill need not have been drawn in ignorance. The fount of wisdom represented by Mr. Speaker could have been consulted at the time the bill was under construction quite as easily as when it had reached the debating stage. Our paper said editorially, representing and perfectly expressing our member's views: "Either the Government are so ignorant of Parliamentary procedure that they are unfit to occupy any position of responsibility, or else they are scoundrels of the worst kind."

I am inclined to think that the verdict of posterity will lean towards the later conclusion. If Mr. Asquith had been a man of honour he would have reframed the Franchise Bill in such a way that it could have included a suffrage amendment, or else he would have made amends for his stupendous blunder--if it was a blunder--by introducing a Government measure for women's suffrage. He did neither, but disposed of the matter by promising facilities for a private member's bill which he knew, and which everybody knew, could not possibly pass.

There was no chance for a private member's bill, even with facilities, because of a number of reasons, but principally because the torpedoing of the Conciliation Bill had destroyed utterly the spirit of conciliation in which Conservatives, Liberals and Radicals in the House of Commons, and militant and non-militant women throughout the Kingdom had set aside their differences of opinion and agreed to come together on a compromise measure. When the second Conciliation Bill, of 1911, was under discussion, Lord Lytton had said: "If this bill does not go through, the woman suffrage movement will not be stopped, but the spirit of conciliation of which this bill is an expression will be destroyed, and there will he war throughout the country, raging, tearing, fierce, bitter strife, though nobody wants it."

Lord Lytton's words were prophetic. At this last brazen piece of trickery on the part of the Government the country blazed with bitter wrath. All the suffrage societies united in calling for a Government measure for women's suffrage to be introduced without delay. The idle promise of facilities for a private member's bill was rejected with contumely and scorn. The Liberal women's executive committee met, and a strong effort was made to pass a resolution threatening the withdrawal from party work of the entire federation, but this failed and the executive merely passed a feeble resolution of regret.

The membership of the Women's Liberal Federation was, at that time, close to 200,000, and if the executive had passed the strong resolution, refusing to do any more work for the party until a Government measure had been introduced, the Government would have been forced to yield. They could not have faced the country without the support of the women. But these women, many of them, were wives of men in the service, the paid service of the Liberal Party. Many of them were wives of Liberal members. They lacked the courage, or the intelligence, or the insight, to declare war as a body on the Government. A large number of women, and also many men, did resign from the Liberal Party, but the defections were not serious enough to affect the Government.

The militants declared, and proceeded instantly to carry out, unrelenting warfare. We announced that either we must have a Government measure, or a Cabinet split--those men in the Cabinet calling themselves suffragists going out--or we would take up the sword again, never to lay it down until the enfranchisement of the women of England was won.

It was at this time, February, 1913, less than two years ago as I write these words, that militancy, as it is now generally understood by the public began--militancy in the sense of continued, destructive, guerilla warfare against the Government through injury to private property. Some property had been destroyed before this time, but the attacks were sporadic, and were meant to be in the nature of a warning as to what might become a settled policy. Now we indeed lighted the torch, and we did it with the absolute conviction that no other course was open to us. We had tried every other measure, as I am sure that I have demonstrated to my readers, and our years of work and suffering and sacrifice had taught us that the Government would not yield to right and justice, what the majority of members of the House of Commons admitted was right and justice, but that the Government would, as other governments invariably do, yield to expediency. Now our task was to show the Government that it was expedient to yield to the women's just demands. In order to do that we had to make England and every department of English life insecure and unsafe. We had to make English law a failure and the courts farce comedy theatres; we had to discredit the Government and Parliament in the eyes of the world; we had to spoil English sports, hurt business, destroy valuable property, demoralise the world of society, shame the churches, upset the whole orderly conduct of life--

That is, we had to do as much of this guerilla warfare as the people of England would tolerate. When they came to the point of saying to the Government: "Stop this, in the only way it can be stopped, by giving the women of England representation," then we

should extinguish our torch.

Americans, of all people, ought to see the logic of our reasoning. There is one piece of American oratory, beloved of schoolboys, which has often been quoted from militant platforms. In a speech now included among the classics of the English language your great statesman, Patrick Henry, summed up the causes that led to the American Revolution. He said: "We have petitioned, we have remonstrated, we have supplicated, we have prostrated ourselves at the foot of the throne, and it has all been in vain. We must fight--I repeat it, sir, we must fight."

Patrick Henry, remember, was advocating killing people, as well as destroying private property, as the proper means of securing the political freedom of men. The Suffragettes have not done that, and they never will. In fact the moving spirit of militancy is deep and abiding reverence for human life. In the latter course of our agitation I have been called upon to discuss our policies with many eminent men, politicians, literary men, barristers, scientists, clergymen. One of the last named, a high dignitary of the Church of England, told me that while he was a convinced suffragist, he found it impossible to justify our doing wrong that right might follow. I said to him: "We are not doing wrong--we are doing right in our use of revolutionary methods against private property. It is our work to restore thereby true values, to emphasise the value of human rights against property rights. You are well aware, sir, that property has assumed a value in the eyes of men, and in the eyes of the law, that it ought never to claim. It is placed above all human values. The lives and health and happiness, and even the virtue of women and children--that is to say, the race itself--are being ruthlessly sacrificed to the god of property every day of the world."

To this my reverend friend agreed, and I said: "If we women are wrong in destroying private property in order that human values may be restored, then I say, in all reverence, that it was wrong for the Founder of Christianity to destroy private property, as He did when He lashed the money changers out of the Temple and when He drove the Gaderene swine into the sea."

It was absolutely in this spirit that our women went forth to war. In the first month of guerilla warfare an enormous amount of property was damaged and destroyed. On January 31st a number of putting greens were burned with acids; on February 7th and 8th telegraph and telephone wires were cut in several places and for some hours all communication between London and Glasgow were suspended; a few days later windows in various of London's smartest clubs were broken, and the orchid houses at Kew were wrecked and many valuable blooms destroyed by cold. The jewel room at the Tower of London was invaded and a showcase broken. The residence of H. R. H. Prince Christian and Lambeth Palace, seat of the Archbishop of Canterbury, were visited and had windows broken. The refreshment house in Regents Park was burned to the ground on February 12th and on February 18th a country house which was being built at Walton-on-the-Hill for Mr. Lloyd-George was partially destroyed, a bomb having been exploded in the early morning before the arrival of the workmen. A hat pin and a hair pin picked up near the house--coupled with the fact that care had been taken not to endanger any lives--led the police to believe that the deed had been done by women enemies of Mr. Lloyd-George. Four days later I was arrested and brought up in Epsom police court, where I was charged with having "counselled and procured" the persons who did the damage. Admitted to bail for the night, I appeared next morning in court, where the case was fully reviewed. Speeches of mine were read, one speech, made at a meeting held on January 22nd, in which I called for volunteers to act with me in a particular engagement; and another, made the day after the explosion, in which I publicly accepted responsibility for all militant acts done in the past, and even for what had been done at Walton. At the conclusion of the hearing I was committed for trial at the May Assizes at Guildford. Bail would be allowed, it was stated, if I would agree to give the usual undertaking to refrain from all militancy or incitement to militancy.

I asked that the case be set for speedy trial at the Assizes then in progress. I was entirely willing, I said, to give an undertaking for a short period, for a week, or even two weeks, but I could not possibly do so for a much longer period, looking at the fact that a new session of Parliament began in March, and was vitally concerned with the interests of women. The request was refused, and I was ordered to be taken to Holloway. I warned the magistrate that I should at once adopt the hunger strike, and I told him that if I lived at all until the summer it would be a dying woman who would come up for trial.

Arriving at Holloway I carried out my intention, but within twenty-four hours I heard that the authorities had arranged that my trial should take place on April 1st, instead of at the end of June, and at the Central Criminal Court, London, instead of the Guildford Court. I then gave the required under-takings and was immediately released on bail.

CHAPTER V

When I entered Old Bailey on that memorable Wednesday, April 2nd, 1913, to be tried for inciting to commit a felony, the court was packed with women. A great crowd of women who could not obtain the necessary tickets remained in the streets below for hours waiting news of the trial. A large number of detectives from Scotland Yard, and a still larger number of uniformed police were on duty both inside and outside the court. I could not imagine why it was considered necessary to have such a regiment of police on hand, for I had not, at that time, realised the state of terror into which the militant movement, in its new development, had thrown the authorities.

Mr. Bodkin and Mr. Travers Humphreys appeared to prosecute on behalf of the Crown, and I conducted my own case, in consultation with my solicitor, Mr. Marshall. The Judge, Mr. Justice Lush, having taken his seat I entered the dock and listened to the reading of the indictment. I pled "not guilty," not because I wished to evade responsibility for the explosion,--I had already assumed that responsibility--but because the indictment accused me of having wickedly and maliciously incited women to crime. What I had done was not wicked of purpose, but quite the opposite of wicked. I could not therefore truthfully plead guilty. The trial having opened the Judge courteously asked me if I would like to sit down. I thanked him, and asked if I might also have a small table on which to place my papers. By orders of the Judge a table was brought me.

Mr. Bodkin opened the case by explaining the "Malicious Damages to Property Act" of 1861, under which I was charged, and after describing the explosion which had damaged the Lloyd-George house at Walton, said that I was accused of being in the affair an accessory before the fact. It was not suggested, he said, that I was present when the crime was committed, but it was charged that I had moved and incited, counselled and procured women whose names were unknown to carry out that crime. It would be for the jury to decide, after the evidence had been presented, whether the facts did not point most clearly to the conclusion that women, probably two in number, who committed the crime were members of the Women's Social and Political Union, which had its office in Kingsway in London, and of which the defendant was the head, moving spirit and recognised leader.

The blowing up of Mr. Lloyd-George's house was then described in detail. That the damage was intended as an act against Mr. Lloyd-George was clear, Mr. Bodkin said, from the malicious statements made against him by the prisoner. He produced a private letter written by me to a friend in which I had defended militancy, and said that not only had it become a duty but in the circumstances it had also become a political necessity. Said Mr. Bodkin:

"A letter of that kind proves very clearly several things. It shows that she is the leader. It shows her influence over the emotional members of this organisation. It shows that according to her, militancy can be withheld for a time and let loose upon society at another time. And it further shows that any person or any woman who wants to indulge in militancy, which is only a picturesque expression for committing crimes against society, has to communicate with her, and with her alone, by word of mouth or by letter. That is the Proclamation which went out to the members of this organisation. The plain language of that letter is, 'If we don't get what we want, the Government and their members will be responsible, and the Government and the public will be bullied into giving us what we want.'"

Many extracts from my speeches made in January and February were read, and the final speech made just before my arrest at Chelsea. But before they were read I said:

"I wish to lodge an objection now to the police reports of my speeches. They have been supplied to me, and the only report I accept is that of the journalist of Cardiff who is one of the witnesses. He has furnished a fairly accurate report of what I said in that town. The police reports I do not accept. They are grossly inaccurate and ignorant and ungrammatical, and they convey an absolutely wrong impression of what I said in many respects."

Witnesses were then examined; the carter who heard and reported the explosion; the foreman in charge of the damaged house, who told the cost of the damages, and described the explosives, etc., found on the premises; several police officers who told of finding hairpins and a woman's rubber golosh in the house, and so on. Absolutely nothing was brought out that tended to show that the Suffragettes had anything to do with the affair. The Judge noted this for he said to Mr. Bodkin:

"I am not quite sure how you present this case. There are two ways of looking at it. Do you only ask the jury to say that the defendant specifically counselled the perpetration of this crime, or do you also say that, looking at her speeches that you read--assuming you prove that they were uttered--that the language used being a general incitement to damage property, any one who acted on this invitation and perpetrated this outrage would be incited by her to do it?"

Mr. Bodkin replied that the latter assumption was correct.

"I say that the speeches generally are incitement to all kinds of acts of violence against property, and that they present evidence of attacks against property and a particular individual, and that there is evidence in the speeches which have been read, and which will be proved, of admissions by Mrs. Pankhurst of having been connected with the particular outrage in a way which makes her in law an accessory before the fact."

"But you do not confine the case to the latter way of putting it?"

"No," replied Mr. Bodkin.

"Even if the jury are satisfied," said the Judge, "that Mrs. Pankhurst was not directly connected with this outrage by counselling it, you still ask the jury to say that by counselling, as you say she had in the speeches, the destruction of property, especially that belonging to a particular gentleman, anybody who acted on that and committed this outrage would have been incited by her to do it?"

"Yes, my lord."

"I think, Mrs. Pankhurst, you now understand the way it is put?" asked the Judge.

"I understand it quite well, my lord," I replied.

Proceedings were resumed on the following day, and the examination of witnesses for the prosecution went on. At the close of the examination, the Judge inquired whether I desired to call any witnesses. I replied:

"I do not desire to give evidence or to call any witnesses, but I desire to address your Lordship."

I began by objecting to some of the things Mr. Bodkin had said in his speech which concerned me personally. He had referred to me--or at least his words conveyed the suggestion--that I was a woman riding about in my motor car inciting other women to do acts which entail imprisonment and great suffering, while I, perhaps indulging in some curious form of pleasure, was protected, or thought myself protected, from serious consequences. I said that Mr. Bodkin knew perfectly well that I shared all the dangers the other women faced, that I had been in prison three times, serving two of the sentences in full, and being treated like an ordinary felon--searched, put in prison clothes, eating prison fare, given solitary confinement and conforming to all the abominable rules imposed upon women who commit crimes in England. I thought I owed it to myself, especially as the same suggestions--in regard to the luxury in which I lived, supported by the members of the W. S. P. U.--had been made, not only by Mr. Bodkin in court, but by members of the Government in the House of Commons--I thought I owed it to myself to say that I owned no motor car and never had owned one. The car in which I occasionally rode was owned by the organisation and was used for general propaganda work. In that car, and in cars owned by friends I had gone about my work as a speaker in the Woman Suffrage movement. It was equally untrue, I said, that some of us were making incomes of L1,000 to L1,500 a year out of the suffrage movement, as had actually been alleged in the debates in the House in which members of Parliament were trying to decide how to crush militancy. No woman in our organisation was making any such income, or anything remotely like it. Myself, I had sacrificed a considerable portion of my income because I had to surrender a very important part of it in order to be free to do what I thought was my duty in the movement.

Addressing myself to my defence I told the Court that it was a very serious condition of things when a large number of respectable and naturally law abiding people, people of upright lives, came to hold the law in contempt, came seriously to making up their minds that they were justified in breaking the law.

"The whole of good government," I said, "rests upon acceptance of the law, upon respect of the law, and I say to you seriously, my lord, and gentlemen of the jury, that women of intelligence, women of training, women of upright life, have for many years ceased to respect the laws of this country. It is an absolute fact, and when you look at the laws of this country as they effect women it is not to be wondered at."

At some length I went over these laws, laws that made it possible for the Judge to send me, if found guilty, to prison for fourteen years, while the maximum penalty for offences of the most revolting kind against little girls was only two years' imprisonment. The laws of inheritance, the laws of divorce, the laws of guardianship of children--all so scandalously unjust to women, I sketched briefly, and I said that not only these laws and others, but the administration of the laws fell so far short of adequacy that women felt that they must be permitted to share the work of cleaning up the entire situation. I tried here to tell of certain dreadful things that I had learned as the wife of a barrister, things about some of the men in high places who are entrusted with the administration of the law, of a judge of Assizes where many hideous crimes against women were tried, this judge himself being found dead one morning

in a brothel, but the Court would not allow me to go into personalities, as he called it, with regard to "distinguished people," and told me that the sole question before the jury was whether or not I was guilty as charged. I must speak on that subject and on no other.

After a hard fight to be allowed to tell the jury the reasons why women had lost respect for the law, and were making such a struggle in order to become law makers themselves, I closed my speech by saying:

"Over one thousand women have gone to prison in the course of this agitation, have suffered their imprisonment, have come out of prison injured in health, weakened in body, but not in spirit. I come to stand my trial from the bedside of one of my daughters, who has come out of Holloway Prison, sent there for two months' hard labour for participating with four other people in breaking a small pane of glass. She has hunger-struck in prison. She submitted herself for more than five weeks to the horrible ordeal of feeding by force, and she has come out of prison having lost nearly two stone in weight. She is so weak that she cannot get out of her bed. And I say to you, gentlemen, that is the kind of punishment you are inflicting upon me or any other woman who may be brought before you. I ask you if you are prepared to send an incalculable number of women to prison--I speak to you as representing others in the same position--if you are prepared to go on doing that kind of thing indefinitely, because that is what is going to happen. There is absolutely no doubt about it. I think you have seen enough even in this present case to convince you that we are not women who are notoriety hunters. We could get that, heaven knows, much more cheaply if we sought it. We are women, rightly or wrongly, convinced that this is the only way in which we can win power to alter what for us are intolerable conditions, absolutely intolerable conditions. A London clergyman only the other day said that 60 per cent. of the married women in his parish were breadwinners, supporting their husbands as well as their children. When you think of the wages women earn, when you think of what this means to the future of the children of this country, I ask you to take this question very, very seriously. Only this morning I have had information brought to me which could be supported by sworn affidavits, that there is in this country, in this very city of London of ours, a regulated traffic, not only in women of full age, but in little children; that they are being purchased, that they are being entrapped, and that they are being trained to minister to the vicious pleasures of persons who ought to know better in their positions of life.

"Well, these are the things that have made us women determined to go on, determined to face everything, determined to see this thing out to the end, let it cost us what it may. And if you convict me, gentlemen, if you find me guilty, I tell you quite honestly and quite frankly, that whether the sentence is a long sentence, whether the sentence is a short sentence, I shall not submit to it. I shall, the moment I leave this court, if I am sent to prison, whether to penal servitude or to the lighter form of imprisonment--because I am not sufficiently versed in the law to know what his lordship may decide; but whatever my sentence is, from the moment I leave this court I shall quite deliberately refuse to eat food--I shall join the women who are already in Holloway on the hunger strike. I shall come out of prison, dead or alive, at the earliest possible moment; and once out again, as soon as I am physically fit I shall enter into this fight again. Life is very dear to all of us. I am not seeking, as was said by the Home Secretary, to commit suicide. I do not want to commit suicide. I want to see the women of this country enfranchised, and I want to live until that is done. Those are the feelings by which we are animated. We offer ourselves as sacrifices, just as your forefathers did in the past, in this cause, and I would ask you all to put this question to yourselves:--Have you the right, as human beings, to condemn another human being to death--because that is what it amounts to? Can you throw the first stone? Have you the right to judge women?

"You have not the right in human justice, not the right by the constitution of this country, if rightly interpreted, to judge me, because you are not my peers. You know, every one of you, that I should not be standing here, that I should not break one single law--if I had the rights that you possess, if I had a share in electing those who make the laws I have to obey; if I had a voice in controlling the taxes I am called upon to pay, I should not be standing here. And I say to you it is a very serious state of things. I say to you, my lord, it is a very serious situation, that women of upright life, women who have devoted the best of their years to the public weal, that women who are engaged in trying to undo some of the terrible mistakes that men in their government of the country have made, because after all, in the last resort, men are responsible for the present state of affairs--I put it to you that it is a very serious situation. You are not accustomed to deal with people like me in the ordinary discharge of your duties; but you are called upon to deal with people who break the law from selfish motives. I break the law from no selfish motive. I have no personal end to serve, neither have any of the other women who have gone through this court during the past few weeks, like sheep to the slaughter. Not one of these women would, if women were free, be law-breakers. They are women who seriously believe that this hard path that they are treading is the only path to their enfranchisement. They seriously believe that the welfare of humanity demands this sacrifice; they believe that the horrible evils which are ravaging our civilisation will never be removed until women get the vote. They know that the very fount of life is being poisoned; they know that homes are being destroyed; that because of bad education, because of the unequal standard of morals, even the mothers and children are destroyed by one of the vilest and most horrible

diseases that ravage humanity.

"There is only one way to put a stop to this agitation; there is only one way to break down this agitation. It is not by deporting us, it is not by locking us up in gaol; it is by doing us justice. And so I appeal to you gentlemen, in this case of mine, to give a verdict, not only on my case, but upon the whole of this agitation. I ask you to find me not guilty of malicious incitement to a breach of the law.

"These are my last words. My incitement is not malicious. If I had power to deal with these things, I would be in absolute obedience to the law. I would say to women, 'You have a constitutional means of getting redress for your grievances; use your votes, convince your fellow-voters of the righteousness of your demands. That is the way to obtain justice.' I am not guilty of malicious incitement, and I appeal to you, for the welfare of the country, for the welfare of the race, to return a verdict of not guilty in this case that you are called upon to try."

After recapitulating the charge the Judge, in summing up, said:

"It is scarcely necessary for me to tell you that the topics urged by the defendant in her address to you with regard to provocation by the laws of the country and the injustice done to women because they are not given the vote as men are, have no bearing upon the question you have to decide.

"The motive at the back of her mind, or at the back of the minds of those who actually did put the gunpowder there, would afford no defence to this indictment. I am quite sure you will deal with this case upon the evidence, and the evidence alone, without regard to any question as to whether you think the law is just or unjust. It has nothing to do with the case. I should think you will probably have no doubt that this defendant, if she did these things charged against her, is not actuated by the ordinary selfish motive that leads most of the criminals who are in this dock to commit the crimes that they do commit. She is none the less guilty if she did these things which are charged against her, although she believes that by means of this kind the condition of society will be altered."

The jury retired, and soon after the afternoon session of the court opened they filed in, and in reply to the usual question asked by the clerk of arraigns, said that they had agreed upon a verdict. Said the clerk:

"Do you find Mrs. Pankhurst guilty or not guilty?"

"Guilty," said the foreman, "with a strong recommendation to mercy."

I spoke once more to the Judge.

"The jury have found me guilty, with a strong recommendation to mercy, and I do not see, since motive is not taken into account in human laws, that they could do otherwise after your summing up. But since motive is not taken into account in human laws, and since I, whose motives are not ordinary motives, am about to be sentenced by you to the punishment which is accorded to people whose motives are selfish motives, I have only this to say: If it was impossible for a different verdict to be found; if it is your duty to sentence me, as it will be presently, then I want to say to you, as a private citizen, and to the jury as private citizens, that I, standing here, found guilty by the laws of my country, I say to you it is your duty, as private citizens, to do what you can to put an end to this intolerable state of affairs. I put that duty upon you. And I want to say, _whatever the sentence you pass upon me, I shall do what is humanly possible to terminate that sentence at the earliest possible moment. I have no sense of guilt. I feel I have done my duty. I look upon myself as a prisoner of war. I am under no moral obligation to conform to, or in any way accept, the sentence imposed upon me._ I shall take the desperate remedy that other women have taken. It is obvious to you that the struggle will be an unequal one, but I shall make it--I shall make it as long as I have an ounce of strength left in me, or any life left in me.

"I shall fight, I shall fight, I shall fight, from the moment I enter prison to struggle against overwhelming odds; I shall resist the doctors if they attempt to feed me. I was sentenced last May in this court to nine months' imprisonment. I remained in prison six weeks. There are people who have laughed at the ordeal of hunger-striking and forcible feeding. All I can say is, and the doctors can bear me out, that I was released because, had I remained there much longer, I should have been a dead woman.

"I know what it is because I have gone through it. My own daughter[4] has only just left it. There are women there still facing that ordeal, facing it twice a day. Think of it, my lord, twice a day this fight is gone through. Twice a day a weak woman resisting overwhelming force, fights and fights as long as she has strength left; fights against women and even against men, resisting with her tongue, with her teeth, this ordeal. Last night in the House of Commons some alternative was discussed, or rather, some additional punishment. Is it not a strange thing, my lord, that laws which have sufficed to restrain men throughout the history of this

country do not suffice now to restrain women--decent women, honourable women?

"Well, my lord, I do want you to realise it. I am not whining about my punishment, I invited it. I deliberately broke the law, not hysterically or emotionally, but of set serious purpose, because I honestly feel it is the only way. Now, I put the responsibility of what is to follow upon you, my lord, as a private citizen, and upon the gentlemen of the jury, as private citizens, and upon all the men in this court--what are you, with your political powers, going to do to end this intolerable situation?

"_To the women I have represented, to the women who, in response to my incitement, have faced these terrible consequences, have broken laws, to them, I want to say I am not going to fail them, but to face it as they face it, to go through with it, and I know that they will go on with the fight whether I live or whether I die._

"_This movement will go on and on until we have the rights of citizens in this country, as women have in our Colonies, as they will have throughout the civilised world before this woman's war is ended._

"That is all I have to say."

Mr. Justice Lush, in passing sentence, said: "It is my duty, Mrs. Emmeline Pankhurst, and a very painful duty it is, to pass what, in my opinion, is a suitable and adequate sentence for the crime of which you have been most properly convicted, having regard to the strong recommendation to mercy by the jury. I quite recognise, as I have already said, that the motives that have actuated you in committing this crime are not the selfish motives that actuate most of the persons who stand in your position, but although you blind your eyes to it, I cannot help pointing out to you that the crime of which you have been convicted is not only a very serious one, but, in spite of your motives, it is, in fact, a wicked one. It is wicked because it not only leads to the destruction of property of persons who have done you no wrong, but in spite of your calculations, it may expose other people to the danger of being maimed or even killed. It is wicked because you are, and have been, luring other people--young women, it may be--to engage in such crimes, possibly to their own ruin; and it is wicked, because you cannot help being alive to it if you would only think.

"You are setting an example to other persons who may have other grievances that they legitimately want to have put right by embarking on a similar scheme to yours, and trying to effect their object by attacking the property, if not the lives, of other people. I know, unfortunately--at least, I feel sure--you will pay no heed to what I say. I only beg of you to think of these things."

"I have thought of them," I interjected.

"Think, if only for one short hour, dispassionately," continued the majesty of law, "I can only say that, although the sentence I am going to pass must be a severe one, must be adequate to the crime of which you have been found guilty, if you would only realise the wrong you are doing, and the mistake you are making, and would see the error you have committed, and undertake to amend matters by using your influence in a right direction, I would be the first to use all my best endeavours to bring about a mitigation of the sentence I am about to pass.

"I cannot, and I will not, regard your crime as a merely trivial one. It is not. It is a most serious one, and, whatever you may think, it is a wicked one. I have paid regard to the recommendation of the jury. You yourself have stated the maximum sentence which this particular offence is by the legislature thought to deserve. The least sentence I can pass upon you is a sentence of three years' penal servitude."

As soon as the sentence was pronounced the intense silence which had reigned throughout the trial was broken, and an absolute pandemonium broke out among the spectators. At first it was merely a confused and angry murmur of "Shame!" "Shame!" The murmurs quickly swelled into loud and indignant cries, and then from gallery and court there arose a great chorus uttered with the utmost intensity and passion. "Shame!" "Shame!" The women sprang to their feet, in many instances stood on their seats, shouting "Shame!" "Shame!" as I was conducted out of the dock in charge of two wardresses. "Keep the flag flying!" shouted a woman's voice, and the response came in a chorus: "We will!" "Bravo!" "Three cheers for Mrs. Pankhurst!" That was the last I heard of the courtroom protest.

Afterwards I heard that the noise and confusion was kept up for several minutes longer, the Judge and the police being quite powerless to obtain order. Then the women filed out singing the Women's Marseillaise--

"March on, march on, Face to the dawn, The dawn of liberty."

The Judge flung after their retreating forms the dire threat of prison for any woman who dared repeat such a scene. Threat of prison--to Suffragettes! The women's song only swelled the louder and the corridors of Old Bailey reverberated with their shouts. Certainly that venerable building had never in its checkered history witnessed such a scene. The great crowd of detectives and police who were on duty seemed actually paralysed by the audacity of the protest, for they made no attempt to intervene.

At three o'clock, when I left the court by a side entrance in Newgate Street, I found a crowd of women waiting to cheer me. With the two wardresses I entered a four wheeler and was driven to Holloway to begin my hunger strike. Scores of women followed in taxicabs, and when I arrived at the prison gates there was another protest of cheers for the cause and boos for the law. In the midst of all this intense excitement I passed through the grim gates into the twilight of prison, now become a battle-ground.

FOOTNOTE:

[4] Sylvia Pankhurst, who was forcibly fed for five weeks, during an original sentence of two months imposed for breaking one window.

CHAPTER VI

Prison had indeed been for us a battle-ground ever since the time when we had solemnly resolved that, as a matter of principle, we would not submit to the rules that bound ordinary offenders against the law. But when I entered Holloway on that April day in 1913, it was with full knowledge that I had before me a far more prolonged struggle than any that the militant suffragists had hitherto faced. I have described the hunger strike, that terrible weapon with which we had repeatedly broken our prison bars. The Government, at their wits' end to cope with the hunger strikers, and to overcome a situation which had brought the laws of England into such scandalous disrepute, had had recourse to a measure, surely the most savagely devised ever brought before a modern Parliament.

In March of that year, while I was waiting trial on the charge of conspiring to destroy Mr. Lloyd-George's country house, a bill was introduced into the House of Commons by the Home Secretary, Mr. Reginald McKenna, a bill which had for its avowed object the breaking down of the hunger strike. This measure, now universally known as the "Cat and Mouse Act," provided that when a hunger striking suffrage prisoner (the law was frankly admitted to apply only to suffrage prisoners) was certified by the prison doctors to be in danger of death, she could be ordered released on a sort of a ticket of leave for the purpose of regaining strength enough to undergo the remainder of her sentence. Released, she was still a prisoner, the prisoner, or the patient, or the victim, as you may choose to call her, being kept under constant police surveillance. According to the terms of the bill the prisoner was released for a specified number of days, at the expiration of which she was supposed to return to prison on her own account. Says the Act:

"The period of temporary discharge may, if the Secretary of State thinks fit, be extended on a representation of the prisoner that the state of her health renders her unfit to return to prison. If such representation be made, the prisoner shall submit herself, if so required, for medical examination by the medical officer of the above mentioned prison, or other registered medical practitioner appointed by the Secretary of State.

The prisoner shall notify to the Commissioner of Police of the Metropolis the place of residence to which she goes on her discharge. She shall not change her residence without giving one clear day's notice in writing to the Commissioner, specifying the residence to which she is going and she shall not be temporarily absent from her residence for more than twelve hours without giving a like notice," etc.

The idea of militant suffragists respecting a law of this order is almost humorous, and yet the smile dies before the pity one feels for the Minister whose confession of failure is embodied in such a measure. Here was a mighty Government weakly resolved that justice to women it would not grant, knowing that submission of women it could not force, and so was willing to compromise with a piece of class legislation absolutely contrary to all of its avowed principles. Said Mr. McKenna, pleading in the House for the advancement of his odious measure: "At the present time I cannot make these prisoners undergo their sentences without serious risk of death and I want to have power to enable me to compel a prisoner to undergo the sentence, and I want that power in all cases where the prisoner adopts the system of the hunger strike. At the present moment, although I have the power of release, I cannot release a prisoner without a pardon, and I have to discharge them for good. I want the power of releasing a prisoner without a pardon, with the sentence remaining alive.... I want to enforce the Law, and I want, if I can, to enforce it without forcible feeding,

and without undergoing the risk of some one else's life."

Interrogated by several members, Mr. McKenna admitted that the "Cat and Mouse" bill, if passed, would not inevitably do away with forcible feeding, but he promised that the hateful and disgusting process would be resorted to only when "absolutely necessary." We shall see later how hypocritical this representation was.

Parliament, which had never had time to consider, beyond its initial stages, a women's suffrage measure, passed the Cat and Mouse Act through both houses within the limits of a few days. It was already law when I entered Holloway on April 3rd, 1913, and I grieve to state that many members of the Labour Party, pledged to support woman suffrage, helped to make it into law.

Of course the Act was, from its inception, treated by the suffragists with the utmost contempt. We had not the slightest intention of assisting Mr. McKenna in enforcing unjust sentences against soldiers in the army of freedom, and when the prison doors closed behind me I adopted the hunger strike exactly as though I expected it to prove, as formerly, a means of gaining my liberty.

That struggle is not a pleasant one to recall. Every possible means of breaking down my resolution was resorted to. The daintiest and most tempting food was placed in my cell. All sorts of arguments were brought to bear against me--the futility of resisting the Cat and Mouse Act, the wickedness of risking suicide--I shall not attempt to record all the arguments. They fell against a blank wall of consciousness, for my thoughts were all very far away from Holloway and all its torments. I knew, what afterwards I learned as a fact, that my imprisonment was followed by the greatest revolutionary outbreak that had been witnessed in England since 1832. From one end of the island to the other the beacons of the women's revolution blazed night and day. Many country houses--all unoccupied--were fired, the grand stand of Ayr race course was burned to the ground, a bomb was exploded in Oxted Station, London, blowing out walls and windows, some empty railroad carriages were blown up, the glass of thirteen famous paintings in the Manchester Art Gallery were smashed with hammers--these are simply random specimens of the general outbreak of secret guerilla warfare waged by women to whose liberties every other approach had been barricaded by the Liberal Government of free England. The only answer of the Government was the closing of the British Museum, the National Gallery, Windsor Castle, and other tourist resorts. As for the result on the people of England, that was exactly what we had anticipated. The public were thrown into a state of emotion of insecurity and frightened expectancy. Not yet did they show themselves ready to demand of the Government that the outrages be stopped in the only way they could be stopped--by giving votes to women. I knew that it would be so. Lying in my lonely cell in Holloway, racked with pain, oppressed with increasing weakness, depressed with the heavy responsibility of unknown happenings, I was sadly aware that we were but approaching a far goal. The end, though certain, was still distant. Patience, and still more patience, faith and still more faith, well, we had called upon these souls' help before and it was certain that they would not fail us at this greatest crisis of all.

Thus in great anguish of mind and body passed nine terrible days, each one longer and more acutely miserable than the preceding. Towards the last, I was mercifully half unconscious of my surroundings. A curious indifference took possession of my over-wrought mind, and it was almost without emotion that I heard, on the morning of the tenth day, that I was to be released temporarily in order to recover my health. The Governor came to my cell and read me my licence, which commanded me to return to Holloway in fifteen days, and meanwhile to observe all the obsequious terms as to informing the police of my movements. With what strength my hands retained I tore the document in strips and dropped it on the floor of the cell. "I have no intention," I said, "of obeying this infamous law. You release me knowing perfectly well that I shall never voluntarily return to any of your prisons."

They sent me away, sitting bolt upright in a cab, unmindful of the fact that I was in a dangerous condition of weakness, having lost two stone in weight and suffered seriously from irregularities of heart action. As I left the prison I was gratefully aware of groups of our women standing bravely at the gates, as though enduring a long vigil. As a matter of fact, relays of women had picketed the place night and day during the whole term of my imprisonment. The first pickets were arrested, but as others constantly arrived to fill their places the police finally gave in and allowed the women to march up and down before the prison carrying the flag.

At the nursing home to which I was conveyed I learned that Annie Kenney, Mrs. Drummond, and our staunch friend, Mr. George Lansbury,[5] had been arrested during my imprisonment, and that all three had adopted the hunger strike. I also learned on my own account how desperately the Government were striving to make their Cat and Mouse Act--the last stand in their losing campaign--a success. Without regard to the extra expense laid on the unfortunate tax payers of the country, the Government employed a large extra force of police especially for this purpose. As I lay in bed, being assisted by every medical resource to return to life and health, these special police, colloquially termed "Cats," guarded the nursing home as if it were a besieged castle. In the street under my windows two detectives and a constable stood on guard night and day. In a house at right angles to my refuge three more

detectives kept constant watch. In the mews at the rear of the house were more detectives, and diligently patrolling the road, as if in expectation of a rescuing regiment, two taxicabs, each with its quota of detectives, guarded the highways.

All this made recovery slow and difficult. But worse was to come. On April 30th, just as I was beginning to rally somewhat, came the news that the police had swooped down on our headquarters in Kingsway and had arrested the entire official force. Miss Barrett, associate editor of _The Suffragette_; Miss Lennox, the sub-editor; Miss Lake, business manager; Miss Kerr, office manager, and Mrs. Sanders, financial secretary of the Union, were arrested, although not one of them had ever appeared in any militant action. Mr. E. G. Clayton, a chemist, was also arrested, accused of furnishing the W. S. P. U. with explosive materials. The offices were thoroughly searched, and, as on a former occasion, stripped of all books and papers. While this was being done another party of police, armed with a special warrant, proceeded to the printing office where our paper, _The Suffragette_, was published. The printer, Mr. Drew, was placed under arrest and the material for the paper, which was to appear on the following day, was seized. By one o'clock in the afternoon the entire plant and the headquarters of the Union were in the hands of the police, and to all appearances the militant movement--temporarily at least--was brought to a full stop. In my state of semi-prostration it at first seemed to me best to let the week's issue of the paper lapse, but on second thought I decided that even the appearance of surrender was not to be thought of. How we managed it need not here be told, but we actually did, overnight, with hardly any material, except Christabel's leading article, and with hastily summoned helpers, get out the paper as usual, and side by side with the morning journals which bore front page stories of the suppression of the Suffragette organ, our paper sellers sold _The Suffragette_. The front page bore, instead of the usual cartoon, the single word in bold faced type--

"RAIDED,"

the full story of the police search and the arrests being related in the other pages. Our headquarters, I may say in passing, remained closed less than forty-eight hours. We are so organised that the arrest of leaders does not seriously cripple us. Every one has an understudy, and when one leader drops out her substitute is ready instantly to take her place.

In this emergency there appeared as chief organiser in Miss Kenney's place, Miss Grace Roe, one of the young Suffragettes of whom I, as belonging to the older generation, am so proud. Faced by difficulties as great as the Government could make them, Miss Roe at once showed herself to be equal to the situation, and to have the gift of unswerving loyalty combined with a strong and rapid judgment of things and people. Aiding her was Mrs. Dacre Fox, who surprised us all by her amazing ability to act as assistant editor of _The Suffragette_, manage a host of affairs in the office, and preside at our weekly meetings. Another member of the Union who came prominently to the front at the time of this crisis was Mrs. Mansel.

In two days' time the office was open and running quite as usual, no outward sign showing the grief and indignation felt for our imprisoned comrades. Most of them refused bail and instantly hunger struck appearing in court for trial three days later in a pitiful state. Mrs. Drummond was so obviously ill and in need of medical attention that she was discharged and was very soon afterwards operated upon. Mr. Drew, the printer, was forced to sign an undertaking not to publish the paper again. The others were sentenced to terms varying from six to eighteen months. Mr. Clayton was sentenced to twenty-one months, and after desperate resistance, during which he was forcibly fed many times, escaped his prison. The others, following the same example, starved their way to liberty, and have ever since been pursued at intervals and rearrested under the Cat and Mouse Act.

After my discharge, April 12th, I remained in the nursing home until partially restored, then, under the eyes of the police, I motored out to Woking, the country home of my friend, Dr. Ethel Smyth. This house, like the nursing home, was guarded by a small army of police. I never went to the window, I never took the air in the garden without being conscious of watching eyes. The situation became intolerable, and I determined to end it. On May 26th there was a great meeting at the London Pavillion, and I gave notice that I would attend it. Supported by Dr. Flora Murray, Dr. Ethel Smyth and my devoted Nurse Pine, I walked downstairs, to be confronted at the door by a detective, who demanded to know where I was going. I was in a weak state, much weaker than I had imagined, and in refusing the right of a man to question my movements I exhausted the last remnant of my strength and sank fainting in the arms of my friends. As soon as I recovered I got into the motor car. The detective instantly took his place beside me and told the chauffeur to drive to Bow Street Station. The chauffeur replied that he took his orders only from Mrs. Pankhurst, whereupon the detective summoned a taxicab and, placing me under arrest, took me to Bow Street.

Under the Cat and Mouse Act a paroled prisoner can be thus arrested without the formality of a warrant, nor does the time she has spent at liberty, in regaining her health, count off from her prison sentence. The magistrate at Bow Street was therefore quite within his legal rights when he ordered me returned to Holloway. I felt it my duty, nevertheless, to point out to him the inhumanity of his

act. I said to him: "I was released from Holloway on account of my health. Since then I have been treated exactly as if I were in prison. It has become absolutely impossible for any one to recover health under such conditions, and this morning I decided to make this protest against a state of affairs unparalleled in a civilised country."

[Illustration: RE-ARREST OF MRS. PANKHURST AT WOKING

May 26, 1913]

The magistrate replied formally: "You quite understand what the position is. You have been arrested on this warrant and all I have to do is to make an order recommending you to prison."

"I think" I said, "that you should do so, with a full sense of responsibility. If I am taken to Holloway on your warrant I shall resume the protest I made before which led to my release, and I shall go on indefinitely until I die, or until the Government decide, since they have taken upon themselves to employ you and other people to administer the laws, that they must recognise women as citizens and give them some control over the laws of this country."

It was a five days' hunger strike this time, because the extreme weakness of my condition made it impossible for me to endure a longer term. I was released on May 30th on a seven days' licence, and in a half-alive state was again carried to a nursing home. Less than a week later, while I was still bed-ridden, a terrible event occurred, one that should have shaken the stolid British public into a realisation of the seriousness of the situation precipitated by the Government. Emily Wilding Davison, who had been associated with the militant movement since 1906, gave up her life for the women's cause by throwing herself in the path of the thing, next to property, held most sacred to Englishmen--sport. Miss Davison went to the races at Epsom, and breaking through the barriers which separated the vast crowds from the race course, rushed in the path of the galloping horses and caught the bridle of the King's horse, which was leading all the others. The horse fell, throwing his jockey and crushing Miss Davison in such shocking fashion that she was carried from the course in a dying condition. Everything possible was done to save her life. The great surgeon, Mr. Mansell Moullin, put everything aside and devoted himself to her case, but though he operated most skilfully, the injuries she had received were so frightful that she died four days later without once having recovered consciousness. Members of the Union were beside her when she breathed her last, on June 8th, and on June 14th they gave her a great public funeral in London. Crowds lined the streets as the funeral car, followed by thousands of women, passed slowly and sadly to St. George's Church, Bloomsbury, where the memorial services were held.

Emily Wilding Davison was a character almost inevitably developed by a struggle such as ours. She was a B. A. of London University, and had taken first class honours at Oxford in English Language and Literature. Yet the women's cause made such an appeal to her reason and her sympathies that she put every intellectual and social appeal aside and devoted herself untiringly and fearlessly to the work of the Union. She had suffered many imprisonments, had been forcibly fed and most brutally treated. On one occasion when she had barricaded her cell against the prison doctors, a hose pipe was turned on her from the window and she was drenched and all but drowned in the icy water while workmen were breaking down her cell door. Miss Davison, after this experience, expressed to several of her friends the deep conviction that now, as in days called uncivilised, the conscience of the people would awaken only to the sacrifice of a human life. At one time in prison she tried to kill herself by throwing herself head-long from one of the upper galleries, but she succeeded only in sustaining cruel injuries. Ever after that time she clung to her conviction that one great tragedy, the deliberate throwing into the breach of a human life, would put an end to the intolerable torture of women. And so she threw herself at the King's horse, in full view of the King and Queen and a great multitude of their Majesties' subjects, offering up her life as a petition to the King, praying for the release of suffering women throughout England and the world. No one can possibly doubt that that prayer can forever remain unanswered, for she took it straight to the Throne of the King of all the worlds.

The death of Miss Davison was a great shock to me and a very great grief as well, and although I was scarcely able to leave my bed I determined to risk everything to attend her funeral. This was not to be, however, for as I left the house I was again arrested by detectives who lay in waiting. Again the farce of trying to make me serve a three years' sentence was undertaken. But now the militant women had discovered a new and more terrible weapon with which to defy the unjust laws of England, and this weapon--the thirst strike--I turned against my gaolers with such effect that they were forced within three days to release me.

The hunger strike I have described as a dreadful ordeal, but it is a mild experience compared with the thirst strike, which is from beginning to end simple and unmitigated torture. Hunger striking reduces a prisoner's weight very quickly, but thirst striking reduces weight so alarmingly fast that prison doctors were at first thrown into absolute panic of fright. Later they became somewhat

hardened, but even now they regard the thirst strike with terror. I am not sure that I can convey to the reader the effect of days spent without a single drop of water taken into the system. The body cannot endure loss of moisture. It cries out in protest with every nerve. The muscles waste, the skin becomes shrunken and flabby, the facial appearance alters horribly, all these outward symptoms being eloquent of the acute suffering of the entire physical being. Every natural function is, of course, suspended, and the poisons which are unable to pass out of the body are retained and absorbed. The body becomes cold and shivery, there is constant headache and nausea, and sometimes there is fever. The mouth and tongue become coated and swollen, the throat thickens and the voice sinks to a thready whisper.

When, at the end of the third day of my first thirst strike, I was sent home I was in a condition of jaundice from which I have never completely recovered. So badly was I affected that the prison authorities made no attempt to arrest me for nearly a month after my release. On July 13th I felt strong enough once more to protest against the odious Cat and Mouse Act, and, with Miss Annie Kenney, who was also at liberty "on medical grounds," I went to a meeting at the London Pavillion. At the close of the meeting, during which Miss Kenney's prison licence was auctioned off for L12, we attempted for the first time the open escape which we have so frequently since effected. Miss Kenney, from the platform, announced that we should openly leave the hall, and she forthwith walked coolly down into the audience. The police rushed in in overwhelming numbers, and after a desperate fight, succeeded in capturing her. Other detectives and policemen hurried to the side door of the hall to intercept me, but I disappointed them by leaving by the front door and escaping to a friend's house in a cab.

The police soon traced me to the house of my friend, the distinguished scientist, Mrs. Hertha Ayrton, and the place straightway became a besieged fortress. Day and night the house was surrounded, not only by police, but by crowds of women sympathisers. On the Saturday following my appearance at the Pavillion we gave the police a bit of excitement of a kind they do not relish. A cab drove up to Mrs. Ayrton's door, and several well-known members of the Union alighted and hurried indoors. At once the word was circulated that a rescue was being attempted, and the police drew resolutely around the cab. Soon a veiled woman appeared in the doorway, surrounded by Suffragettes, who, when the veiled lady attempted to get into the cab, resisted with all their strength the efforts of the police to lay hands upon her. The cry went up from all sides: "They are arresting Mrs. Pankhurst!" Something very like a free fight ensued, occupying all the attention of the police who were not in the immediate vicinity of the cab. The men surrounding that rocking vehicle succeeded in tearing the veiled figure from the arms of the other women and piling into the cab ordered the chauffeur to drive full speed to Bow Street. Before they reached their destination, however, the veiled lady raised her veil--alas, it was not Mrs. Pankhurst, who by that time was speeding away in another taxicab in quite another direction.

Our ruse infuriated the police, and they determined to arrest me at my first public appearance, which was at the Pavillion on the Monday following the episode just related. When I reached the Pavillion I found it literally surrounded by police, hundreds of them. I managed to slip past the outside cordon, but Scotland Yard had its best men inside the hall, and I was not permitted to reach the platform. Surrounded by plain clothes men, batons drawn, I could not escape, but I called out to the women that I was being taken, and so valiantly did they rush to the rescue that the police had their hands full for nearly half an hour before they got me into a taxicab bound for Holloway. Six women were arrested that day, and many more than six policemen were temporarily incapacitated for duty.

By this time I had made up my mind that I would not only resist staying in prison, I would resist to the utmost of my ability going to prison. Therefore, when we reached Holloway I refused to get out of the cab, declaring to my captors that I would no longer acquiesce in the slow judicial murder to which the Government were subjecting women. I was lifted out and carried into a cell in the convicted hospital wing of the gaol. The wardresses who were on duty there spoke with some kindness to me, suggesting that, as I was very apparently exhausted and ill, I should do well to undress and go to bed. "No," I replied, "I shall not go to bed, not once while I am kept here. I am weary of this brutal game, and I intend to end it."

Without undressing, I lay down on the outside of the bed. Later in the evening the prison doctor visited me, but I refused to be examined. In the morning he came again, and with him the Governor and the head wardress. As I had taken neither food nor water since the previous day my appearance had become altered to such an extent that the doctor was plainly perturbed. He begged me, "as a small concession," to allow him to feel my pulse, but I shook my head, and they left me alone for the day. That night I was so ill that I felt some alarm for my own condition, but I knew of nothing that could be done except to wait. On Wednesday morning the Governor came again and asked me with an assumption of carelessness if it were true that I was refusing both food and water. "It is true," I said, and he replied brutally: "You are very cheap to keep." Then, as if the thing were not a ridiculous farce, he announced that I was sentenced to close confinement for three days, with deprivation of all privileges, after which he left my cell.

Twice that day the doctor visited me, but I would not allow him to touch me. Later came a medical officer from the Home Office, to which I had complained, as I had complained to the Governor and the prison doctor, of the pain I still suffered from the rough treatment I had received at the Pavillion. Both of the medical men insisted that I allow them to examine me, but I said: "I will not be examined by you because your intention is not to help me as a patient, but merely to ascertain how much longer it will be possible to keep me alive in prison. I am not prepared to assist you or the Government in any such way. I am not prepared to relieve you of any responsibility in this matter." I added that it must be quite obvious that I was very ill and unfit to be confined in prison. They hesitated for a moment or two, then left me.

Wednesday night was a long nightmare of suffering, and by Thursday morning I must have presented an almost mummified appearance. From the faces of the Governor and the doctor when they came into my cell and looked at me I thought that they would at once arrange for my release. But the hours passed and no order for release came. I decided that I must force my release, and I got up from the bed where I had been lying and began to stagger up and down the cell. When all strength failed me and I could keep my feet no longer I lay down on the stone floor, and there, at four in the afternoon, they found me, gasping and half unconscious. And then they sent me away. I was in a very weakened condition this time, and had to be treated with saline solutions to save my life. I felt, however, that I had broken my prison walls for a time at least, and so this proved. It was on July 24th that I was released. A few days later I was borne in an invalid's chair to the platform of the London Pavillion. I could not speak, but I was there, as I had promised to be. My licence, which by this time I had ceased to tear up because it had an auction value, was sold to an American present for the sum of one hundred pounds. I had told the Governor on leaving that I intended to sell the licence and to spend the money for militant purposes, but I had not expected to raise such a splendid sum as one hundred pounds. I shall always remember the generosity of that unknown American friend.

A great medical congress was being held in London in the summer of 1913, and on August 11th we held a large meeting at Kingsway Hall, which was attended by hundreds of visiting doctors. I addressed this meeting, at which a ringing resolution against forcible feeding was passed, and I was allowed to go home without police interference. It was, as a matter of fact, the second time during that month that I had spoken in public without molestation. The presence of so many distinguished medical men in London may have suggested to the authorities that I had better be left alone for the time being. At all events I was left alone, and late in the month I went, quite publicly, to Paris, to see my daughter Christabel and plan with her the campaign for the coming autumn. I needed rest after the struggles of the past five months, during which I had served, of my three years' prison sentence, not quite three weeks.

FOOTNOTE:

[5] Mr. Lansbury shortly before this had resigned his seat in Parliament and had gone to his constituents on the question of women's suffrage. Both the Liberal and the Conservative parties had united against him, with the result that a Unionist candidate was returned in his place. Mr. Lloyd-George publicly rejoiced in the result of this election, saying that Mr. Marsh, the Conservative candidate, had been his man. The Labour Party, in Parliament and out, meekly accepted this piece of Liberal chicanery without protest.

CHAPTER VII

The two months of the summer of 1913 which were spent with my daughter in Paris were almost the last days of peace and rest I have been destined since to enjoy. I spent the days, or some hours of them, in the initial preparation of this volume, because it seemed to me that I had a duty to perform in giving to the world my own plain statement of the events which have led up to the women's revolution in England. Other histories of the militant movement will undoubtedly be written; in times to come when in all constitutional countries of the world, women's votes will be as universally accepted as men's votes are now; when men and women occupy the world of industry on equal terms, as co-workers rather than as cut-throat competitors; when, in a word, all the dreadful and criminal discriminations which exist now between the sexes are abolished, as they must one day be abolished, the historian will be able to sit down in leisurely fashion and do full justice to the strange story of how the women of England took up arms against the blind and obstinate Government of England and fought their way to political freedom. I should like to live long enough to read such a history, calmly considered, carefully analysed, conscientiously set forth. It will be a better book to read than this one, written, as it were, in camp between battles. But perhaps this one, hastily prepared as it has been, will give the reader of the future a clearer impression of the strenuousness and the desperation of the conflict, and also something of the heretofore undreamed of courage and fighting strength of women, who, having learned the joy of battle, lose all sense of fear and continue their struggle up to and

past the gates of death, never flinching at any step of the way.

Every step since that meeting in October, 1912, when we definitely declared war on the peace of England, has been beset with danger and difficulty, often unexpected and undeclared. In October, 1913, I sailed in the French liner, _La Provence_, for my third visit to the United States. My intention was published in the public press of England, France and America. No attempt at concealment of my purpose was made, and in fact, my departure was witnessed by two men from Scotland Yard. Some hints had reached my ears that an attempt would be made by the Immigration Officers at the port of New York to exclude me as an undesirable alien, but I gave little credit to these reports. American friends wrote and cabled encouraging words, and so I passed my time aboard ship quite peacefully, working part of the time, resting also against the fatigue always attendant on a lecture tour.

[Illustration: MRS. PANKHURST AND CHRISTABEL IN THE GARDEN OF CHRISTABEL'S HOME IN PARIS]

We came to anchor in the harbour of New York on October 26th, and there, to my astonishment, the Immigration authorities notified me that I was ordered to Ellis Island to appear before a Board of Special Inquiry. The officers who served the order of detention did so with all courtesy, even with a certain air of reluctance. They allowed my American travelling companion, Mrs. Rheta Childe Dorr, to accompany me to the Island, but no one, not even the solicitor sent by Mrs. O. H. P. Belmont to defend me, was permitted to attend me before the Board of Special Inquiry. I went before these three men quite alone, as many a poor, friendless woman, without any of my resources, has had to appear. The moment of my entrance to the room I knew that extraordinary means had been employed against me, for on the desk behind which the Board sat I saw a complete _dossier_ of my case in English legal papers. These papers may have been supplied by Scotland Yard, or they may have been supplied by the Government. I cannot tell, of course. They sufficed to convince the Board of Special Inquiry that I was a person of doubtful character, to say the least of it, and I was informed that I should have to be detained until the higher authorities at Washington examined my case. Everything was done to make me comfortable, the rooms of the Commissioner of Immigration being turned over to me and my companion. The very men who found me guilty of moral obloquy--something of which no British jury has ever yet accused me--put themselves out in a number of ways to make my detention agreeable. I was escorted all over the Island and through the quarters assigned detained immigrants, whose right to land in the United States is in question. The huge dining-rooms, the spotless kitchens and the admirably varied bill of fare interested and impressed me. Nothing like them exists in any English institution.

I remained at Ellis Island two and a half days, long enough for the Commissioner of Immigration at Washington to take my case to the President who instantly ordered my release. Whoever was responsible for my detention entirely overlooked the advertising value of the incident. My lecture tour was made much more successful for it and I embarked for England late in November with a very generous American contribution to our war chest, a contribution, alas, that I was not permitted to deliver in person.

The night before the White Star liner _Majestic_ reached Plymouth a wireless message from headquarters informed me that the Government had decided to arrest me on my arrival. The arrest was made, under very dramatic conditions, the next day shortly before noon. The steamer came to anchor in the outer harbour, and we saw at once that the bay, usually so animated with passing vessels, had been cleared of all craft. Far in the distance the tender, which on other occasions had always met the steamer, rested at anchor between two huge grey warships. For a moment or two the scene halted, the passengers crowding to the deckrails in speechless curiosity to see what was to happen next. Suddenly a fisherman's dory, power driven, dashed across the harbour, directly under the noses of the grim war vessels. Two women, spray drenched, stood up in the boat, and as it ploughed swiftly past our steamer the women called out to me: "The Cats are here, Mrs. Pankhurst! They're close on you--" Their voices trailed away into the mist and we heard no more. Within a minute or two a frightened ship's boy appeared on deck and delivered a message from the purser asking me to step down to his office. I answered that I would certainly do nothing of the kind, and next the police swarmed out on deck and I heard, for the fifth time that I was arrested under the Cat and Mouse Act. They had sent five men from Scotland Yard, two men from Plymouth and a wardress from Holloway, a sufficient number, it will be allowed, to take one woman from a ship anchored two miles out at sea.

Following my firm resolve not to assist in any way the enforcing of the infamous law, I refused to go with the men, who thereupon picked me up and carried me to the waiting police tender. We steamed some miles up the Cornish coast, the police refusing absolutely to tell me whither they were conveying me, and finally disembarked at Bull Point, a Government landing-stage, closed to the general public. Here a motor car was waiting, and accompanied by my bodyguard from Scotland Yard and Holloway, I was driven across Dartmoor to Exeter, where I had a not unendurable imprisonment and hunger strike of four days. Everyone from the Governor of the prison to the wardresses were openly sympathetic and kind, and I was told by one confidential official that they kept me only because they had orders to do so until after the great meeting at Empress Theatre, Earls Court, London, which had

been arranged as a welcome home for me. The meeting was held on the Sunday night following my arrest, and the great sum of L15,000 was poured into the coffers of militancy. This included the L4,500 which had been collected during my American tour.

Several days after my release from Exeter I went openly to Paris to confer with my daughter on matters relating to the campaign about to open, returning to attend a W. S. P. U. meeting on the day before my license expired. Nevertheless the boat train carriage in which I travelled with my doctor and nurse was invaded at Dover town by two detectives who told me to consider myself under arrest. We were making tea when the men entered, but this we immediately threw out of the window, because a hunger strike always began at the instant of arrest. We never compromised at all, but resisted from the very first moment of attack.

The reason for this uncalled for arrest at Dover was the fear on the part of the police of the body guard of women, just then organised for the expressed purpose of resisting attempts to arrest me. That the police, as well as the Government were afraid to risk encountering women who were not afraid to fight we had had abundant testimony. We certainly had it on this occasion, for knowing that the body guard was waiting at Victoria Station, the authorities had cut off all approaches to the arrival platform and the place was guarded by battalions of police. Not a passenger was permitted to leave a carriage until I had been carried across the arrival platform between a double line of police and detectives and thrown into a forty horse power motor car, guarded within by two plain clothes men and a wardress, and without by three more policemen. Around this motor car were twelve taxi-cabs filled with plain clothes men, four to each vehicle, and three guarding the outside, not to mention the driver, who was also in the employ of the police department. Detectives on motor cycles were on guard at various points ready to follow any rescuing taxicab.

Arrived at Holloway I was again lifted from the car and taken to the reception room and placed on the floor in a state of great exhaustion. When the doctor came in and told me curtly to stand up I was obliged to tell him that I could not stand. I utterly refused to be examined, saying that I was resolved to make the Government assume full responsibility for my condition. "I refuse to be examined by you or any prison doctor," I declared, "and I do this as a protest against my sentence, and against my being here at all. I no longer recognise a prison doctor as a medical man in the proper sense of the word. I have withdrawn my consent to be governed by the rules of prison; I refuse to recognise the authority of any prison official, and I therefore make it impossible for the Government to carry out the sentence they have imposed upon me."

Wardresses were summoned, I was placed in an invalid chair and so carried up three flights of stairs and put into an unwarmed cell with a concrete floor. Refusing to leave the chair I was lifted out and placed on the bed, where I lay all night without removing my coat or loosening my garments. It was on a Saturday that the arrest had been made, and I was kept in prison until the following Wednesday morning. During all that time no food or water passed my lips, and I added to this the sleep strike, which means that as far as was humanly possible I refused all sleep and rest. For two nights I sat or lay on the concrete floor, resolutely refusing the oft repeated offers of medical examination. "You are not a doctor," I told the man. "You are a Government torturer, and all you want to do is to satisfy yourself that I am not quite ready to die." The doctor, a new man since my last imprisonment, flushed and looked extremely unhappy. "I suppose you do think that," he mumbled.

On Tuesday morning the Governor came to look at me, and no doubt I presented by that time a fairly bad appearance. At least I gathered as much from the alarmed expression of the wardress who accompanied him. To the Governor I made the simple announcement that I was ready to leave prison and that I intended to leave very soon, dead or alive. I told him that from that moment I should not even rest on the concrete floor, but should walk my cell until I was released or until I died from exhaustion. All day I kept to this resolution, pacing up and down the narrow cell, many times stumbling and falling, until the doctor came in at evening to tell me that I was ordered released on the following morning. Then I loosened my gown and lay down, absolutely spent, and fell almost instantly into a death-like sleep. The next morning a motor ambulance took me to the Kingsway headquarters where a hospital room had been arranged for my reception. The two imprisonments in less than ten days had made terrible drafts on my strength, and the coldness of the Holloway cell had brought on a painful neuralgia. It was many days before I recovered even a tithe of my usual health.

These two arrests resulted exactly as the Government should have known that they would result, in a great outbreak of fresh militancy. As soon as the news spread that I had been taken at Plymouth a huge fire broke out in the timber yards at Richmond Walk, Devenport, and an acre and a half of timber, beside a pleasure fair and a scenic railway adjacent, to the value of thousands of pounds was destroyed. No one ever discovered the cause of the fire, the greatest that ever occurred in the neighbourhood, but tied to one of the railings was a copy of the _Suffragette_ and to another railing two cards, on one of which was written a message to the Government: "How dare you arrest Mrs. Pankhurst and allow Sir Edward Carson and Mr. Bonar Law to go free?" The second card bore the words: "Our reply to the torture of Mrs. Pankhurst, and her cowardly arrest at Plymouth."

Besides this fire, which waged fiercely from midnight until dawn, a large unoccupied house at Bristol was destroyed by fire; a fine residence in Scotland, also unoccupied, was badly damaged by fire; St. Anne's Church in a suburb of Liverpool was partly destroyed; and many pillar boxes in London, Edinburgh, Derby and other cities were fired. In churches all over the Kingdom our women created consternation by interpolating into the services reverently spoken prayers for prisoners who were suffering for conscience' sake. The reader no doubt has heard of these interruptions, and if so he has read of brawling, shrieking women, breaking into the sanctity of religious services, and creating riot in the House of God. I think the reader should know exactly what does happen when militants, who are usually religious women, interrupt church services. On the Sunday when I was in Holloway, following my arrest at Dover, certain women attending the afternoon service at Westminster Abbey, chanted in concert the following prayer: "God save Emmeline Pankhurst, help us with Thy love and strength to guard her, spare those who suffer for conscience' sake. Hear us when we pray to Thee." They had hardly finished this prayer when vergers fell upon them and with great violence hustled them out of the Abbey. One kneeling man, who happened to be near one of the women, forgot his Christian intercessions long enough to beat her in the face with his fists before the vergers came.

Similar scenes have taken place in churches and cathedrals throughout England and Scotland, and in many instances the women have been most barbarously treated by vergers and members of the congregations. In other cases the women not only have been left unmolested, but have been allowed to finish their prayers amid deep and sympathetic silence. Some clergymen have even been brave enough to add a reverent amen to these prayers for women in prison, and it has happened that clergymen have voluntarily offered prayers for us. The Church as a whole, however, has undoubtedly failed to live up to its obligation to demand justice for women, and to protest against the torture of forcible feeding. During the year just closing we sent many deputations to Church authorities, the Bishops, one after another having been visited in this manner. Some of the Bishops, including the reactionary Archbishop of Canterbury, refused to accord the desired interview, and when that happened, the answer of the deputation was to sit on the doorstep of the episcopal residence until surrender followed--as it invariably did.

As Holloway Gaol is within his diocese, the Bishop of London was visited by the W. S. P. U. and the demand was made that the Bishop himself should witness forcible feeding in order to realise the horror of the proceeding. He did visit two of the tortured women, but he did not see them forcibly fed, and when he came out he gave the public an account of his interview with them which was in effect the Government's version of the facts. The W. S. P. U. was naturally indignant, while all the Government's friends hailed the Bishop as a supporter of the policy of torture. Only those who have suffered the pain and agony, not to speak of the moral humiliation of forcible feeding can realise the depths of the iniquity which the Bishop of London was manoeuvred by the Govern

PART VIII.

THE AQUEDUCTS.

THE ARCHÆOLOGY OF ROME,

BY JOHN HENRY PARKER, C.B. HON. M.A. OXON., F.S.A. LOND.; KEEPER OF THE ASHMOLEAN MUSEUM OF HISTORY AND ARCHÆOLOGY, OXFORD; VICE-PRESIDENT OF THE OXFORD ARCHITECTURAL AND HISTORICAL SOCIETY, AND OF THE BRITISH AND AMERICAN ARCHÆOLOGICAL SOCIETY OF ROME; MEMBER OF THE ROYAL ARCHÆOLOGICAL INSTITUTE, MEMBRE DE LA SOCIETÉ FRANÇAISE D'ARCHÉOLOGIE, HONORARY MEMBER OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS, AND OF VARIOUS ARCHÆOLOGICAL SOCIETIES, ENGLISH AND FOREIGN.

THE AQUEDUCTS.

=OXFORD:= JAMES PARKER AND CO. =LONDON:= JOHN MURRAY, ALBEMARLE-STREET. 1876.

[Illustration]

THE AQUEDUCTS.

PREFACE TO THE AQUEDUCTS.

It is impossible to understand the archæology of Rome without studying the Aqueducts. In every part of the City, and of the country round it, there are remains of them; they are frequently mistaken for something else, and called by other names, misleading those who have not given attention to the subject. They are necessarily mixed up with the _Thermæ_, for most of the aqueducts were made to bring water to those great establishments. There was also a reservoir of water supplied by the aqueducts under each of the palaces, larger houses and villas, as may be seen in many parts of the Palatine, under the palaces of the Cæsars. In their original state the Aqueducts must have been among the grandest objects in Rome, and the most conspicuous in all directions. The principal approach from the east passed between two fine arcades of the aqueducts, one carrying three of them, the other two. These two fine arcades were not more than a hundred yards apart; all the great roads from the eastern side were brought into this space, and certainly, for the last mile into Rome, must have had one of these arcades on either hand: to the left, or south, the Claudian arcade, fifty feet high; to the right, the Marcian, thirty feet high.

For the last half-mile, the Claudian arcade was also the boundary of the palace gardens of the Sessorium, the residence first of the Kings and afterwards of one branch of the imperial family (that of Verus or Varius), who resided there for more than a century. That portion of the arcade still exists for a considerable extent, forming the northern wall of that garden, and at the same time part of the wall of the city, Aurelian having adopted it, and incorporated it with his great wall. This portion is thoroughly shewn in my Photographs, as it is a very important part of the antiquities of Rome, and illustrates many points. It was the place where the principal aqueducts entered Rome, and the whole ground is full of remains of them with their reservoirs and filtering-places. The inner side of the wall is the part necessarily shewn, because the outer side is concealed by the arcade of the Aqua Felice, excepting in places where the _specus_ of the Claudia and the Anio Novus appear above it. Just outside of this garden, at the west end of it, is the great foss which separated the Sessorium, or fortified palace, from the other fortifications of the City, and in it are remains of the two great reservoirs that were probably the Gemelli or Twins of Frontinus, made originally for the Appia and the Anio Vetus side by side, and used afterwards to receive the surplus water of the later aqueducts on a higher level. We then have a considerable number of the Arches of Nero, following a straight line for another mile to the west end of the Cœlian Hill; where remains of the great reservoir are on a level with the _specus_ carried on the top of this arcade, fifty feet above the ground in that high situation, from which the water was distributed in all directions, first on other arcades, three of which branched off from this point, and afterwards in metal pipes when it was sub-divided; but for the main supply no metal pipes then to be had were large and

strong enough to bear the pressure of a stream of water four feet deep and two feet wide, running at the rate of five or six miles an hour, if not more. The direct line went on over the Palatine to the Capitol, passing over the Forum Romanum on the bridge of Caligula, of which, also, some remains are shewn in my Photographs; the other two branches from the great reservoir over the Arch of Dolabella, went one to the right to the Colosseum (to supply the Stagna there), the other to the left to the Aventine, to supply the private house of Trajan and the Thermæ of Sura.

The Porta Maggiore stood at the end of the long vista between the two great aqueducts, and was itself made out of two of the arches of the Claudian arcade, in the last of the angles that occurred at every half-mile. The penultimate one was at the eastern end of the Sessorium palace gardens, where this water entered Rome, and then, after passing the angle to the north, with the usual _piscina_ and _castellum aquæ_, or reservoir and filtering-place, turned again to the west, as far as that gate where the Claudian arcade terminated. From this point the Marcian turned to the north upon the great bank of earth which formed the outer defence of Rome in that part, and continued along it for another half-mile, as far as the Porta di S. Lorenzo, and beyond it to the Prætorian Camp; then turning again to the west, it went across the great inner foss between the outer bank, the great _agger_ of Servius Tullius, which formed the inner line, where remains of it were found near the railway station in 1871, with inscriptions on two of the _cippi_, stating that the three aqueducts passed there. It is not quite correct to say that the _arcades_ were carried there, because where the ground is high the _specus_ are carried underground. This is the case between the Porta Maggiore (the Porta Esquilina of Frontinus) and the Porta di S. Lorenzo (the Porta Viminalis of the same). The _specus_ is seen on arches close to each of the gates; but, between the two, it passed underground through a sort of hillock, about midway between the two gates, as is mentioned by Frontinus. The ground is high again near the Porta Chiusa at the Prætorian Camp, and in the great bank or _agger_ of Servius Tullius.

These two great arcades are those chiefly known to visitors to Rome as THE AQUEDUCTS; but the underground aqueducts are at least equally interesting when understood. The Anio Vetus being near the surface can be traced all over Rome; the Appia being very deep, is not so easily traced, and can only be seen with certainty near its source and its mouth. There are other arcades nearly as fine as these; but, as they do not come so near Rome, they are less known; in the parts nearest to the City they are either underground or destroyed. One of them is that called Alexandrina by Fabretti; but the original parts of it are of the time of Hadrian and Trajan. This runs from the source near Gabii and Labicum, now la Colonna, to the place called _Cento-Celle_. Possibly some of the hundred cells or vaults found there and supposed to have been all tombs, were really reservoirs of water. At every great villa there are always remains of these great cisterns for the supply of water, and this is about three miles from Rome, where a great villa of Hadrian was situated. This arcade extends for miles across the country between the two great roads, one from Gabii, the other from Preneste (now Palestrina). Another fine arcade is seen on the road to Albano, at the Tor di Mezza Via (or half-way house). This has been ascertained to be the Aqua Aurelia, which goes to the villa of the Quintilii on the Via Appia, and from thence into Rome to supply the Thermæ of Commodus and Severus, of which also remains have been found; the latter part of its course is chiefly underground.

It was very difficult at first to ascertain to which of the aqueducts each of the remains belonged that were seen on all sides; and I found it necessary to follow each aqueduct up to its source, and then down to its mouth, in order to ascertain this. This work has taken me some years, in connection with the other branches of the general subject of the Archæology of Rome. It has now been done, with one exception,—the aqueduct made to bring water to the Thermæ of Diocletian on the Viminal,—which has not been traced; but there is great probability that it was a branch from one of the older aqueducts, probably brought across from the great reservoir where the Nymphæum of Alexander Severus was situated, on which the Trophies of Marius were hung. This is on high ground, and at a short distance only, so that it would be very convenient for the purpose. We see that there are several branches from that point, and one of them probably supplied these great Thermæ, for which purpose more than one aqueduct would be tapped. It may be that the curious sort of tower reservoir—long supposed to have been a tomb, a short distance to the south of the Trophies of Marius—was the one for these Thermæ; in either case, these reservoirs were supplied from the great old aqueducts.

I may almost say that wherever the aqueducts are visible, they can now be seen in my Photographs, and in some places the remains have been destroyed since these were taken, during what is called the _Restoration_ of the City Walls. Perhaps the finest and most interesting part of the Aqueducts are the great cascades at the source of the Anio Novus above Subiaco, in the bed of that river, situated in some of the finest scenery in the world. Among later works the ingenious manner in which the bed of the small river Almo is made use of to carry the water of two other mountain streams, the Aqua Crabra and the Marrana, the water of which never fails; and the manner in which the tunnel of the Aqua Julia has been used again in the twelfth century, are the most curious and interesting. This had hitherto escaped observation, and was not easily traced. The Aqua Felice was unfortunately carried out in

a very rude manner; the plan of the Pope was a good one, but was spoiled by the ignorance of the engineer.

The new aqueduct, the Aqua Marcia-Pia, restoring the celebrated Aqua Marcia to use in Rome, is a work deserving of high commendation. It is much to be regretted that my lamented friend the late Mr. Shepherd, to whose energy and perseverance we are chiefly indebted for this, did not live to see the completion of his work. Much credit is also due to Signor Moraldi, the originator of the scheme, to whom the Company still pay a premium, which he well deserves. His map[1] of the Aqua Marcia, of which he kindly gave me a photograph, was of great service to me, as far as it went; but I saw it was necessary to go further, and include all the Aqueducts on the eastern side of Rome. I was fortunate in meeting with Dr. Fabio Gori, who is a native of Subiaco, and has been interested in the Aqueducts from his boyhood. He shewed me that Signor Moraldi had not gone quite far enough, and that the real spring of the Marcia is about a mile further from Rome than the one he supposed to be so, which was a subsidiary spring, though of equally good water. At the original source the stone _specus_ was found, having been long concealed by being a foot or two under water. I saw it, and stood upon it, and had a photograph made, so that there could be no mistake, and the engineer of the company also saw it, and carried his aqueduct to that point; so that the real ancient Aqua Marcia now comes into Rome again, and is getting rapidly into general use, being much the best drinking water. The water supply of ancient Rome has long been a subject of interest, and can now be more perfectly understood than it ever could before. The series of Photographs of them are a thorough illustration of their history, such as could not have been made before that art was invented.

CONTENTS OF THE AQUEDUCTS.

PAGE

PREFACE iii

Introduction—Frontinus 1

I. AQUA APPIA.

Passages from Frontinus 3

Sources in the Lucullan fields 4

—— near the old Via Prænestina 5

The course underground 6

It entered Rome at the north-east end of the Sessorium ib.

—— passed along the Cœlian Hill ib.

Reservoir in the garden of the Villa Cœlimontana, now the Arch of Dolabella 7

It crossed the valley to the Aventine on an ancient earthwork, near the Porta Capena 8

to the Piscina Publica 9

Under the Aventine the _Specus_ is visible in a stone quarry nearly under S. Sabba ib.

Wells to descend into it ib.

The branch added by Augustus entered Rome in the garden of the Sessorium 11

—— near the Gemelli ib.

Torquatian and Pallantian gardens ib.

II. ANIO VETUS.

Passages from Frontinus 13

Sources—a branch from the river Anio ib.

Specus in the cliff of the valley 14

—— visible in the “Valley of the Arches” above Tivoli ib.

—— and in the promenade of Carciano below it 15

—— Its course underground 16

Piscinæ at the fourth, and at the second, mile from Rome, on the Via Latina ib.

Crossing of the Aqueducts at the Torre Fiscale 17

Castellum Aquæ near the Porta Furba, two miles from Rome 18

—— near the Via Appia Nova ib.

The _Specus_ faced with _Opus Reticulatum_ 19

Specus, or _spes_ (?) _vetus_, on the high banks ib.

Another branch on the bank near the Wall of Rome 20

And another branch along the Cœlian, and passing near the Port Capena, to the Aventine 21

Appendix, _Sp■_ or _Spc■_, _Spes_ (?) or _Specus_ (?) 22

—— Facsimile from MS. at Monte Cassino 26

Passages relating to the word _Specus_ 27-31

III. AQUA MARCIA.

Passages from Frontinus 32

The Piscinæ 34

Source of the Marcia ib.

Specus carried along the valley of the Anio 35

Principal source in the Acqua Serena ib.

Old _Specus_ under water, discovered in 1869 36

—— It crossed the river at S. Cosimato ib.

—— and again in the Valley of the Arches, above Tivoli, on a bridge ib.

Specus and reservoir in the Promenade of Carciano, below Tivoli ib.

Reservoir faced with Cyclopean Masonry there 37

Specus passes near Ponte di S. Antonio ib.

After reaching the City it is divided into several branches ib.

One along the Cœlian and over the Porta Capena to the Aventine 38

Another upon the old _agger_, and over the Porta Tiburtina to the Prætorian Camp ib.

Excellent qualities of the Aqua Marcia ib.

IV. TEPULA.

Sources near Grotta Ferrata 39

Specus joins the Marcia at the _Piscinæ_ 40

—— is carried into Rome on the Marcian arcade ib.

Castellum Aquæ for it near the Porta Tiburtina (S. Lorenzo) ib.

V. JULIA.

Sources on Mons Algidus (near Tusculum), Frascati, and Grotta Ferrata 41

Specus passed near the Pagus Lemonius 42

—— on an arcade of rough stone ib.

—— then through a tunnel in the valley ib.

The Nymphæum of Alexander Severus, where the Trophies of Marius were hung, was _not_ for the Aqua Julia, though usually called so. It is at too high a level for that, and was for the Claudia and Anio Novus united 43

Cippi of _the three_ Aqueducts, found in 1869, near the railway station 45

Remains of a reservoir near the Porta Chiusa, found in 1869 ib.

VI. VIRGO (AQUA DI TREVI).

Passages from Frontinus 46

Sources on the Via Collatina ib.

Specus subterranean, but easily traced by the line of respirators 47

—— It follows the old road towards the Porta Maggiore 48

—— but turns to the north and enters Rome through the Pincian Hill, under the Villa Medici ib.

—— It supplies the lower town and the fountain of Trevi ib.

—— Original termination in front of the Septa, near the Pantheon ib.

VII. ALSIETINA.

Passages from Frontinus 50

Lacus Alsietina, Lago di Martignano ib.

Aqua Paola 51

Lacus Sabatina ib.

Junction of two _specus_ at the Cariæ (Osteria Nuova) 52

Casale Bianca, additional springs ib.

In Tunnels to Rome 53

VIII. CLAUDIA. IX. ANIO NOVUS.

Passages from Frontinus 54

River Anio 56

Cascades at Valle-Pietra 57

Bridge of Communacchio ib.

Sacro Speco ib.

Monasteries of S. Benedict and S. Scholastica ib.

Subiaco ib.

Lacus—Lakes or Lochs of Nero 58

Villa Sublacensis ib.

Great dam at Piè-di-lago ib.

Bridge of S. Mauro ib.

Specus of the Anio Novus, cut in the rock of the cliff ib.

Ruins of _piscinæ_ 59

Lowest loch circular 60

Piscina Limaria, forty-two miles on the Via Sublacensis ib.

Specus of Claudia 61

Bridges at Vicovaro and in the Valley of the Arches, two miles above Tivoli ib.

Cascade at Tivoli ib.

Promenade of Carciano ib.

Bridge of S. Antonio and Ponte Lupo 62

—— near the road to Poli ib.

The _Piscinæ_ 63

Specus of the Claudia of stone, of the Anio Novus of brick over it, on a stone arcade ib.

Piscina at the Porta Furba 64

Other reservoirs ib.

The Neronian Arches ib.

Porta Maggiore, inscriptions on 65

Architect of the Claudia 66

Arcade on the Cœlian ib.

Reservoir over the Arch of Dolabella 67

Three branches from that high reservoir: 1. to the Claudium and the Colosseum; 2. to the Palatine and Capitol; 3. to the Aventine, over the Porta Capena ib.

Smaller reservoirs for subdividing 68

Rebuildings by Frontinus under Trajan ib.

Springs called _Cæruleus_ and _Curtius_ 69

The _Piscinæ_ 70

Appendix—The Nine Aqueducts of Frontinus 71

Tables of Dates, Names, Levels, Length of Channel, Supply, Distribution 73, 74

Calculations 74-79

The Curator Aquarum 80

Repairs by the Popes ib.

Popular notions erroneous 81

These stone _specus_ necessary for the main stream, and leaden pipes for distribution 82

Brass cocks and leaden pipes often stolen, as mentioned in a letter of King Theodoric ib.

X. SABATINA, TRAJANA, A.D. 110, AND PAOLA, A.D. 1540.

Lacus Sabatina, di Bracciano, or Anguillara 83

This aqueduct connected with the Alsietina (VII.) ib.

The line traced backwards by the respirators from the terminus on the Janiculum ib.

Procopius amazed at the quantity of water brought by this aqueduct in the sixth century ib.

Restorations of the Popes 84

Inscriptions of Paul V. ib.

Cascade on the Janiculum, turns the wheels of the flour-mills ib.

Specus in the wall of the garden of the Villa Pamphili-Doria 85

—— but chiefly underground, traced by the respirators ib.

XI. TRAJANA (?), HADRIANA (?), ALEXANDRINA (?).

Passage from Frontinus 86

Sources near Gabii and Labicum, now La Colonna ib.

Several springs were collected in a central reservoir, on which an inscription of Hadrian was found by E. Q. Visconti ib.

One of these springs had petrifying qualities ib.

Singular effects of the petrifying stream 87

Specus choked up with stalactite, and cascades petrified ib.

The same water used for the Aqua Felice, but the petrifying stream excluded 88

A fine arcade for miles, from the source to Cento-Celle ib.

Part of it of the first century, other part of the third. Alexandrina (?) ib.

Aqueduct of Hadrian mentioned by Spartianus, but not in the Regionary Catalogue 89

Branch from the great aqueducts to the Mausoleum of S. Helena (Torre Pignattara) and to the Villa of the Gordiani (Torre de' Scavi) 90

—— not connected with this aqueduct ib.

—— but also has _piscinæ_ of the first and third centuries ib.

Branch of Trajan to the Aventine from the Cœlian ib.

XII. AURELIA, A.D. 185. XIII. SEVERIANA, A.D. 190.

The Aurelia made by Marcus Aurelius 92

—— to convey water to the Villa de Quintilii ib.

—— continued by Commodus and Septimius Severus to their _thermæ_ in Regio I. ib.

Remains of _piscinæ_ outside of the Porta Latina ib.

Remains of the _thermæ_ inside of that gate ib.

Sources on the hill of Marino 93

Specus partly underground, part on arcade at the Torre di Mezza, Via di Albano ib.

Large reservoir at the Villa de Quintilii ib.

Others on the Via Appia, between that Villa and Rome ib.

—— at the Circus of Romulus ib.

—— at S. Urbano ib.

—— at the Nymphæum in the valley of the Caffarella (miscalled the Fountain of Egeria) ib.

Specus visible in the cliff of that valley, near the Dio Ridicolo 94

Remains of the _thermæ_ in the Monte d'Oro ib.

XIV. ANTONINIANA, A.D. 215.

This aqueduct enters Rome at the south-east corner 95

—— passes over the arch of Drusus ib.

—— along the inner side of the great bank on which the Wall of Aurelian is built ib.

—— to the _piscina_ of the Thermæ of the Antonines or of Caracalla ib.

Fine _piscina_ and _castellum_ on the edge of the hill overlooking the valley of the Caffarella ib.

Remains of others on the Via Latina 96

—— and one near the Porta Furba, at two miles from Rome, at the foot of the great aqueduct ib.

A branch of the Anio Vetus (?) ib.

XV. ALEXANDRINA.

This aqueduct mentioned by Lampridius 97

—— Made to bring water to the Thermæ of Alexander Severus, near the Pantheon ib.

—— Probably a branch from the great aqueducts near the Porta Maggiore ib.

An inscription found near that point ib.

Remains of arcade of this period between that gate and the Minerva Medica 98

Nymphæum of Alexander Severus, where the Trophies of Marius were hung 99

Nymphæum, a hall of the Thermæ for women; Pantheum, a similar hall for men ib.

Wall of Aurelian built against this tall arcade ib.

XVI. ALGENTIANA.

This aqueduct made to supply water to the Thermæ of Diocletian 100

Remains of a large _piscina_ were found on the site of the railway station ib.

The water is said to have been brought by a branch from the Marcia at the Porta di S. Lorenzo ib.

Others say it came from Mons Algidus, near Tusculum, and was brought underground, with reservoirs on the tops of hills in the Campagna, supplied by syphons ib.

XVII. AQUA CRABRA AND MARRANA.

These streams united are brought into Rome in the bed of the River Almo 101

Sources of the Aqua Crabra, near Rocca di Papa ib.

Those of the Marrana near Marino ib.

The two united at the foot of the hill of Marino 102

Piscina in the valley under Marino ib.

Specus traced in the same valley near the quarries of _peperino_ or _lapis Albanus_ ib.

—— passes under the sources of the Aqua Julia ib.

The two streams united near a bridge on the road to Grotta Ferrata, ten miles from Rome ib.

Part of the united water runs into the river Anio ib.

Another part is brought through the tunnel of the Aqua Julia (V.) ib.

—— then in a cutting to the bed of the small river Almo ib.

It is carried alternately in that deep bed when the ground is high, and in a bank of clay when the ground is low 103

The stream is divided at a loch between Roma Vecchia and the Torre Fiscale ib.

One branch follows the line of the great aqueducts towards Rome, in the bed of the Almo ib.

It enters Rome in that bed, under the bridge on which the Porta Metronia stands ib.

It then passes the Garden of Crassipes, now the Orto Botanico 104

—— turning to the north, under the Aventine, to the Piscina Publica ib.

—— passes through the Circus Maximus, and under several mills ib.

—— to the mouth of the river Almo in the Tiber, through an opening left for it in the Pulchrum Littus ib.

This Aqueduct was made under Pope Calixtus II. in A.D. 1124 ib.

Another branch of it is carried by the side of the other branch of the river Almo, in the valley of the Caffarella, and the other _specus_, which is open on the top, has lochs in it there 105

XVIII. AQUA FELICE, A.D. 1587.

So called after Pope Sixtus V. (Felice Peretti) 106

Source under La Colonna ib.

Reservoir made under Gregory XIII., A.D. 1572-1585 ib.

The arcade and _specus_ were made under Sixtus V., but other reservoirs were not completed until Urban VIII., A.D. 1623-44 ib.

The _fistula Urbana_ of marble ib.

The piers and foundation of the old arcade used ib.

The _specus_ enters Rome near the Porta Maggiore 107

The water is then divided into different branches ib.

Junction of this arcade with the old one of the Claudia 108

From the Porta Maggiore the main line is carried upon the same high bank as the old Aqueducts ib.

It turns at the Porta di S. Lorenzo 109

—— and is carried on an arcade to the great _agger_ on the Viminal, and to the fountain of the Termini, called that of Moses ib.

SUMMARY.

Frontinus mentions _nine_ Aqueducts 110

The Regionary Catalogue of the fourth century enumerates _nineteen_ Aquæ in Rome ib.

Some of these were natural watercourses 111

Procopius in the sixth century mentions _fourteen_ only 112

LEVELS OF THE AQUEDUCTS 113

AQUEDUCTS.—LIST OF PLATES.

PHOTO-ENGRAVINGS.

PLATE

I. Source of the Aqua Appia, in a very ancient Stone-quarry of the time of the Kings, on the bank of the river Anio.

II. Source of another Spring of the Aqua Appia in another ancient Stone-quarry, (near to the former).

III. 1. THE AQUEDUCTS ABOVE SUBIACO.

2. —— River Anio, the Upper Lochs.

—— —— the third Loch and the Bridge over it.

IV. 1. —— Anio Novus, the third Loch.

2. —— —— The Specus.

V. —— Anio Novus—a Castellum Aquæ, and Line of the Specus cut in the cliff.

VI. The Claudia, Anio Vetus, and Novus, and Marcia, in the Valley of the Arches below Subiaco and above Tivoli.

VII. Two other Views of the Ruins of the Arcades of the Claudia and Anio Novus (in the Valley of the Arches above Tivoli).

VIII. Aqueducts at Tivoli—Cascades of the Anio, with the Round Temple of the Sibyl at the top.

IX. Aqueducts below Tivoli—The Marcia—a great Castellum Aquæ on the Via di Carciano, B.C. 145.

X. Aqueducts below Tivoli—Aqua Marcia—Reservoir, or Castellum Aquæ. Views of the two chambers.

XI. Aqueducts below Tivoli—1. Anio Novus—Castellum. 2. Marcia—Castellum rebuilt by Trajan.

XII. The Claudia and Anio Novus in the Campagna of Rome, near Roma Vecchia, over the fine arcade, four miles from Rome.

XIII. The Claudia and Anio Novus passing over the Marcia, Tepula, and Julia, at the Tor Fiscale, and view near the Porta Furba.

XIV. 1. The Marcia on the bank within the wall of Aurelian, at the Porta Tiburtina.

2. Claudia and Anio Novus at the angle of the Sessorium.

XV. Aqueducts at the Porta Maggiore—

1. Marcia, Tepula, and Julia, entering Rome, passing through the Wall.

2. Marcia, &c., within the Wall.

XVI. 1. Claudia and Anio Novus over the Porta Maggiore.

2. Anio Novus on the Cœlian, over the arch of Dolabella.

XVII. 1. Arches of Nero within the Porta Maggiore, crossing the great inner _fosse_ of the Sessorium on a double arcade.

2. Aqua Marcia within the Porta Maggiore, as shewn in an excavation in 1871.

XVIII. 1. The Claudia and Anio Novus, in the North Wall of the Gardens of the Sessorium, now of S. Croce.

2. Nymphæum of Alexander Severus, where the trophies of Marius were hung.

XIX. Great Reservoir on the Arches of Nero over the Arch of Dolabella, on the Cœlian.

PLANS AND DIAGRAMS.

PLATE

I. Plan of the Sources of the Appia and Virgo, in the meadows of Lucullus, on the bank of the river Anio.

II. The Appia at the Porta Capena, the specus passing through one of the towers of the Porta Capena, now a gardener's cottage.

III. The Appia under S. Sabba. The specus in an old stone quarry on the Pseudo-Aventine.

IV. Mouth of the Appia under the Aventine, and at the Porta Trigemina, now in a Cave under S. Alexio and the Priorato.

V. Aqua Appia—Reservoir in Garden of the Sessorium, now of S. Croce, called the Thermæ of S. Helena.

VI. Anio Vetus.—Reservoir near the Porta Furba.

VII. Loch in the Aqua Julia, near the Imperial Villa, called the Sette Bassi.

VIII. Aqueducts and River Almo, near the Porta Furba.

IX. The Seven Aqueducts at the Tor Fiscale. Plan and Section.

X. Piscina of the Anio Novus, entering Rome through a tower in the wall of Aurelian in the garden of the Sessorium.

XI. The Aqueducts at the Porta Maggiore and the Porta Tiburtina. Plan and Section.

XII. Nymphæum, where the Trophies of Marius were hung. Plan and Section.

XIII. River Almo—Division into two Branches, now a Loch of the Marrana.

XIV. River Almo, now the Marrana.—Entrance into Rome under the Porta Metronia.

XV. River Almo—Mouth in the Pulchrum Littus. View.

XVI. —— Plan.

XVII. Sources of the Aqua Appia, near the bank of the river Anio, in a very ancient stone quarry.

XVIII. Aqua Appia, or Appian Aqueduct, crossing the valley from the Cœlian to the Aventine upon the short Agger of Servius Tullius, and over the Porta Capena.

XIX. Plan and Sections of the Aqueducts in a Cave in the Aventine, under S. Sabba, with the Excavations made in 1875 and 1876.

XX. Plan and Section of the Aqueducts, from the great Reservoirs on the Cœlian Hill, near the Arch of Dolabella and the Claudium, to the Colosseum, and to the Drain under the road from the Arch of Constantine to the Clivus Scauri.

XXI. Sections of the Specus or Conduits of fifteen different Aqueducts.

Plan of the Aqueducts on parts of the Cœlian and the Esquiline Hills, from the great Reservoirs and Piscinæ called Sette Sale, on the Esquiline, to the Colosseum; and the Three Branches from the great Reservoir on the Cœlian, and over the Arch of Dolabella,

and the Piazza della Navicella, to the Aventine, the Palatine, and the Colosseum.

Map of the Aqueducts on the Eastern side of Rome, from their Sources above Subiaco, and on the bank of the river Anio, to Rome, and their mouths in the Tiber.

—— Western side of Rome, from their Sources in the lakes on the hills, called Alseatina and Sabatina, or Anguillara.

CHAPTER IV. PART I.

THE AQUEDUCTS.

In treating of the Aqueducts we have a trustworthy guide in a writer who flourished in the time of the Emperors Nerva and Trajan, namely, SEXTUS JULIUS FRONTINUS[2]. While he informs us of what improvements he made during the time he had the charge of these important public works, he also gives in his treatise a historical account of the several changes which had been from time to time made in the means of supply of water to the Imperial City, which kept pace with the growing wealth and population of Rome. When he died they had probably reached perfection, and were justly the admiration and surprise of all travellers[3].

His treatise is well worth examination, not only from an archæological point of view, but as suggesting also many curious enquiries as to the engineering abilities which the Romans possessed, compared with those exhibited at the present day. In elucidating, however, the architectural antiquities of the city of Rome, it will be necessary, as far as possible, to limit the extracts from his treatise _De Aquæductibus_, to those portions which refer either directly to existing remains, or which indirectly explain them, by pointing out the principle on which the several Roman aqueducts seem to have succeeded each other.

Frontinus tells us in his fourth chapter, that for 441 years after the building of the city, or until B.C. 312, the people were content with the water which they could draw from the Tiber, or from wells[4] or from springs, of some of which the memory was in his time still held sacred and honoured, for they were thought to afford health to the sick[5].

Passing to his own time, he says, “there now flow into the city:”—

I. Aqua Appia. II. Anio Vetus. III. Aqua Marcia. IV. ” Tepula. V. ” Julia. VI. Aqua Virgo. VII. ” Alsietina (which is also called Augusta[6]). VIII. ” Claudia. IX. Anio Novus.

Frontinus describes the above nine aqueducts in order, giving details as to the source of the water in each, the quantity, and the distribution. Such extracts as are calculated to throw light upon the existing remains, are given in the course of the following remarks. Seven other Aqueducts were added after the time of Frontinus at different periods, of which an account will also be found in the second part of this Chapter.

I. THE AQUA APPIA (A.U.C. 441, B.C. 312).

“The _Aqua Appia_ was brought into Rome by the censor Appius Claudius Crassus, afterwards called _Cæcus_ (the blind), who also caused the Via Appia to be constructed from the Porta Capena to the city of Capua[7].”

“The Appian stream rises in the Lucullan fields on the Via Prænestina, between the seventh and eighth milestone, and about 780 paces (or about ¾ of a mile) off on the left-hand side. The channel from its source to the ‘_Salinæ_,’ which is a spot near the Porta Trigemina, measures 11 miles, 190 paces (about 300 yards) in length. For 11 miles, 130 paces, (about 200 yards,) the channel runs underground, and for 60 paces (about 100 yards) it is carried above ground on a substructure and arcade (in the part) nearest to the Porta Capena[8]. At the ‘_Spes (Specus) Vetus_,’ (the old _specus_ or conduit,) on the confines of the Torquatian and Pallantian gardens, a branch called the _Augustan_ was added to it by Augustus as supplementary, whence it received the name of ‘Gemelli[9]’....”

“The distribution of the Appian water begins at the bottom of the _Clivus Publicii_ at the Porta Trigemina[10]; the stream having passed beneath the Cœlian and Aventine Hills.”

“... The measure at the head of this could not be obtained because it consists of two channels. At the Gemelli, however, which is under[11] the _Spem (Specum) Veterem_, (the old conduit,) where it joined with the Augustan branch, I found the height or depth of the water to be 5 ft., the width 1 ft. 9 in., which makes the area 8 ft. 9 in.: ... it should be noticed that the water in many parts of the City was observed to be lost, that is, by trickling away. Moreover we found some of it intercepted by illegal pipes within the City;

without the City, owing to the pressure, that which was underground (at the head 50 ft.), received no injury[12].”

The Lucullan fields, in which are the sources of the Aqua Appia, are nearly due east from Rome, on the bank of the river Anio, at about six miles from the present gates of Rome, and three quarters of a mile off the Via Collatina, now a cart-road. This is the old Via Prænestina, which went through Collatia, now called Lunghezza, about two miles higher up the river Anio, at the point where the smaller river Osa falls into it. In this part the old paved road remains for some distance in use, both before and after the entrance to Collatia, and was the more direct road; the present carriage-road, now called Prænestina, was the Via Gabina, and went through or near to Gabii, but was not so direct a line to Præneste or Palestrina as the one through Collatia. The old road passes close in front of the ancient stone quarries, on the bank of the Anio, in which one of the springs or reservoirs of the Aqua Appia is situated; the pavement of it remains, and is now used as a foot-path only.

There are several springs or sources for this aqueduct, and also several ponds to collect the rain-water, made in the clay, the water from all of which was collected into a central reservoir cut in the rock, with a large well over it. There are also seventeen wells visible in two lines, eight in one and nine in the other, converging and meeting in the central reservoir. The soil is clay upon stone. The _specus_ is here a large tunnel cut in the rock, and the wells descend into it. They may be distinguished from above by the bramble-bushes which grow over and cover each of the openings, and do not grow on the other part of the field; each well is also protected by a wooden rail, to hinder cattle from falling into it. The water still runs through in some parts. Near to this reservoir is a tomb of very early character, similar to what are usually called Etruscan[13] tombs, cut out of the rock.

As the length of its course was rather more than eleven miles, while the distance by the Via Prænestina direct was only between seven and eight, it is clear that it did not follow that road. It was carried to the south towards the Via Labicana by a winding course, according to the levels of the ground. The Aqua Virgo, whose source is in the same Lucullan fields as the Appia, is carried to the north by another winding course of a greater length, to supply the northern parts of the city.

The course of _the old Via Prænestina_[14] has undergone but little change, and the 7th milestone is soon measured. A little beyond it, and 780 paces off on the left of the road (i.e. on the northern side), we are brought to a point[15] where the sources of the Aqua Appia are still to be seen in caves formed by ancient stone quarries, near a tenement called _La Rustica_. One cave is of a triple form, with three springs, and the soil above the stone is much mixed with clay. These three springs meet at the mouth of the cave in one stream, which runs in the old _specus_ cut in the rock, but open at the top, and having the appearance of a mere country ditch, half hid by the grass and weeds in the winter, and in the summer months entirely concealed by them. This _specus_ runs across a low meadow for about a quarter of a mile. It crosses the line of the Aqua Virgo, the respirators of which cross this meadow in an opposite direction; the sources of the Virgo are about a mile further from Rome, on the same road. It then enters the rock again in a tunnel, and at this point is the first _castellum_ or reservoir, with a large circular well cut out of the rock, which forms the vault over it. There are the grooves for sluices at each end of the reservoir, and an opening has been made into the tunnel a little beyond this reservoir. The course of the aqueduct is then in a tunnel entirely underground, in the direction of a series of ancient caves, through which, or by which, it must pass, but being underground it cannot be seen. These caves are evidently an ancient stone quarry, but of later character than the one first mentioned. In the earliest one, at the source, the stone has been split off the rock, not cut; in the other caves, the stone has been well cut, and of these many are to be seen, the openings being large square apertures like doorways, but side by side in the face of the scarped cliff, not following each other: a practice common in quarrying, where the circumstances require it, down to the present day. Between the chambers are massive square or oblong piers, left to support the vault and the earth above. At the bottom of one of these chambers is water running from another spring, and the shepherds state that there is an opening from it to the _specus_ of the aqueduct; but as the bottom is filled up to the depth of several feet with broken stone, it cannot be seen. Some of the chambers of this ancient quarry have been used as a burying-place, probably for the neighbouring town of Collatia. The graves are cut out in the side of the walls, like the _loculi_, and there are also chambers like the _cubicula_ of a catacomb. The tombs of this necropolis of Collatia are very ancient, perhaps anterior to the Kings of Rome, and certainly not posterior to the Republic. This stone has been cut out in large square or oblong blocks, such as are usual in work of the time of the Kings; it is probable that Appius Claudius made use of a quarry which he found, and that the ground was not excavated for the purpose of the aqueduct only.

From this point the course was entirely underground, therefore no traces are visible without some difficulty. Incidentally, as we have seen, Frontinus notes, that at the head the water ran as much as fifty feet below the surface, and was thus protected from being fraudulently diverted. It could not have taken a very direct line, as the levels of the crossing valleys must have necessitated here and there a circuitous course; and moreover this is clearly implied by Frontinus, who says that the total length from the source to the “Salinæ” was more than eleven miles, while the distance in a direct line is less than nine miles. As it had no _piscina_[16], it

flowed on in an uninterrupted course to the spot where it was distributed for the public service.

One branch seems to have entered Rome under the line of the Claudian arcade, near the Porta Maggiore[17], and its course within the city is not difficult to follow, since for certain purposes access has been made in more than one place into the old _specus_, part of which is used to carry the lead pipes of the Aqua Felice to the Hospital of the Lateran and other places. From the surface where one of the shafts is situated to the bottom of the channel, is a depth of twenty-five feet. No water runs along it at present, except in the metal pipes from the Aqua Felice, belonging to the modern system.

The direction of this channel, after it enters Rome, happens to be easily seen above, as it is marked throughout its course, from the eastern end of the Cœlian to the Arch of Dolabella, by the fine arches of the Neronian branch from the Claudian Aqueduct erected almost over it. It is very probable that one of the laws (referred to by Frontinus as having been in existence long before his time) respecting aqueducts was in force from the commencement, namely, that there should be no buildings of any kind within ten feet on either side of the aqueducts; thus an open space was probably existing at the time when Nero wished to carry water to his magnificent reservoir at the north-western end of the Cœlian, and of this he availed himself in rearing the splendid arcade which is called by his name. It will be remarked, however, that the brick buttresses actually came down to the flat roof of the original _specus_ of the Appian. The top of that _specus_ was raised to a greater height by the engineers of Sixtus V., and in this enlargement the underground supports of the Neronian arches are cut through to give headway to the _aquarii_ passing along the channel. They have however to stoop their heads as they pass under each buttress.

The old tunnel _specus_ was discovered in the time of Sixtus V., (Felice Peretti), filled up by clay deposit to the depth of three feet, or half the height of the _specus_, as in other places, and the builders found it easier to raise it, for the _aquarii_ to go along it, than to clear it out. They therefore knocked away the flat tile-covering of the time of Nero, and raised a vault of rubble-stone three feet higher.

From the great subterranean reservoir, still in use for the water of a spring, near the Arch of Dolabella, to the edge of the western cliff of the Cœlian is but a short distance, and here the _specus_ seems to run in a bank dividing the vineyard or garden of the Villa Mattei from that of the monks of S. Gregory, on which a wall has been built. At this point subsequent alterations, and especially those under the Emperors Nerva and Trajan, have buried to a great depth the actual remains of the original aqueduct; but this later work occupies the same line, and must be described. We first come to a large _piscina_ or filtering-place on the cliff of the Cœlian, immediately above the Porta Capena. This _piscina_ is divided into two parts, one above the other; but both are below the top of the cliff, and are faced with brick and reticulated work of the time of Trajan. There are remains of two _specus_ running along against the face of the cliff; of the upper one the lower part, or pavement, of _Opus Signinum_, only remains, and this runs down in a sloping direction from the upper reservoir to a lower one, a little to the south of it, which is very extensive. This lower reservoir consists of several parallel chambers, through which, or rather in front of which, another _specus_ runs at a lower level; this appears to be horizontal. This _specus_ goes on in the direction of the ruins of a building of various periods, possibly the remains of the Ædes Camenarum, and passes then to the south in the direction of the Thermæ of Severus and Commodus.

Another branch was evidently afterwards made from the upper reservoir going towards the north for a very short distance, merely for one of the usual angles; then, turning again to the west, in the valley below, there is another large _castellum aquæ_, or reservoir of five chambers, all as usual oblong and side by side. This is on lower ground, and is built upon the wall of Servius Tullius, where it crosses the valley; the upper part of this reservoir has been made into a house for the gardener. The underground part of the chamber nearest to the Cœlian is built of the large square blocks of tufa usual in the time of the Kings, and belongs to the fortifications of the Porta Capena, over the Via Appia, which here passed close under the Cœlian; the other chambers appear, from the bricks, to be of the time of Trajan. From this point to the Piscina Publica, the line of tall brick piers of Trajan can be distinctly traced by the existing remains, passing across to the other side of the road and of the stream here close to it[18]. The ruins of the Piscina Publica, as rebuilt by Trajan, remain visible under the corner of the Pseudo-Aventine, near S. Balbina, and from this the water was again distributed in different branches. At this point, let it be observed, and only at this point, is the valley which divides the Cœlian from the Aventine sufficiently narrow to admit of agreement with the direct and clear assertion of Frontinus, that here alone, throughout the whole course, was it carried on a substructure and on arches for a distance of one hundred yards.

Although there are no remains of the _specus_ now visible at this spot, because the gate has been destroyed, there can be little doubt that the channel for the water was carried _over_ the southern gate of _the city_ according to its extent at that time. This gate was called the Porta Capena; and as the Appian aqueduct was allowed to fall into decay, it gave rise to the descriptions both of Martial and Juvenal, who describe it as wet or moist[19].

The excavations made in 1868 and 1869 under the direction of Mr. Parker, with the help of the British Archæological Society of Rome and the Roman Exploration Fund, have clearly shewn the _specus_ of the Aqua Appia and those of two other aqueducts carried upon the _agger_ of Servius Tullius across the valley from the Cœlian to the Aventine, with branches to the left running into the subterranean chambers of the Piscina Publica. These underground chambers are of the time of the Republic, the walls are built of rubble stone as usual at that period, and there are small openings through these walls for the circulation of the water, although the upper part has been rebuilt in the time of Trajan, as the remains of the wall are faced with the brickwork usual in his time. The lowest _specus_ is cut out of tufa rock _under_ the wall of Servius Tullius, which is built of the usual large blocks of tufa.

The principal branch went underground to the cave reservoir at its mouth, on the level of the quay of the Marmorata between that and the Salaria, just outside of the old Porta Trigemina; the old _agger_ in which that gate was situated still forms the southern or lower boundary of the wharf of the Salaria. Part of the course of this earliest _specus_, that of the Appia, can be traced and seen in a subterranean stone quarry nearly under S. Sabba. The _specus_ is six feet high and two feet wide, and it is filled up to nearly half its height by solid clay, evidently the deposit left by the water. The old _specus_, long after it had been out of use, seems to have been employed by the quarrymen: as it was a tunnel in the tufa rock just high and wide enough for a man to walk in, by cutting away one side they made it wide enough for a horse and cart to carry the stone, and they raised the vault as high as was convenient for the purpose of making an entrance into the quarry. The series of wells descending into the old _specus_ from the gardens above remain at intervals, with notches for steps cut in the rock to enable a man to go up and down when required. The course of the _specus_ is cut off by the road to the Porta Ostiensis, but probably that road was originally carried over it[20] at the crossing; it then passed through another large subterranean quarry nearly under S. Prisca, to the cave reservoir at its mouth[21].

Before arriving at the two large reservoirs just outside of the garden of the Sessorium, now Sante Croce, the _specus_ of the Appia must have passed by another smaller reservoir at the same low level, near the ruins of the apse of a hall, miscalled the temple of Venus and Cupid. This seems likely to have been the point at which the branch _specus_, coming from the north, entered Rome, and it was then carried on to the two large reservoirs outside this garden, supposed to have been the _Gemelli_[22].

Below the “Salinæ” or salt warehouses on the bank of the Tiber, and near the “Porta Trigemina,” the water was “distributed.” This was also close under the Clivus Publicii, or the slanting zig-zag road leading up from the wharf to the top of the hill.

So far the general course can be traced; but the exact point of entrance into Rome could not be fixed without excavations, which have not as yet been made. There are, however, some _data_ given by Frontinus which should not be overlooked, as they bear incidentally upon the course of some other of the aqueducts.

First, it should be remarked, that the water of the Appia was augmented by an additional stream. This was not accomplished till the time of Augustus. The source of this latter[23] was on the same side of the Via Prænestina, but a little nearer to Rome (near the sixth milestone) we are told, and its course was, like the main stream, entirely underground. It was more direct, as its length was less than six miles and a-half, while the original stream, by its windings, required about eleven miles to complete the same distance[24].

It joined, however, the Appia _at the “Spes (Specus) Vetus,”_ and at the Gemelli[25], which was _under (infra) the “Old Specus,”_ it could be measured. This is an important landmark; it is well at once to observe that the usual interpretation of the passage as referring to a “Temple of Spes,” and the statement that a temple occupied the site of some ruins which are marked thus in a few maps, (in most, _Templum Veneris et Cupidinis_) does not seem to fit the circumstances. It is proposed to read in both these two instances “Specus Vetus.” The expression occurs, altogether, five times in Frontinus, and it will be most satisfactory therefore to consider the passages together, which will be done more conveniently in connection with the next aqueduct described.

The Torquatian and Plautian, or Pallantian gardens, seem by the context to have occupied a spot on either side of the point of junction of the two streams. The Torquatian gardens are not mentioned elsewhere, and with respect to the Plautian[26] (which is only conjectural, and has the authority of neither of the early MSS.), it has been suggested to read _Pallantian_, which gardens are mentioned twice elsewhere by Frontinus in connection with the Specus Vetus, besides once in such a way as to imply the same[27].

The Torquatian gardens probably occupied the space between the outer wall and the modern “Via di Porta Maggiore,” and were probably those of Titus Manlius Torquatus, a member of an important patrician family; Livy mentions at least three generations of that name. This ground shews numerous remains of aqueducts and reservoirs, and here also is the fine building of the third century called the Minerva Medica, which was probably the _nymphæum_ of some _thermæ_ of that period[28]. The Pallantian gardens is

a natural name for those belonging to the Sessorium, or the Sessorian fortified Camp and Palace[29], and occupied the low ground near it. They would therefore be to the south of, but adjoining to, the Torquatian gardens.

II. THE ANIO VETUS (B.C. 272).

“Forty years after the Appian aqueduct had been completed, and in the year A.U.C. 481 (B.C. 272), Marcus Curius Dentatus, who bore the office of censor with Lucius Papirius Cursor, contracted to bring into the city the water of the Anio, which is now called the Anio Vetus, from the spoils taken of Pyrrhus[30].

“The Anio Vetus takes its rise beyond Tibur (now called Tivoli), outside the gate, at the twentieth milestone, where it parts with some of its water for the use of Tibur. Its course has in length, in consequence of the difficulties caused by the levels, 43 miles. Of this for 42 miles and 779 paces, the stream is underground, and for 221 paces (about 350 yards) on a substructure above ground.

“Near the fourth milestone within the new road (_infra novum_) the Anio Vetus crosses between the arches from the Via Latina into the Via Lavicana, and has (there?) a _reservoir_ (or _piscina_). Thence just within the second milestone it gives a part of its water into the _specus_, which is called the Octavian, and this comes in the direction of the New Road to the Asinian Gardens, whence it is distributed through that neighbourhood; but its direct channel, following the _specus_ (or conduit) coming within the Porta Esquilina, _along_ the _Spes (Specus?) Vetus_, is drawn off for distribution in the city, through the high channels[31].

“It held the sixth place in height, but would have been sufficient for even the higher parts of the city, if it had been carried across the valleys and the low ground, where requisite, upon substructure, arches, and buttresses[32].”

Passing on to the second aqueduct, namely, the stream taken from the River ANIO (and which was called the ANIO VETUS to distinguish it from a later diversion from the same river), we find that Frontinus is also very distinct in many of his details; a few only he leaves to conjecture.

The point where a branch was taken from the river Anio can be traced[33]. There was a reservoir by the side of the river, of which some ruins remain; but it was nearly destroyed a few years since by some peasants in their ignorant and too eager search after hidden treasure which they expected to find there. The _specus_ is cut in the rock as a tunnel in the cliff of the valley of the Anio, just below the level of the road; it follows the line of the cliff, of the river, and of the road: for they are all the same, the only opening through the rocky mountains of limestone in this part, obviously made by the river itself. It follows this line as far as the valley called the “Valle degli Arci,” or of the Arches, where three later aqueducts cross the river on arcades about two miles above Tivoli. At this point several aqueducts are visible crossing the valley on arcades, each on a separate arcade, not three on one arcade and two on another, as near Rome. The one nearest to Tivoli is the Marcian, and at the foot of one of the piers of the arch, which here crosses the road, the _specus_ of the Anio Vetus is visible, partly underground, but the upper part above ground, on the right-hand side of the road in going from Tivoli. It then is carried in a tunnel through the hill, but appears again on the other side with a large reservoir, and runs gradually downwards in a winding course round part of the hill.

It is not easy to distinguish to which of the aqueducts belongs any one of the numerous reservoirs, the ruins of which are conspicuous objects on the roads up to Tivoli on the other side towards Rome, especially along both sides of that called the “Promenade of Carciano,” for the distance of about three miles from Tivoli. The _specus_ and reservoir of the Anio Novus are on a natural terrace above that road, and the Marcia below it; these have passed through Tivoli, winding round that end of the hill. The Claudia passed upon a great arcade the valley of the Arci, and another valley in the direction of Gerocomio. The Anio Vetus was carried in a tunnel through the hill, and appears on the other side near Tivoli, at a considerably lower level than the others. The road passes across the _specus_, and is made upon the surface of the vault, which is visible about four miles and a-half from Tivoli. A little further on there are two large reservoirs belonging to it, near a modern villa called Gerocomio, built by the Cardinal Santacroce in the year 1579, now a farm-house only, but on the site of an ancient villa, of which some remains are built into the walls. One of these reservoirs or _piscinæ_ (?) appears to be unaltered, the buttresses remain and apparently the vault; but it is covered with herbage and shrubs, which conceal it. The other has been turned into a cottage or an out-house of the villa, and this is of later date than the other. The Anio Vetus, the Marcian, the Claudian, and the Anio Novus, all have to be conveyed down this lofty hill from the high ground on which the remains above mentioned are situated, to the valley below. The river Anio itself rushes straight down the celebrated cascades by a fall of about a hundred feet; but the channels of the aqueducts follow a winding course, which allowed of the descent towards Rome being very gradual.

This road or promenade of Carciano is rather high on the side of the hill above the villa of Hadrian, looking towards Rome. The dome of S. Peter's is distinctly visible from it. The road is on a ledge on the side of the cliff, and the aqueducts run along the steep side of the hill or cliff, until they come to the valley of a small stream winding down to the Anio; along the cliff of this they are then carried. The Anio Vetus being at a considerably lower level, is more difficult to trace than the others; but it seems clear that after the later aqueducts had arrived at the point where the Anio Vetus emerges from the hill, they all followed the same line, winding along with the small stream, and their _specus_ or channels cut in the cliffs as far as they could be made available. The Anio Vetus has been discovered at the left hand of the modern road to Rome, and to the right of the promenade of Carciano. It passed, upon a lofty bridge called the Ponte di S. Antonio, over a torrent, with the Marcia. Afterwards upon another bridge called Ponte delle Mole di S. Giovanni, and over the Ponte Lupo it went with the others. Near Gallicano (or the ancient Pedum) are two _cippi_ of Augustus in two wells of his _specus_; one is in the country called Le Sette, and another at Obrego[34] dell' Ermito. The others have all been followed, and an account of them will be found under their respective heads.

In order to avoid the many small valleys occupied by streams which run parallel to each other from the hilly ground on the south, down to the river Anio on the north, (the general course of which river is west and east,) the course was kept along the higher ground, and in fact wound round the heads of those valleys in order to retain a level, gradually becoming more and more depressed, till, by the time it reached Rome, the base of the _specus_ (according to the computation of Piranesi), was 55 ft. above that of the Appian[35]. The whole course is underground, as has been said, except for 221 paces (about 360 yards); for this short distance it was carried on a substructure above ground. It is reasonable to suppose that this exception to the subterranean course was, as in the case of the Appian, within the present boundary of the city.

Before it reached Rome, two circumstances have especially to be noted. Just within the fourth milestone we are told it had a reservoir and _piscina_ or filtering-place, and at the second milestone it parted[36] with some of its water, which was conveyed to Rome in a separate channel.

This fourth milestone was clearly on the Via Latina, as Frontinus in the previous paragraph had referred to some _piscinæ_ at the seventh milestone on the same road; and it appears, although the sentence is exceedingly corrupt, that the course of the Aqueduct left the Via Latina at this point, and crossed towards the Via Labicana "amongst the arches[37]" at the fourth milestone. The _specus_ is here visible, and appears to be perfect; it is very near to the Torre Fiscale[38], between that and the Osteria, called the Tavolato (which itself appears to be made out of another, but a later, reservoir belonging to the aqueducts, as many of the houses in the Campagna have been). The vault of the old _castellum aquæ_ or _piscina_ is now covered with turf, but the side of it forms a sort of cliff like the edge of a quarry.

This place, where the Anio Vetus leaves the Via Latina, is near the great junction and crossing of the aqueducts, over which the tall medieval tower called the Torre Fiscale has been built. Here six aqueducts meet and cross each other. The Marcian arcade, with three of these, makes one of its many angles, and the lofty Claudian arcade, with two more, is carried over it. The expression that it passed amongst the arches is a very natural one, to any person who knows the locality, as there are many arches at this point. It then goes on to another angle and crossing of the great aqueducts, where there is a gate called Porta Furba, about two miles and a-half from the Porta Maggiore. There is a _castellum aquæ_ of the time of Nero, with an ancient _piscina_ under it, and a fountain of Sixtus V. by the side of it. At the second milestone it parted with some of its water into the _specus_ called the _Octavian_, which enters Rome at the Asinian gardens, following the direction of the new road.

By referring to the maps it will be seen that the original line of the Via Latina united with the Via Appia within the outer wall and before reaching the old southern entrance of the city (the Porta Capena); but, in joining this latter road (the most convenient course to pursue in the then state of the fortifications), the Via Latina swerved rapidly to the south-west. Had it been continued in a direct line, it would have reached the Cœlian Hill, near the Porta Asinaria, as the Via Appia Nova still does, following the line of the old Via Asinaria.

At this second milestone also is another _castellum aquæ_[39], mentioned by Frontinus as two miles from Rome. This is near the Porta Furba; it is entirely buried, but the vault of it is not many feet underground. In the spring of 1871, some excavations were made under my direction in a large vineyard hard by, and another subterranean reservoir was found near the road to Tusculum and Frascati, with a _specus_ cut in the rock going in the direction of that road, and apparently passing under it, on the line of a cross-way to the Via Appia Nova, a short distance only. On the other side of that is the "Albergo dei Spiriti," near the junction with the Via Latina; and, in the garden at the back of that house, a _specus_ was found in a stone quarry, the vault of which had fallen in and brought the _specus_ to view. It seems to have passed underground along the southern side of that ancient Via for a short

distance, and then crossed it to a _piscina_, of which there are remains at the foot of the bank on which the road runs in that part. It then goes along the edge of some higher ground, and for a short distance underground again towards a by-lane (_diverticulum_), parallel to the Via Latina; remains of a brick arcade can be seen on the bank of that lane, which is a deep foss-way, and goes on to Rome about a mile distant. It is cut by the railway before it arrives at the wall of Rome. It then passes through that wall and underground again as far as the arch of Drusus, over which it passes; and thence on an arcade, part of which only remains, to the great _piscinæ_ at the back of the _thermæ_ of Caracalla[40].

The Via Appia Nova was probably made in the time of Frontinus, and is the road which he calls Via Nova. The part nearest to Rome was previously called the Via Asinaria, and extended from the Porta Asinaria to the junction with the Via Latina, at three miles from Rome, which name was then dropped. The new road continues parallel to the Via Appia Antiqua as far as the eleventh milestone, and there forms a junction with it. Both of these roads are now open. The railway to Capua and Naples passes near to this point of junction. The short Via Lateranensis, going out of the Porta Lateranensis (excavated in 1868), ran into the Via Asinaria, and so joined the Via Appia Nova, which has tombs of the first century along the line, and none of any other period. Those which were of stone have been used as a quarry by the farmers to build the low walls that line the road on both sides, the foundations only being left in the banks; but those which were built of concrete faced with brick, would not pay for the trouble of destroying them, and have therefore been left standing in their places. One of these, a very fine one, faced with brick of the time of Trajan, with moulded pilasters, remains nearly perfect near the seventh mile, just where a path turns off to the left across the fields to the _piscinæ_, which are near the line of the old Via Latina in this part, about half-a-mile from the Via Appia Nova, and forming the carriage-road to Albano through Marino. It left Rome by the Porta Asinaria as it now does by the modern Porta S. Giovanni, which is close to the old gate, but at a much higher level. The Via Latina crosses it in a diagonal line, and runs nearly parallel to it as far as the Torre Fiscale, that is, for about a mile gradually diverging from it.

Wherever the exterior of the _specus_ of the Anio Vetus is visible, it is faced with _Opus Reticulatum_. The reservoirs of this Aqueduct are of the same construction, and this may serve to distinguish those on the slope of the hill at Tivoli from the other aqueducts there.

“The water of this straight branch,” says Frontinus, “coming within the _Porta Esquilina_ along the _Spes [specus] Vetus_, was carried down into the city in the high streams[41].”

This _specus_ is on the high bank of the Tarquins, the outer and lofty line of defence on the eastern side of Rome. On this the wall of Aurelian was afterwards built. After its entry into Rome, the Anio Vetus was divided into several branches, in the same manner as the later aqueducts were.

The right-hand branch, in crossing the Campagna, appears to have run nearly under the Marcian arcade, which was afterwards built on the same line and nearly over it. As we approach near to Rome, there are remains of a reservoir built of large stones a little way down the road, about a hundred yards from the Porta Maggiore. It enters Rome under the wall, almost on the level of the ground; the upper part of the _specus_ was visible in 1868, but in 1869 was studiously concealed by a modern brick wall. It is visible again inside the wall, on the other side of the road, going into the vineyard in which the Minerva Medica stands, while one branch went to the great reservoir near to it, westward of the gate.

Another branch passes along the bank under the wall of Aurelian, and is not visible again until it reaches the Prætorian Camp, where a portion of it was excavated in May, 1868, built of large stones of tufa, under the Porta Chiusa. It may then be traced all round the three sides of the Prætorian Camp, and near the north-east corner there was, in 1868, an opening into it, now closed by a modern wall. It is distinctly visible in several places, especially on the north side of the Camp, where the wall of Tiberius remains perfect, faced with the fine brickwork of his period, whereas the _specus_ under it is faced with _Opus Reticulatum_, probably of the time of the Republic. The wall of Tiberius distinctly stands on the old _specus_. There was an opening into it here also in 1868; but this was also carefully walled up in 1869 under the influence of the Garibaldian panic, which had a bad effect upon the Roman authorities at that period. Remains of a reservoir or _castellum aquæ_ were also found on the surface of the ground on the bank near the Porta Chiusa, with the present wall of Rome built right across it, but this part of the wall has been rebuilt of old materials, and is not exactly in the same line. There are remains of several other reservoirs on the bank at intervals outside the wall in the modern road, and in many places all along the eastern and southern sides of Rome.

Beyond this, near the Porta Nomentana, are the ruins of another reservoir or _piscina_ on the surface of the ground, against the wall. From near the Porta Chiusa another branch went along the old road, which passed through that gate across the inner foss to

the Thermæ of Diocletian, where a part of the _specus_ and two _cippi_, with two inscriptions upon them, naming this aqueduct the Anio Vetus, were found in the year 1861, when the railway was made[42]. These _cippi_ are now in the Vatican Museum.

Another branch went from the reservoir near the Porta Maggiore before mentioned, across the road into the bank on which the arches of Nero stand, near the Lateran, and passed under them apparently into the old _specus_ of the Appia, which runs parallel to and nearly under the arches on the other side. Two small _specus_ or stone pipes can be still seen (in 1872) passing obliquely into that bank; and, as they came from this large reservoir and _piscina_, (or from this direction,) they seem to have belonged to two aqueducts at different levels. A branch of the Marcian may have been brought to the same filtering-place for distribution, and the surplus water carried into the old _specus_ at the lowest level, which was evidently used for receiving and carrying off the surplus water of all the other aqueducts in the same line.

The fifty yards outside the wall added to the three hundred yards between the Cœlian and the Aventine, make up the three-hundred-and-fifty yards above ground, mentioned by Frontinus. In this valley we found it again, in 1869, parallel to the Appia, sometimes on the _agger_ or bank of Servius Tullius, which was used as a substructure for it, in other places on an arcade built up against the tufa wall of Servius Tullius, and faced with reticulated-work.

APPENDIX.

ON SP■ OR SPC■.

For the supposed Temple of Spes, the ruins of an apse in the gardens of S. Croce, of “Venus and Cupid,” (as it is marked in most maps, and as “Speranza Vecchia” in others,) was fixed upon by Piranesi, who carefully examined all that he could with a view of mapping out his aqueducts, according to the knowledge possessed in his time. This building was no doubt a hall belonging to the Sessorian Palace. Others, again, have suggested the so-called temple of Minerva Medica, but this again is a _nymphæum_, or _pantheum_, and not a temple at all. Besides, a further difficulty lies in one being too far south, while the other is too far north.

Canina, in his account of the results of the excavations at the Porta Maggiore[43], and of the tomb of Eurysaces the baker there discovered, just outside of the gate, gives a plan in which he inserts a temple just inside the gate on the southern side, which he calls the Temple of Spes[44]. It is quite possible that this was a Temple of Spes. There certainly was a temple on the site indicated, where the modern guard-house stands; and during excavations carried on there, fragments of a temple of the time of the early Empire were found, consisting chiefly of a fine cornice of travertine.

When, however, the words of Frontinus have to be applied, the difficulties of the theory of his referring to a temple are increased. In the case of the expression last referred to, “_following the specus (spes)_, or, according to one manuscript, _the old specus_, which is obviously the sense,” it is very difficult to imagine what circumstances there were in connection with a temple which could warrant the use of such words; and even in the instance mentioned, where we were noticing the Appian aqueduct, “the expression, the Gemelli, which is a place under the _old specus_ (Spe■s■ Vetus),” is somewhat singular. Granting that a temple once existed just within the wall of the city (which, from the context, must have been its position if any) it is singular that he should use it as a landmark when describing the junction of two streams of water. The remaining three expressions are simply “at the _old specus_ (Spe■s■ Vetus[45]).”

With these difficulties to contend with, it has been thought well to seek a different solution, and this is found in the reading of “Specum Veterem” for “Spe■m■ Veterem,” i.e., the “old _specus_.” With this reading, it naturally follows that it would refer to the old _specus_, or the _specus_ of the Appia and the Anio Vetus; and it is singular that the first time it occurs in Frontinus, the Codex Urbinas[46], only second in authority to the Codex Cassinensis, has the reading “Anienem Veterem,” instead of “Spem Veterem.” What was the true reading of the Codex or Codices from which these two copies were made, it is impossible to say; they are the earliest we have, and it is clear from several other instances that the scribes did not copy with much knowledge of the matter in question: then it was easy to mistake _Spc■_ for _Sp■_. That it was the Specus Vetus which was meant, must rest therefore upon the circumstances which allow of its application to the passages named, and it remains to shew that this is the case.

In the instance under discussion, the water of the Anio is said to flow along its own _specus_, and therefore it would not be probably possible to find an interpretation more suitable as far as this case is concerned. The conduit of the water of the Anio Vetus had “emerged,” as the other aqueducts emerge, near the Porta S. Lorenzo, from the higher ground between the Porta Maggiore and that gate: it must consequently have been carried on a substructure from that point on the outer bank of the original fortifications of Rome, that is, on the high bank on which the aqueducts were carried, and on which the wall of Aurelian was

afterwards built, to the inner bank, on lower ground faced with the tufa wall of Servius Tullius. The names of the gates are matters of dispute, and are quite immaterial; the levels of the ground decide the question[47].

In another place, Frontinus says[48] that several streams of water, and first the Marcia, were carried to the Aventine from the _specus_ (_a spe-cu_), that is from the old _specus_ he had before mentioned on the Cœlian, and obviously from the west end of the Cœlian. The Temple of Spes of Canina and others at the Porta Maggiore, is at least a mile from the Aventine. The only way of giving an intelligible meaning of the passage is that the author refers to the old _specus_ he had before mentioned, as leading along the Cœlian to the Porta Capena. In the excavations made in 1868 and 1869, on the line of the wall of Servius Tullius from the Cœlian to the Aventine, the conduits of three _specus_ were found, two of which must have passed over the arch of the Porta Capena, in order to cross the Via Appia, there a deep foss-way. Two conduits were seen in each of the pits that were dug at intervals along the line, and at the junction with the Piscina Publica under the Aventine they were all three perfect; the lowest one is there cut in the tufa rock under the wall, the other two are on the wall, and partly cut out of it.

Piranesi has preserved a sketch of the _specus_ of the aqueduct, which he supposed to be the Anio Vetus upon its substructure; but he gives no clue as to the exact spot whence that sketch was taken[49]. In its character the masonry is very similar to that of the Marcian, but there are minor differences sufficient to shew that it belongs to an earlier age.

Those who have paid attention to the manner in which ancient books have been transmitted to modern times before the invention of printing, and who are familiar with the use of records and of other medieval manuscripts or transcripts, well know how full of abbreviations they are, and how difficult it often is for the editor to fill up these abbreviations, if he does not happen to know the word intended. The name of _specus_ for the conduit of an aqueduct was essentially a technical word. The first transcribers of the text of Frontinus were not Romans, and did not know the term: hence they filled up the abbreviation _sp■_, or perhaps originally _spc■_, with _spem_ or _spei_, instead of _specum_ or _specûs_. The same thing may have occurred in the text of Lampridius (as mentioned in a note on a preceding page).

The Abbot of the monastery on Monte Cassino (now a public school and public library) has kindly given me tracings of all the passages in that manuscript in which this abbreviation occurs, and I have had them reproduced by photography and phototype on the page annexed. Opposite to this the same passages are given in the Italic characters, and a few words that are necessary to complete the sense in Roman characters. This is followed by an English translation of these passages, and by some extracts from Livy and other authors in explanation.

FRONTINUS DE AQUÆDUCTIBUS.

EXTRACTS REFERRING TO THE ABBREVIATION SPE■S■ FOR SPECUS.

I. _iungitur ei ad s .. em ueterem[51] in confinio ortorum torquatianorum_ et ... novum ramus Augustae, hac tres ... ad Viminalem usque portam deveniunt. I. 5.

II. _ibi rursus emer_ _gunt prius tamen pars julie ad sp■ ... veterem excepta, castelli celii_ _montis diffunditur._ I. 19.

III. _partem tamen sui claudia prius_ _in arcus que vocantur neroniani ad sp■ ueterem transfert_ hi directe per Caelium montem juxta templum divi Claudii terminantur. I. 20.

IV. _rectus vero ductus secundum_ _sp■ veniens intra portam exquelinam in altos rivos per urbem diducitur._ I. 21.

V. _ad gemellos tamen que locus infra sp■ ueterem_, ubi jungitur cum ramo Augustae. II. 64.

VI. _sed postquam nero im_ _perator claudiam opere arcuato ascus[52] (?) excepta usque ad templum_ _divi claudii perduxit_, ut inde distribuetur. II. 76.

VII. _quibus nunc plures aque et imprimis_ _marcia reddita amplo opere a sp■ in auentinum usque perducitur._ II. 87.

Translation of the Extracts from the Treatise of Frontinus on the Aqueducts, containing all the passages in which the abbreviation Sp■ occurs.

I. [The Augustan branch] is joined to it [the Aqua Appia] at the old _Specus_ [or old Spes (?), temple of Hope], in the border of the Torquatian gardens[53]. I. 5.

II. [The three, Marcia, Tepula, Julia] there emerge again; first, however, part (of the water) intercepted from the Julia is poured at the old _Specus_ (or at the old temple of Spes[54]), and so into the reservoirs on the Cœlian Hill, near the temple of the divine Claudius. I. 19.

III. First, however, the Claudia transfers part of its [water] into the old Specus [or at the temple of Spes], on the arches called Neronian[55]. I. 20.

IV. But the direct conduit [of the Marcia, &c.], passing by the old Specus (?) of the Appia (at a higher level, or following the old Hope?)[56], coming within the Porta Esquilina, [the water] is drawn off in the high streams through the City. I. 21.

V. [The Aqua Appia], however, at the _Gemelli_[57], which place is below the old _Specus_ [or below the old temple of Hope (?)], is joined with the Augustan branch. II. 64.

VI. But after the Emperor Nero had carried the Claudian (water), which he diverted, on arched work to the temple of Claudius [or the Claudium], at the _specus_[58] (or at the Temple of Hope?), that it might be distributed thence. II. 76.

VII. By which many waters, especially the Marcia, being supplied in great abundance, are conducted from the _specus_[59] (or from the temple of Hope?) on to the Aventine. II. 87.

Passages in which the Temple of Spes occurs in Livy.

“At the time when this disaster happened, Caius Horatius and Titus Menenius were in the Consulship. Menenius was immediately sent against the Etruscans, elated with their victory. He also was worsted in battle, and the enemy took possession of the Janiculum; nor would the City, which besides the war was distressed also by scarcity, have escaped a siege (the Etruscans _having passed the Tiber_), had not the Consul Horatius been recalled from the country of the Volscians. So near indeed did the enemy approach to the walls, that first the engagement was at _the temple of Spes_, in which little was gained on either side; again at the Porta Collina, in which the Romans gained some small advantage, and this, though far from decisive, yet by restoring to the soldiers their former courage, qualified them the better to contend with the enemy in future[60].”

“At Rome a dreadful fire raged during two nights and one day; everything between the Salinæ (or salt wharf) and the Porta Carmentalis was levelled to the ground, as were the Æquimælian and the Jugarian streets. The fire catching the _temples_ of Fortuna, of mater Matuta and _of Spes_, on the outside of the gate, and spreading to a vast extent, consumed a great number of buildings, both religious and private[61].”

“After this, in pursuance of a decree of the Senate, and an order of the people, an assembly of election was held by the city prætor, in which were created five commissioners for repairing the walls and towers, and two sets of triumvirs: one to search for the effects belonging to the temples, to register the offerings; the other to repair the _temples_ of Fortuna and mater Matuta within the Porta Carmentalis, and likewise _that of Spes_ on the outside of the gate, which had been consumed by fire the year before[62].”

“He agreed with contractors for building a theatre near the Temple of Apollo, and for embellishing the Temple of Jupiter in the Capitol, and the columns around it; he also removed from those columns the statues that stood incommodiously before them, and took down the shields and military ensigns of all sorts which were hung upon them. Marcus Fulvius made contracts for more numerous and more useful works—a haven on the Tiber, and piers for a bridge across it, on which piers Publius Scipio Africanus and Lucius Mummius, censors, many years after, caused the arches to be erected; a court of justice behind the new bankers’ houses, and a fish-market, surrounded with shops for private sales; also a forum and porticus, on the outside of the Porta Trigemina; another porticus behind the dockyard, and one at the _Temple of_ Hercules; also a temple of Apollo Medicus, behind that _of Spes_, near the bank of the Tiber[63].”

It will be observed that all these passages apply to the well-known Temple of Spes near the bank of the Tiber, of which there are considerable remains now in the church of S. Nicolas in Carcere, and do not apply to a Temple of Spes at the Porta Maggiore.

The word _specus_ is used by Vitruvius in the sense of a covered water-course:—

“But if there should be mounds in the middle between the walls and the fountain-head, it must be so contrived that the water-channel (_specus_) be dug under the earth, and poised on the top[64].”

And at a later period by Hirtius:—

“Alexandria is almost wholly undermined with water-courses, and has a _specus_ extending to the Nile, by which water is conveyed into private houses[65].”

III. THE AQUA MARCIA (B.C. 145).

“127 years afterwards, that is, from the building of Rome 608 years, when Servius Sulpicius Galba and Aurelius Cotta were consuls, as the aqueducts or conduits (_ductus_) of the Appian and Anio were much decayed by age, (and also intercepted fraudulently for private purposes,) the business of repairing and reclaiming the said aqueducts was entrusted by the senate to Marcius, who was then acting as Prætor. And because the increase of the population of the city seemed to demand a more ample supply of water, instructions were given to him by the senate that he should carefully examine how far there were other streams which he might be able to bring into the city[66].

“He therefore restored the two old conduits, and introduced a third, _which he caused to be erected with ‘squared stones,’ and larger aqueducts, and carried through them the water which he had obtained for the public service_[67]. Hence it received the name of the ‘Marcian’ from himself, as the author of it.

“The Aqua Marcia has its origin on the Via Valeria at the thirty-sixth milestone, three miles off in the _diverticulum_ (or cross-road), on the right-hand to those going from Rome. On the road to Sublacum, now called Subiaco (_Via Sublacensis_) also (which was paved for the first time under the Emperor Nero), at the thirty-eighth milestone, for the space of two hundred paces on the left-hand side the water lies like a pond, bubbling up in innumerable springs from beneath the stony hollows, and is very green in colour.

“The length of the course from its head to the city is 61 miles, 710 paces;—by an underground channel 54 miles, 247½ paces, on structure above ground 7 miles, 463 paces. Out of this, in many parts away from the city, in the upper part of the valleys, it is carried on arched substructure for 473 paces; nearer the city, from the seventh milestone, on a substructure for 528 paces. In the rest of the work it is carried on an arcade for 6 miles, 472 paces[68].”

“The Marcian ranks fifth in height, and is at its head even in level with the Claudian[69].”

“In the year of the building of the city, 719 (i.e. B.C. 44), Agrippa repaired the three aqueducts—the Appian, the Anio Vetus, and Marcian—and took care to supply the city with many fountains[70].”

“[Temp. Nervæ, (A.D. 96)] the Marcian having been enlarged was carried across from the Cœlian [i.e. its _specus_] to the Aventine[71].”

IV. THE AQUA TEPULA (B.C. 126).

“In the year 627,” writes Frontinus, “after the building of the city, when Plautius Hypsæus and Fulvius Flaccus were consuls, the censors, Cneius Servilius Cæpio and Lucius Cassius Longinus, took care to bring into Rome and the Capitol the stream called the Tepulan, from the Lucullan Fields (which some call the Tusculan[72]).

“The Tepula has its source on the Via Latina at the tenth milestone, two miles off on the right of those going from Rome. Thence it was brought by a separate channel into the city[73].”

V. THE AQUA JULIA (B.C. 34).

“Afterwards Marcus Agrippa collected the natural waters of another stream, at 12 miles from the city on the Via Latina, (2 miles off on the right of those going from Rome,) and so intercepted the stream of the Tepula. To the newly-acquired water the name of Julia was given, from the finder of it; nevertheless the distribution was so divided that the name of Tepula was retained[74].

“The course of the Julia runs for the length of 15 miles, 426½ yards. In work above ground 7 miles; out of this in parts nearest to the city from the seventh milestone (it is carried) on a substructure for 528 yards; the rest on arched work for 6 miles, 472 yards[75].”

III., IV., V. THE AQUÆ MARCIA, TEPULA, AND JULIA.

“Of these [Aquæ], six within the seventh mile, on the Via Latina, are taken up into covered _piscinæ_, where, as though breathing again after their course, they deposit mud. The Julia, the Marcia, and the Tepula, are joined there; of these, the Tepula, (which had been intercepted, and joined to the stream of the Julia,) now receives from the reservoir of the same Julia its proper quantity, and flows out in its own channel, and under its own name.

“These three are carried from the reservoirs on the same arcade.

“The highest of them is the Julia, lower the Tepula, then the Marcia. These come down towards the Viminal, running together beneath the ground, on the same level as the Collis Viminalis, as far as the gate. There they again emerge.

“First, however, a part of the Julia is, at the _Spes Vetus_, taken out and distributed in the _castella_ on the Cœlian Hill; but the Marcia, after the Pallantian Gardens, throws off part of its water into a stream called the Herculanean. This conduit through the Cœlian, being of no use for the houses on the hill because at too low a level, comes to an end above the Porta Capena[76].”

THE PISCINÆ.

To this point, Frontinus tells us, the three aqueducts tend[77], while from this they are carried on the same arcade into Rome. The ruins of these remain visible. Some of them are situated a little way off the south side of the Via Latina, others on the east side of the Via Appia Nova. Of these, two belonging to the Claudia and Anio Novus are subterranean, and are now only to be distinguished as mounds of earth, looking like tumuli. Others are above ground, near that part of the Via Latina [now the road to Frascati and Tusculum], and close to the _Torre di mezza via_, or half-way house from Rome to Frascati, just beyond the sixth milestone of the modern road. Others are at or near the Villa of the time of Hadrian, called _Sette Bassi_ (which is supposed to be a corruption of Septimius Bassus), near the same point. All of these are between seven and eight miles from the City; they are the chief landmarks in tracing the course of the three aqueducts now to be explained, and each of the three comes from its own separate source. The Marcia, the lowest on the arcade, has its origin at the greatest distance from Rome. The Tepula and Julia have their sources comparatively close to the city. The Marcia takes its rise from the Simbrivine Hills, as far removed beyond Tibur to the east as Tibur is from the city, while the latter two find their way from springs in the volcanic region around the lake of Albano.

III. MARCIA.

The source of the Marcia is plainly visible, the exact description of Frontinus pointing to the spot without leaving room for doubt. In one of the numerous little valleys which run down on the north side of the River Anio, feeding this stream with their rivulets, the Marcian has its rise. The lake of S. Lucia[78] in that valley is so called from a small village situated some distance up the slope; along the bottom of this valley the Via Valeria passes. This lake is usually, but erroneously, considered as the source of the Aqua Marcia.

The exact position of the source is about two miles from the village of Marano, but on the other side of the river, on the right of the valley to one looking towards the mountains, and there are still at times pools of water forming here from the springs which emanate from the overhanging hills. The water now falls into two or three rivulets, which run at the bottom of the valley into the river Anio.

The aqueduct, however, when it reached the high road from Rome to Subiaco, along the north bank of the Anio, turned abruptly to the west, followed the course of the road back towards the city, chiefly passing the further or hill side of it, but winding somewhat according to the nature of the ground. After following the road for some seven or eight miles, it crossed the river (close to the monastery of S. Cosimato) and then pursued for some six or seven miles the southern or right bank of the river Anio. Here, at a spot scarcely more than a mile from Tivoli (_Tibur_), the course of the aqueduct left the line of the river, and wound its way in a south-westerly direction towards the _piscinæ_ before referred to; at times on a substructure, and in a few places, where the valleys were deep, on arches, but for by far the greater distance beneath the surface.

The line of the Marcia can be clearly traced along its whole length. The principal source, called Acqua Serena, is a beautiful spring gushing out from the mountain under the present carriage-road, about seven miles and a-half before arriving at Subiaco, clear as crystal and very abundant; it forms a small lake in the valley, and fully realizes the description of Martial. The old _specus_, which had long been concealed by being a foot or two under water and overgrown with weeds, was brought to light in 1869 by the engineer of the Aqua Marcia Pia, in making his new works for the restoration of this beautiful water to use in Rome. He drained the lake a little, and by that means made the _specus_ visible[79]: this _specus_ is then carried to the cliff of the valley of the Anio (into

which the water from the small lake falls), and then follows the course of the valley and the river, until it comes to the monastery of S. Cosimato, a mile from Vico-Varo: here it crosses the river on an arcade of brick. It there leaves the present road, and then is carried in the cliff on the other side of the river until it arrives within two miles of Tivoli, where it again crosses the river (here a deep ravine) on a fine arcade parallel to that of the Anio Novus, and at a very short distance from it. There are very fine and picturesque ruins of both these arcades in the valley called the Valley of the Arches. It then continued in the cliff by the side of the present road, which is on a ledge of the rock or hill overlooking the Anio, as far as the old town of Tibur and the Cascades, behind the present town of Tivoli: to avoid these it follows a serpentine course, winding round the end of the hill, and has a fine reservoir about half a mile beyond the town, on the side towards Rome, below the level of the Promenade of Carciano, by the side of which are considerable remains of a large reservoir or _piscina_, with the _specus_ running into it and from it. This large building is divided down the middle by an arcade, into two nearly equal parts. Some of it is faced with _Opus Reticulatum_ of a peculiar pattern. On the exterior, there are remains of niches and fountains, a villa of some importance having been built at this spot to take advantage of the abundant supply of excellent water[80]. The _specus_ then runs near the cliff below the level of the road to another extensive reservoir and _piscina_ about a mile further on. There are considerable remains of a large building erected on a steep slope just under the cliff, with no upper wall, as the cliff itself supplied its place; but there is on the lower side a fine wall of considerable extent and height, built of large square or oblong stones of the construction called Cyclopean Masonry[81], in this instance differing little from that of the Walls of the Kings in Rome, except that the stones are rather larger, the building-material being not tufa, but a kind of calcareous stone of the country, dug on the spot. This wall has been supposed to be a portion of the fortifications of the ancient city of Tibur, but for this there does not appear to be the slightest evidence or probability. It is simply the natural construction of the material at hand, and therefore the cheapest wall that could be built for the purpose. No cement is used, because none was required; these large blocks of stone require none, and some chippings are used to fill up interstices, as usual when no cement is used. Again the wall turns the corner at both ends; it is not part of a large wall but is complete in itself, as the facing of one side of the reservoir and filtering-place, the interior of which is built of the usual concrete of rough stone and mortar, and lined with cement of the kind which holds water, _Opus Signinum_, used for all the aqueducts. The end is faced with _Opus Reticulatum_, and there are remains of niches against the wall at intervals. It was also more ornamented, because it was intended to be the one seen chiefly; the other side, being near the edge of a precipice, would only appear from a distance, and the large stones were therefore more effective in that situation. There is no reason to doubt that the whole was built together at the time that the Marcian Aqueduct was made, and it was probably restored by Augustus. It may be doubtful whether some caves in the cliff, which formed part of the reservoir, were natural or were cut, and the stone dug out from them. It is altogether a very picturesque and interesting structure. There may be a question also whether there was not a branch from this reservoir to the Villa of Hadrian at the foot of the hill, perhaps a mile lower down.

The _specus_ of the Marcia is visible at the Ponte di S. Antonio over that of the Anio Vetus; and again, but alone, at the Ponte di S. Pietro, and it passes the Ponte Lupo with the Anio Novus, Claudia and Anio Vetus. It then continues, chiefly underground, to the great _piscinæ_ before mentioned, and thence on the arcade into Rome.

After reaching the City, the branch mentioned by Frontinus, c. 87, as being carried across the valley from the Cœlian to the Aventine in the time of Nerva, seems to be the one found during the excavation in 1868, passing over the Porta Capena at a higher level than the Appia, but still at a much lower level than the lofty arcade of Trajan, of which only the bases of the series of piers crossing the valley now remain. The aqueducts following this line had all to cross the Via Appia, here a foss-way, on the arch of the Porta Capena. This southern branch of the Aqua Marcia is probably the one that can be traced along the side of the cliff of the Pseudo-Aventine, after it had been repaired and brought again into use, for it must be remembered that at one time, as Frontinus says, it ended at the Porta Capena.

The conduit and arcade were rebuilt by Augustus, as recorded on the inscription on his arch at the Porta S. Lorenzo, and in the sixth decree of the Senate, on the subject of the aqueducts. This branch arcade of Augustus is there expressly named as distinct from the others, all needing repairs at the time of this edict. The consuls are charged to see to “the repairs, at the expense of the city, of the streams, conduits, and arches, of the Julia, Marcia, Tepula, Anio; also of those streams and arcades which Augustus Cæsar had rebuilt.”

A branch of the Marcian aqueduct was carried along the _agger_ into the Prætorian Camp. Some leaden pipes were found there in 1742, with an inscription upon them, recording that they were of the time of the Emperor Macrinus (A.D. 217). This probably indicates either a renewal of the pipes, or an additional supply of water. The garrison in that camp was twelve thousand men, and a large supply of water must have been required for their use[82].

The excellent qualities of the Marcian water are mentioned by several of the classical authors, and were celebrated for a long period; they were known in England in the time of Shakespeare, as appears from the following passage in CORIOLANUS, _Act_ ii. _Sc._ 3—

Brutus loquitur.—"What stock he springs of, The noble house of the Marcians; from whence came That Ancus Marcius, Numa's daughter's son, Who, after great Hostilius, here was king: Of the same house Publius and Quintus were, That our best water brought by conduits hither; And Censorinus, darling of the people, And nobly named so, being censor twice, Was his great ancestor."

There is a slight anachronism here. Coriolanus lived in B.C. 489, and the Marcian aqueduct was constructed in B.C. 145, more than three hundred years after his death. Marcius Censorinus also, who was twice Censor (the only Roman who filled that office twice), lived B.C. 294.

In the thirteenth century, the church of S. Bibiana is incidentally mentioned as being near the arcade of the Marcian aqueduct[83]. In some excavations made in the year 1871, a portion of the Marcian arcade, built of the usual large squared stones, was shewn, passing under some high ground to the north of the Porta Maggiore, within the wall of Aurelian, in a direction to join the bank on which that wall is built, and passing between the Minerva Medica and the wall in that part. This is very near the church of S. Bibiana.

IV. TEPULA.

The sources of the Tepula and the Julia are in the valleys on either side of the promontory on which the modern town of Marino stands, the ancient Castrimœnium (under the village of Rocca di Papa). That of the Julia is on the south side, and almost close under the crater now the Alban Lake. The Tepula rises near the bottom of the valley which comes down from the hills in the neighbourhood of Grottaferrata, and along which the Via Latina passes. This lies somewhat nearer to Rome than the source of the Julia; but the Julia joined it before it had advanced far, and thus the expression of Frontinus, "Marcus Agrippa intercepted the Tepula[84]," is explained. The waters, therefore, flow into the same series of reservoirs and cisterns which received the Marcian after they enter Rome.

Under the account of the Julia, the _Aqua Crabra_ is mentioned. This is the little stream into which the water of the Julia and Tepula falls; which is united at the foot of the hill on which the town of Marino stands, to another stream called the Marrana, and the united water is now generally called by the latter name only[85]. Frontinus mentions several reasons why it was not made use of for supplying the city with water; but it was brought into Rome in the twelfth century as a small mill-stream.

Frontinus also says that the Tepula had its source at ten miles from Rome on the Via Latina, with two more miles to the right on a cross-road[86]. Ten miles on the Via Latina brings us near to Tusculum, at the tenth mile is the Casino de Ciampino, from which starts a cross-road to the right; and at two miles from that point we arrive at the springs called Fontanaccio, before reaching Grotta Ferrata, but close under that village. It follows that the source of the Tepula was at this place, now called Fontanaccio. The spring comes out under a cliff of the rock of lava near the road, and has a modern washing-cistern in front of it; but behind this the ancient work can be seen, with openings into a reservoir in the cliff. This is probably contemporaneous with the time that the conduit of the Tepula was made. The supply of water is small, but of good quality.

As the Aqua Tepula supplied only the Regiones in the northern part of the city, it seems to have passed into the _castellum_, the remains of which may still be seen in the city wall near the Porta S. Lorenzo, evidently built upon an old _agger_ before the Aurelian wall was erected[87]. It, however, has been a house as well, the lower part only being used as the reservoir for the water, and the upper part, which is large and important, for chambers. The front of this house, or _castellum aquæ_, still forms part of the city wall. It has been much disfigured, and the old drains walled up during the _restorations_ (!) of 1869.

On the level of the first floor, in which is part of the reservoir, is a row of corbels to carry a wooden gallery or _hourd_, probably an external passage for the use of the Aquarii, behind which the _specus_ runs at the same level. Immediately above the line of the corbels which carried the floor of the gallery or balcony, is a row of large arches; but these are merely the arches of construction found in most walls of the period. At the south end of this line of corbels, which mark the extent of the _castellum_ in that direction, there is an angle, and the wall recedes a few feet. In this angle is the _specus_, corresponding in form and dimensions with that of the Aqua Tepula in other parts; it can be seen entering into the reservoir behind the line of corbels. Within the wall are the usual marks of a reservoir of water: the tartar deposit remains visible in the corners of the chambers cut through by the wall of Aurelian, or

by the engineers of the Acqua Felice, whose _specus_ runs behind it on the bank within the wall which formed the front of the house. The _specus_ of the Acqua Felice is here at rather a higher level than the Marcian arcade, with the three _specus_ upon it, although at the “Sette Bassi,” five miles from Rome, and near the _piscinæ_, it is at a lower level. On the bank just above the level of the ground are the water-drains (hidden by the restorers in 1869) for carrying off the superfluous water into a large subterranean drain which runs under the gateway, and which is still in use for purposes of irrigation.

V. JULIA.

Frontinus states that the source of the Julia was at twelve miles on the Via Latina, with two more miles added on a cross-road to the right[88]. The twelfth mile is at Frascati; from thence, by a cross-road to the right, we arrive at the bridge of the Squaricarelli, and at the copious springs called the Fontanile, exactly two miles from the starting-point at Frascati. This must, therefore, be the source of the Aqua Julia.

The swampy ground in which the source of the Angelosa or Aqua Julia is found, is full of springs, like the Lucullan fields, from which flow the Appia and the Virgo, and from it run also the streams called di Monte Fiore and la Marrana di Marino.

This ground is on a high level on the Monte Fiore e dell Aglio (the Mons Algidus of the ancients), or “The hill of flowers or of garlic;” and the springs come from the gardens of the modern Villa Aldobrandini, at Frascati. Canina cleared out the ancient _specus_, which had a curved vault, almost oval (_a capanna_).

This source of the Julia is on the left-hand side of the road from Grotta Ferrata to Marino, about a mile above the former, and nearly the same distance below the latter. The water gushes out from the foot of the rock and passes under the road to a _lavacrum_, or washing-place, at a lower level on the opposite side of the road, and then falls into the Aqua Crabra, which passes at the foot of the cliff many feet lower down. A part of the water of the Julia, before it goes into the _lavacrum_, is carried to the right in a _specus_ to Grotta Ferrata. This is ancient, but has been restored to use, so that it looks modern. Below Grotta Ferrata, the _specus_ has been destroyed in many parts; but remains of it may be seen close to the ancient fortified villages called Pagus Lemonius (on the maps Castellaccio, a small castle). It is ten miles on a branch of the ancient Via Latina, and between the present roads to Frascati and Grotta Ferrata. In a part of the fortifications of this village is a _castellum aquæ_, or reservoir of the Julia, and near it part of the _specus_, on an arcade on the brow of the hill. This _specus_ is built of rough stone, and faced with a rude early kind of _Opus Reticulatum_, more rude indeed than might have been expected at its date (B.C. 34), and not nearly such good work as the Muro Torto, but more like the Emporium. The reservoir is of the same character, but part of the _specus_ in the fortifications is carried on brick arches which agree with that date; the brickwork is not of the time of Nero, to whom it has been attributed. A _specus_ of rough stone follows the line of the hill to the Marrana, after the junction of that stream with the Aqua Crabra, close to the point where the water from that stream enters a tunnel of the Aqua Julia. After it emerges from this tunnel, it arrives at the _castellum_ or _piscina_ in which the water of the Julia was received before it was carried on the Marcian arcade. This _piscina_ is about two miles nearer to Rome, close to the point of junction between the roads to Frascati and Marino, through Grotta Ferrata, and near to the other _piscinæ_.

Frontinus says that the AQUA CRABRA flowed past the head of the Julia, but was excluded from it by Agrippa[89]. We find this stream coming from that part of the hill on which the village called Rocca di Papa is situated, passing near the head of the Julia at Fontanile, now Angelosa, and sometimes mixing with the springs there. It has one of its sources in the grounds of the Villa Torlonia, at Frascati. All these three streams now fall into the river Anio.

Near Rocca di Papa an arcade, or bridge of ten arches, of silex or flint, covered with brick, passes over the Aqua Crabra to carry some aqueduct, probably a part of the Julia. This arcade is called Arcioni, [‘the arches.’]

There are some remains of another reservoir within the wall of Rome, on the bank between this and the Porta di S. Lorenzo, which seems to have belonged to the Julia: the _specus_ of the Marcia, with that of the Tepula and remains of that of the Julia over it, are visible on an arcade a little beyond, close to the gate. The lower part of a fine brick wall with bold buttresses, of the usual character of a _piscina_ or _castellum aquæ_, are visible, and this faces the present Wall of Rome, almost touching it, so that this has been built since the _piscina_, but that not being exactly in the same line it could not be used. The _piscina_ of the Tepula being on the outer side of the bank or _mœnia_ came into the line of defence of Aurelian, and was used as part of his wall; that of the Julia, being on the inner side of the bank, was too much within the line to be used.

The Castellum Aquæ Juliæ, or chief reservoir of the Julian Aqueduct, is usually, but erroneously, said to have been the one situated on high ground near the church of S. Maria Maggiore, where the picturesque ruins stand, usually called the “Trophies of Marius,” because those trophies were hung under two of the arches there, until they were removed to the Capitol. A lofty arcade carrying a _specus_ at a high level passes across the valley, from the reservoir near the Porta S. Lorenzo to this point. This arcade is of the first century, built of the fine brickwork usual at that period, and agrees with the time of Frontinus; but the only aqueduct that was high enough to have carried water to that spot was the Anio Novus.

This great reservoir was rebuilt by Alexander Severus, and called a Nymphæum, being given as such on one of his coins. This name is rather a vague one; but it is evident, from some excavations made in 1871, that there were extensive _thermæ_ of the Emperors of the third century near this place.

From this lofty reservoir the distributing channels may be seen branching off in different directions, one going to the Thermæ of Titus, towards the reservoir called the Sette Sale, another going in a different direction.

This Nymphæum (?) is on lower ground than the outer wall, though still on ground so high that the only water that could reach it was that of the Claudia and Anio Novus, of which part of the arcade remains between it and the reservoir on the high bank. From that point the ground descends gradually and gently along the line of the _agger_ of Servius Tullius either way, and still more towards the interior of the city. The aqueduct, therefore, could not pass underground and then _emerge_ in this part. The Porta Esquilina of the inner wall was on the same level, or nearly so. The Porta Tiburtina of the inner wall was near the _thermæ_ of Diocletian, with a gradual and gentle descent to it along the line of the _agger_. The only possible explanation of the text of Frontinus is that the same names of the gates in the inner wall were applied to those in the outer wall on the same roads.

A piece of leaden pipe, with an inscription upon it, was found at the Porta S. Lorenzo, which gives the names of Dolabella and Silanus as Consuls; this fixes the date at A.D. 10, and shews that the Marcian water was conveyed in leaden pipes at that point in the time of Augustus. The stone _specus_ was carried over the gate, as we see by the remains of it in the wall, and the inscription upon it recording repairs by Augustus. The one upon the leaden pipe is given by Gruter[90].

Another leaden pipe was found by Panvinius on the site of the Prætorian Camp, with an inscription, given by Gruter[91], which records that it conveyed the Marcian water to that point.

Three aqueducts are mentioned in other inscriptions found during the excavations near the railway station in 1869[92]; the _three_ aqueducts intended can hardly be other than the Marcia, Tepula, and Julia. The upper one only was excavated; but if the noble Roman princes who conducted this excavation had dug a little deeper, they would probably have found the other two _under_ the one that they had discovered. These three _specus_ must have been carried along and in the _agger_ of Servius Tullius.

To reach that part of it on the side of which these _cippi_ are found, they probably went along the side of the road that passed on the south side of the Prætorian Camp, on which was the gate called Porta Chiusa. Close to this gate remains of a large reservoir were found in the researches of 1869 on the bank, with the Wall of Rome carried right across it; but this part of the wall is medieval, built of old materials, and it is probable that, originally, the front wall of this reservoir was included as part of the wall of the city, in the same manner as that of the Tepula near the Porta S. Lorenzo. This reservoir, with the Porta Chiusa by the side of it, and the road from it to the _agger_, at the place where the _cippi_ were found, is now in the garden of the Baron Grazioli.

VI. AQUA VIRGO (B.C. 21).

This Aqueduct was made by Marcus Vipsanius Agrippa to supply water to his Thermæ, on the south side of the Pantheon, which was the hall of entrance to them.

Frontinus writes:—

“The same (M. Agrippa) when he had been consul for the third time, and when C. Sentius and Quintus Lucretius were consuls, that is, thirteen years after he had brought down the Julia, he brought the ‘VIRGO’ also, the water of which was collected in the Lucullan fields[93].

“The Virgo begins on the Via Collatia, at the eighth milestone, in some marshy places: a cemented wall [_signino[94] circumjecto_] being placed round it, to retain the bubbling waters; the source was increased by many other additional supplies. It comes for a length of 14 miles and 105 paces. Out of this,—by a subterranean stream 12 miles, 865 paces; above ground for 1 mile, 240 paces, of which it runs on a substructure in several places for a distance altogether of 540 paces; on arched work 700 paces. The

channels of the additional supplies of the subterranean stream make 1 mile, 405 paces[95].”

The Virgo has no reservoir, i.e. Piscina ... “The arches of the Virgo have their commencement beneath the Lucilian (or Lucullan?) gardens. They end in the Campus Martius, along the front of the Septa[96].”

The Virgo was the seventh in height as to level (c. 18).

The road now called Via Collatia, or Collatina, where the Aqua Virgo has its origin, is between the present roads to Tivoli and Palestrina; it turns off to the left or north of the highway now called Via Prænestina, just beyond the ruins called Torre de’ Scavi or de’ Schiavi, about three miles from the city. But this is an alteration; the old road from Rome to this point in a foss-way may be traced _behind_ the tower in the meadows, with the subterranean aqueduct running under and in the southern bank of it, as traced by the respirators or ventilating shafts. There are remains of very ancient tombs at intervals all along the line of this old road, which goes straight towards a postern-gate midway between the Porta Maggiore and the Porta di S. Lorenzo. This must be the Via Collatia of Frontinus.

Close to this road, at eight miles from Rome, near the ruins of Collatia, there are several springs in marshy ground, from which the water is collected in a series of reservoirs, just below the level of the ground, the vaults over them being sometimes above ground; from these small reservoirs separate short conduits run to the same point, the great central _castellum aquæ_, part of which is a cave in a rock, with a larger semicircular basin built out in front of it, over which passes the cross-road from the Via Collatia to Salone.

The line of the _specus_ can be distinctly traced from this reservoir near its source to the city by the respirators over the wells. The smaller _castella_, or cisterns, at the sources are also still in use.

About four miles from Rome, on the road now called Via Collatia, or Collatina, a portion of the Aqueduct was rebuilt under Benedict XIV. in 1753, as stated on an inscription upon it. It is here carried across a shallow valley, on an _agger_ built of rough concrete faced with brick, for about a quarter of a mile. At the further end is a conduit-head, or a modern _castellum aquæ_. This is a small oblong building with a semicircular head erected under Pius VI. in 1788, by Joseph Vai; and the conduit was continued by him for the length of 175 feet, also stated in an inscription upon it[97].

From this point there is a branch to the south for a short distance, with two respirators visible in the field; but this, though appearing like an additional source, is only a branch leading to an old fountain of a villa.

The main line comes from the north along the bank of the Via Collatia, as shewn by the respirators, at regular intervals of about a hundred yards. These are mostly round masses of concrete with round heads; but some are dwarf pyramids, one of which, numbered “40,” has been rebuilt in 1866. The surplus water is carried into a brook which runs by it, and receives its chief supply from it.

The _specus_ or conduit of the Aqua Virgo passes along the line of the old road in a direct line west, towards the Porta Maggiore, until within about half a mile from that gate; then it makes a great detour to the north, passing under the modern Via Tiburtina, and eventually enters Rome through the Pincian Hill a little to the north of the Spanish steps, and there is a reservoir for it at the end of a short street called the Via del Bottino. It then goes to the present fountain of _Trevi_, passing at the back of the houses in the Via del Nazareno, where it may be seen in several of the courtyards. In one of these, on the left hand of the street, is an inscription recording its repair by Claudius[98]; in another, on the right, is an ancient lavatory below the level of the street. A branch passes under the Via dei Condotti carried in leaden pipes, enclosed in a brick _specus_; this branch is the one that led to the Thermæ of Alexander Severus, which were situated to the north of the Pantheon. The main line supplied those of Agrippa, for which this aqueduct was made. The Aqua Virgo chiefly supplies the fountains and houses in the Campus Martius, or lower city, and the main stream terminated originally in front of the Septa[99], considerably to the south-west of that fountain. In some excavations made in the summer of 1871, a portion of it was found in the Piazza di S. Ignazio. This original termination was at the north end of the Septa, very near the Pantheon.

This aqueduct was restored by Pope Hadrian I., A.D. 772-795, after it had been damaged by the Goths. It was afterwards repaired by several subsequent pontiffs, especially by Boniface IX., A.D. 1389, and by Nicholas V. in the fifteenth century. It now supplies the fountains in the Piazza Colonna, erected in 1574; at the Pantheon, restored in 1711; several others of the seventeenth century; and that of the _Trevi_, erected by Benedict XIV. in 1730.

Near the source of the Virgo passes an abundant stream, also called Marrana; but this has mineral properties, and was therefore carefully avoided in forming the aqueduct for the Virgo. Pliny says[100] that there was a stream which was abhorred by the Virgo, and for that reason the water was called the Virgin. This stream was called by him _Rivus Herculaneus_, some say for its salubrious qualities, because Hercules was the god of health; others because it was a strong stream. There is little doubt that this is the stream here described. The same name of Herculanean is given by Frontinus to the stream now called Marrana[101] in two places, because it was also a strong stream.

VII. THE ALSIETINA (A.D. 10), AFTERWARDS MADE THE AQUA PAOLA.

Frontinus says of this water, “What could have induced Augustus, that most careful of emperors, to bring in the water of the ALSIETINA (which is called Augusta) I do not well know; for it is not pleasant to the taste, and therefore of no use for the people. It may be, however, that when the work of the Naumachia approached completion, in order not to divert the more wholesome water, he introduced this for the special purpose, and gave the surplus to the adjacent gardens and territories.

“It is the custom, however, in the Transtiberine Regio, when the bridges require mending, and there is no water forthcoming from the city side, to make use of this for supplying the public springs, as a matter of necessity.

“It begins in the Alsietine lake on the Via Claudia, at the fourteenth milestone, about six miles and a-half off on the right hand. Its course is in length 22 miles, 172 paces, and over arched work 358 paces[102].”

“It is the lowest of all as regards the level, supplying only the Transtiberine Regio, and the places adjacent[103].”

“The manner of beginning the Alsietine aqueduct is not described in the commentaries, nor can it now be found with certainty; it begins from the Alsietine lake, and then about the _Cariæ_ receives water from the Sabatine lake also, as the Aquarii regulate. The Alsietine gives 392 quinariæ[104].”

The lake formerly called “Lacus Alsietina,” now called Lago di Martignano, is situated on the hills on the western side of Rome, between the Via Aurelia and the Via Claudia, (not far from the old carriage-road from Florence to Rome). It is about 679 ft. above the level of the sea; and as Rome is only 204 ft. at the Porta Maggiore, the lake is 475 ft. above the level of Rome at that high point. There is another small lake about a quarter of a mile from, and a little above the level of, the Alsietina, called Strachia Capra, which has recently been drained by a tunnel in imitation of the _emissario_ from the lake of Albano. The water in the Lacus Alsietina has also been very much lowered in the same manner[105]. In consequence of this reducing of the level of the water, the _specus_ of the aqueducts are now brought to view, being on the bank and above the present level of the water, so that they can distinctly be seen and entered into[106].

To begin with the highest, the _specus_ of the Aqua Paola begins in the upper lake, and forms a junction with the water from the Alsietina Lake, near the bank of the latter, at the south end of that lake. The _specus_ of the Alsietina of Augustus is a tunnel cut in the rock[107]. The Lacus Sabatina[108] is at the elevation of about 523 ft., and therefore 156 ft. below the Alsietina. Augustus drew an additional supply of water from this lake, and this portion only of the aqueduct of Augustus was restored by Trajan. The water for this was not drawn from the lake itself, but from the springs that supply the lake on the western shore, the side most distant from Rome. Some of the work of the time of Trajan is visible there. The _specus_ of the Alsietina has been traced to the point of junction with the Aqua Paola (this water having been restored to use by Pope Paul III., A.D. 1540), and it still supplies the district of the Trastevere. It does not appear that Trajan used the water of the Alsietina at all, but the engineers of Pope Paul evidently did so; a tunnel, or _specus_, from that lake having been made in the time of Pope Paul, the entrance to which remains, with the grooves for a flood-gate[109]. After the junction with the Aqua Paola, the old wells can no longer be traced; their place is supplied by the constructions called _respirators_, each of which is a small square structure surmounted by a pyramid. These are evidently built over the wells, and very rudely constructed of the stone of the country, worked rough. When we arrive at the Osteria Nuova,—which is near the site of the ancient city of Cariæ[110], mentioned by Frontinus, and the old village of S. Maria in Celsano, the point of junction of the Alsietina and Sabatina,—there are evident marks of another junction of aqueducts there. The house itself, now used as an _osteria_ or hostelry (_auberge_), is made out of an ancient Castellum Aquæ, as is frequently the case with similar houses in the country round Rome, and sometimes even within the walls. At about half a mile from this _osteria_, in a hollow, is a white house called Casale Bianco; and close to this is a fountain, supplied by a spring which runs into a _specus_. This water, being one of the sources of the Aqua Paola, passes through the hill at a considerable depth. At about half the distance between this and the _osteria_ is a remarkable passage for the Aquarii into the tunnel by a very steep descent, passing sideways across the _specus_ of the Aqua Paola, and going on to a much greater depth to the Aqua Alsietina[111]. This passage is 150 ft. in

length from the surface of the hill, and 70 ft. in perpendicular depth, with ninety steps, of which only a few at the top are visible; the others are covered with earth. The water still runs through the upper _specus_, and is still in use, but not through the lower one[112].

From the valley beneath the sloping passage for the Aquarii, near the Osteria Nuova, Nibby[113] traced the Alsietina as a tunnel cut in the tufa rock, a part of which he saw near an oil mill. The _specus_ then followed the low ground from the tenements of S. Niccola, Porcareccina, Maglianella, and from the Villa Panfili, to the principal gate of the monastery of _S. Cosimato_ (or SS. Cosmas and Damian in the Trastevere), where it is stated by Cassio[114] that the _specus_ was found in 1720, about thirty feet underground. The Naumachia of Augustus is said to have been near this monastery.

The complaints of Frontinus appear to have been listened to by the Emperor, and great changes and improvements were made in this aqueduct under his direction, in the time of Trajan; this is in fact the same as the Aqua Trajana (see X.), and the water still comes from the Lacus Sabatina, but not from the Alsietina. In going from Rome, the respirators can be followed across Monte Mario, and near the high road that passes over Ponte Molli, to the point of junction about ten miles on the road to the Cariæ [now Osteria Nuova]. Here the respirators cease; but their place is supplied by a line of old wells descending into the subterranean _specus_, which follows the line of the _old road_. This is not always the same as the new one. The other branch, which supplied the Naumachia, was the only one made in the time of Augustus. Paul V. repaired this aqueduct along the whole line, restored it to use, and put up in various places inscriptions recording this, in which he calls it the Aqua Alsietina[115]. The last of these is on his fountain at the mouth of the aqueduct, where the water still gushes out in great abundance, as it did in the sixth century, when it was observed by Procopius; this is on the Janiculum, above S. Pietro in Montorio, the highest ground in Rome.

VIII., IX. THE CLAUDIA AND ANIO NOVUS (A.D. 52).

“Afterwards Caius Cæsar, (Caligula,) who succeeded Tiberius, considered seven aqueducts scarcely sufficient for public purposes and private amusements, and began two new aqueducts in the second year of his rule as Emperor, when Aquilius Julianus and P. Nonius Asprenas were consuls (i.e. A.D. 38), in the year of Rome 789, which work Claudius in a most splendid manner finished and dedicated, on the calends of August, in the year of the city 803 (i.e. A.D. 52), when Sulla and Titianus were consuls[116].

“To one, which was brought from the springs of Cæruleus and Curtius, the name of _Claudia_ was given. This one is next in order of excellence to the Marcian.

“The other, because two streams of the Anio had begun to flow into the city, so that they should be more easily distinguished by their names, began to be called _Anio Novus_. It ruins all the others[117]. To the former Anio the cognomen of _Vetus_ was added[118].

“The Anio Novus and Claudia are carried from the _piscinæ_ upon higher[119] arches, so that the Anio is the highest of the two. Their arches come to an end after the Pallantian Gardens, and thence they are carried down in pipes for the use of the city.

“But first of all the Claudia transfers a part of its water on to the arches which are called the Neronian, at the _Spes (Specus) Vetus_. These, being continued in a direct line along the Mons Cœlius, are terminated close to the temple of Claudius. They disperse the quantity which they had received either about the ‘Mons Cœlius’ itself, or in the Palatine, in the Aventine and the Transtiberine Region[120].”

VIII. THE CLAUDIA.

“The Claudia begins on the Via Sublacensis[121], at the thirty-eighth milestone, about 300 yards off the road towards the left. There are two very large and beautiful springs, one called Cæruleus, from its blue appearance, the other Curtius[122]. It receives also the spring which is called Albudinus, of such excellence, that when there is need of adding it to the Marcia, the latter loses none of its quality by the addition. The spring of the Aqua Augusta, because the Marcian seemed to be sufficient for itself, was turned aside into the Claudian; nevertheless it was retained as a protection for the Marcian, but so that the Augustan might be added to the Claudian, if the channel of the Marcian was not capable of receiving it[123].

“The channel of the Claudia is 46 miles, 406 paces in length; of this, 36 miles, 230 paces is by a subterranean course: on work above ground 10 miles, 176 paces, and out of this on arched work, in many places in the upper part, 3 miles, 76 paces; and near the city from the seventh milestone, by a substructure of channels for 609 paces, on arched work 6 miles, 491 paces[124].

“The Claudian was the second in height as to level[125].”

IX. THE ANIO NOVUS.

“The Anio Novus, at the forty-second milestone, on the _Via Sublacensis_, at _Simbruinum_[126], is taken out of the river, which, since it has about it cultivated land in a rich territory, and so very loose banks, flows muddy and turbid even when uninfluenced by violent rains; and therefore at the very entrance of the channel is placed a cistern for the mud (_piscina limaria_), so that the water on its way from the river to the _specus_ should settle and become clear. From this cause also when heavy showers come down, the water flows into the city in a muddy state.

“There is joined to it the _Rivus Herculaneus_[127] which rises on the same road at the thirty-eighth milestone, in the same neighbourhood as the springs of the Claudian, on the other side of the river and the road. This is very pure by nature, but when mixed it loses the advantage of its freshness.

“The channel of the Anio Novus is in length 58 miles, 700 paces. Out of this 49 miles, 300 paces is by a subterranean channel;—on work above ground 9 miles, 400 paces; out of this on substructure or on arched work in several places in the upper part 2 miles, 300 paces, and nearer the city, from the seventh milestone, on a substructure of channels 609 paces, on arched work 6 miles, 491 paces. These are the highest arches, elevated in some places 109 feet[128].

“Nor was it enough for our Emperor [Nerva] to have restored an abundant and pleasant supply of water in the other aqueducts; he thought he saw his way to getting rid of the bad qualities _even of the Anio Novus_, he therefore ordered the _source to be changed from the river_, which was now left alone, and taken instead _from the lock in which_ the water was most pure, and which _is situated above Nero’s villa on the lake_ (_super villam Neronianam Sublaquensem_[129]);” i.e. at Subiaco, now a medieval castle and a modern town.

“But the water of the Anio Novus often spoilt the rest, for since it was the highest as to level, and held the first rank as to abundance, it was most often made use of to help the others when they failed. The stupidity, indeed, of the Aquarii was such that they introduced this water into the channels of several others where there was no need, and spoilt water which was flowing in abundance without it. This was the case especially as regards the Claudia, which came all the way for many miles in its own channel perfectly pure, but when it reached Rome, and was mixed with the Anio, lost all its purity. And thus it happened that most of the streams were not in fact helped at all by the addition of the extra water, through the want of care on the part of those who distributed it[130].”

THE NERONIAN ARCHES.

“Amongst those abuses which seemed to require reform, may be mentioned what took place regarding the supply to the Cœlian and Aventine hills. These hills, before the Claudian was supplied to them, were accustomed to use the Marcian and Julian; nevertheless, when the Emperor Nero gave them the Claudian raised to a greater height on the series of arches extending to the Temple of Claudius, where it was distributed, the older streams, instead of yielding an increased supply, were lost altogether. He made no new castella [for the Claudian], but used those which were there, and which retained their names, although the water brought to them was different[131].”

THE RIVER ANIO.

The highest source of the river Anio, or Aniene, is in a gorge in the highest part of Mount Cantaro, about 63 miles from Rome. This spring never fails in the hottest and driest weather, and is always cool; it is situated in the close or (_serra_) of St. Antonio, and is called _La Canala_, or the canal at the gate of the small castle or fortified village of Filettino. Pliny says[132] that it rises in the territory of Treba[133]. In going from Filettino towards Trevi the road has an ancient pavement, and on the left-hand side is a magnificent substructure of Cyclopean character called _Mura Saracine_, against the cliff. In 1857 Signor Gori saw some of the large stones of this fine ancient substructure thrown down to the banks of the stream, to make the foundations of a small bridge across it. The stream receives several accessions from other springs in its course, two from a cave called Pertusu, the small limpid stream called Suria, on the hill of Trevi, and another called Capo d’Acqua. The Anio thus augmented falls in two cataracts, or cascades, near Pertusu, and passes under the Ponte delle Tartare with much violence. This bridge is a natural arch of rock formed by the force of the water piercing it. The river then passes on through a gorge in the mountain-pass in small waterfalls, especially at a place called Pendema, where in 1855 an ancient mosaic pavement and a wall of reticulated masonry were found.

At the two bridges of Communacchio (_comune acqua_), where an amphitheatre of mountains and the castle of Valle-pietra are situated, another stream coming from the mountains of the Trinitá and Autore, the highest in that district, joins the Anio.

In the basin of Valle-Pietra, two fine cascades fall over the massive rocks and unite in a single stream. From the bridge of Communacchio a road leads to Arcinazzo, situated in a large plain, surrounded by the mountains, with several roads leading into it. One of these from Palestrina, passing by Piglio, is an ancient paved road, and some persons consider that an arcade of Cyclopean masonry, near Guarcino, carried an aqueduct to the _thermæ_ there. On the south-west side of this plain are the ruins of an imperial villa, commonly called of Nero; but two inscriptions found there upon leaden pipes in 1860, shew that it was of Trajan[134]. Great quantities of marble were dug up here in the time of Pius VI., A.D. 1795.

The river passes below the monastery of S. Benedict, called the Sacro Speco, and a little lower down, the monastery of S. Scholastica, both of which stand on the brink of a precipice, over which the Anio makes a large and picturesque waterfall, and passes under the bridge of S. Mauro or Piedilago, where the rocks approach so closely as to leave only a narrow passage, which was formerly closed by a gigantic wall, forming a long lake or lock. The stream now passes through the ruins of the wall, the demolition of which was caused in 1305 by two ignorant monks, who pierced a hole at the foot of the wall, the result being that the whole country was inundated up to the walls of Rome, and serious mischief done, as recorded in the anonymous chronicle of the monastery[135].

On the banks of the lake are the ruins of a villa of early character, called Casa de' Saraceni and Carceri, with a _nymphæum_ and baths. At Pianigliu, are other ruins on an enormous scale.

Subiaco is more than two thousand feet above the level of Rome, and all the foregoing description applies to the part of the river above Subiaco. In all this upper part of the stream, the river Anio has very much the character of a large mountain-torrent rushing through the rocks with great violence. It usually appears to be a clear stream of beautiful water, excepting in time of floods, when the clayey soil is brought down into the stream and makes it muddy. To guard against this evil, Nero made his great lakes, which do not correspond at all to the usual English idea of a lake, by which is commonly understood a considerable sheet of water, like the Swiss lakes or the lakes of Westmoreland, Scotland, and Wales. The Roman word _lacus_, and the modern Italian _lago_, may mean a lake of this description also; but it includes a reservoir of water of any kind. We are expressly told in the _Breviarium_, at the end of the Catalogue of the Regionaries, that a _lacus_ is a well, _puteus_, and the numerous _lacus_ of that Catalogue are the same as the _castella aquarum_ of Frontinus, within the walls of Rome. These justly-celebrated lakes of Nero are in fact portions of the river Anio, intercepted in a gorge of the rocks about a mile above Subiaco, and are formed by cutting away some large pieces of the rock on each side in large masses, and with these building a great high and massive wall across the stream, forming an effectual barricade or dam to stop the water and raise it to the level of the top of this great wall. There were three of these walls across the stream, over each of which the river fell in tremendous cascades. The first loch (_lacus_) commenced at the Mola di Ienne, where the first great wall of enclosure is situated. The second at the cascade of the river, under the great monastery of S. Benedict, and called "the Sacred Specus," from a cave in which the saint is said to have lived, extends to the bridge called Ponte di S. Mauro, where the _specus_ of Trajan commenced. The third is from the Ponte di S. Mauro, through a gorge, where the wall of enclosure is visible. Here was the Piscina Limaria of Claudius, and the _specus_ of the Anio Novus originally commenced at the Emissarium, restored by Cardinal Barberini. This was made by Claudius, but was abandoned by Trajan, because the earth from the adjoining fields had fallen between the river and the _specus_.

The Villa Sublacensis of Nero was below the level of the upper lake or loch, as mentioned by Frontinus. This was just above the present bridge called S. Mauro or Piè-di-lago, which seems to be made upon the two ends of the dam. This dam, wall, or barricade, was quite 150 feet above the surface of the water in ordinary times. The bridge is still 144 feet above the water by measurement, and the _specus_ is nearly ten feet higher. This _specus_ or conduit is cut in the rock of the cliff on the side of the valley, at the level at which the water originally stood in this lake or loch; the wall was a few feet higher, in order to force a portion of the water to pass through the _specus_ before the rest fell over the cascade. There are ruins of the _piscinæ_ on the bank where the _specus_ began, and of the villa of Trajan on both sides of the loch, with the well-known brickwork and _Opus Reticulatum_ as facings for the walls. These magnificent cascades still remain, being a natural formation; but as the bed of the river is very deep, they are much concealed by the banks, and the shrubs upon them. The great walls or dams of Nero and Trajan being brought out to the edge, the cascades falling over them must have had a much finer effect, although the natural site is extremely grand and most picturesque; in fact it is celebrated among all the landscape painters of Italy, the scenery about Subiaco being among the finest of its kind of river and mountain scenery that is known. The enormous reservoirs or lakes, or lochs of Caligula and Claudius (commonly called of Nero), cover the space between the natural cascade and the outer wall of rock artificially constructed, over which the water was

made to fall. When the ignorant monks in the fourteenth century made an aperture in the great wall or dam, the force of the water soon enlarged it, and washed the whole structure away, leaving the great masses of stone or rock, of which it had been built, scattered in the stream below as if they were natural rocks, where they still remain. The object of the monks was to release their fields adjoining to the monastery above the falls from a temporary flood.

The _specus_ is nearly six feet high, and only sixteen inches wide; the men must have cut it standing sideways. There are apertures into it at intervals now open, and there probably always were such openings for the use of the _aquarii_ to keep the course clear. The _specus_ which Frontinus calls _subterraneus_, although that is _literally_ true, does not mean exactly what we now call a tunnel; but this _specus_ is cut in the rock of the cliff, with a few feet of stone only as an outer wall to it, and in this manner it is continued along the edge of the valley of the river Anio for many miles, always on the left side of the river in going towards Rome. An old road runs by the side of it, not now used for carriages, but remaining as a cart-road only; this must be the Via Sublacensis of Frontinus. Another road runs along the right-hand side of the valley, and is the one now in use: this is the Via Sublacensis Neroniana of the time of the Empire. The valley varies in width very much, in some parts it is three or four miles wide; this is the case where the springs of the Marcia and the Cerulean Lake gush out from the rock under the _diverticulum_ of the Via Valeria or present carriage-road, on the right-hand side of the valley.

The lowest of the three lakes of Claudius above Subiaco was circular, the rock being cut away to a half circle on each side of the stream; into this great basin the grand cascade fell from the second lake. The lowest lake or loch was comparatively not very deep. It seems most probable that the lowest reservoir was intended to serve for the Aqua Claudia. The _specus_ has not at present been traced quite so far; but it is found a little lower down, above the modern paper-mill. This is more than a hundred feet below the level of the Anio Novus. It may be that this was one of the springs that fell into the Anio, and was intercepted for the aqueduct. It is probable that the same was the case with the Anio Vetus, as we know it was with the Marcia; but as the water from the springs sometimes ran short in dry seasons, the Anio Novus was taken from the river itself, a part of which was turned into it from the great lake or loch. For this reason that water was always more abundant than all the rest, and was used to supply the deficiency in case of need, as Frontinus tells us. This _specus_ can be entered and examined; it is here a tunnel made in a rock of soft stone, with fissures filled with clay. The _specus_ is lined with brick, and covered with large flat tiles, placed at an angle, so as to form a roof sloping down to the two sides from the ridge in the middle. There are inscriptions recording repairs by Cardinal Barberini, nephew of Urban VIII. This _specus_ is that of the Anio Novus, constructed by Claudius; that of Trajan is about half-a-mile above the town of Subiaco, and on the right-hand side of the river Anio, not on the left, as the Anio Novus is.

The thirty-eighth milestone on the Via Sublacensis was found by Fabretti _in situ_, and the thirty-eighth milestone in the Via Valeria, now at Arsoli, is said by Gruter[136] to have been formerly at _La Sonnoletta_, or _ad fontem Somnulæ_: so that the two sources of the Claudian water, called Cæruleus and Curtius, were at the lake now called S. Lucia, in the territory of Arsoli; and the source called Albudinus is the _first_ of the four springs now called _Acque Serene_, while the other springs of the same name formed the _Aqua Marcia_.

The _Piscina Limaria_, referred to by Frontinus as erected by Claudius for filtering the stream, at the entrance of the Anio Novus, at the forty-_second_ mile[137] on the Via Sublacensis, is visible at the _Parata della Cartiera_ of Subiaco. This _piscina_ is not covered over, but open at the top, and is excavated in the rock of the bed of the river Anio, with a great declivity and with four cascades to throw down the sand, wood, and weeds brought down the river, and so to purify the water; but as it was still liable to become muddy in the time of floods, Trajan, according to Frontinus, excavated another _specus_ in the rock of the mountain near the Ponte di S. Mauro, where the great wall of the lake was situated[138].

The _specus_ of the Claudia seems to have been carried on the right-hand side of the valley as far as Vicovaro, about half-way to Tivoli, and then across the valley on an arcade, and carried on under the Anio Novus, and above the Marcia and Anio Vetus. All of these seem to be at different elevations on the side of the hill to the left of the valley, until they arrive at another valley crossing this, called the Valley of the Arches, about two miles from Tivoli, where they were carried across upon arcades. On these ancient arcades, or out of the materials of them, modern bridges have been made, both at Vicovaro and in the Valley of the Arches. The ruins of these splendid arcades are among the finest and most picturesque ruins of the Roman empire.

After passing the bridges across the valley of the Anio, the Anio Novus, Marcia, and Anio Vetus are continued along the side of the hill in what may still be called the cliff of the valley of the Anio, to _near_ the cascades at Tivoli, at different levels, the Anio Novus considerably higher than the others. To avoid the cascades here the aqueducts wind round the end of the hill. In going out of Tivoli to the promenade of Carciano, on the side towards Rome, there is a large college of the Jesuits on the left hand, the _specus_ of

the Anio Novus passing under this, and through a wine-cellar. About a quarter of a mile out of the town, two _specus_ are visible on the side of the hill above the road or promenade, and these may be traced at short intervals for miles, with openings into them in several places. The lower one is the Marcian, passing in a more direct line, and further from Tivoli, and is generally cut in the rock as a tunnel; the upper one is the Anio Novus, and is in some places faced with brick or with _Opus Reticulatum_, where it has to cross an opening. The Aqua Marcia here passes at a lower level below the road, with reservoirs at intervals, as already described.

At about three miles below Tivoli, and half-a-mile after passing one of the great reservoirs of the Marcia at the lower level, the Anio Novus is carried on an arcade across a valley and a small stream, at a place called after the arcade Arcinelli. The great Villa of Hadrian is nearly under this at the foot of the hill, perhaps a mile lower down. This was supplied with water by branches from the aqueducts, but without interfering with the main streams, which went on at the high level still at least five hundred feet above the level of Rome. From this high level the aqueducts led gradually down in a serpentine course, crossing several narrow valleys or gullies through the hills, along which some mountain-stream flows far below. At two important points, the aqueducts have to be carried across such valleys or gullies on fine arcades or bridges. The one nearest to Tivoli is called the bridge of S. Antony, from a small chapel made in the Middle Ages, probably in the fourteenth century, out of a portion of the _specus_ of the Marcia, in one of the chambers of a _castellum aquæ_ belonging to it, the rest of which has been destroyed. The _specus_ of the Anio Vetus under it has also been destroyed, but the arcade is preserved for the use of horses and foot-passengers. This bridge is about eight miles from Tivoli. There is no carriage-road to it, but a tolerable path for horses or donkeys; it is one of the finest and most picturesque objects on the whole line of the Aqueducts, and is about 100 ft. above the water in the stream below which is called the _fosse_ of S. Antony. This valley or gorge in the mountain, with the bridge across it, is not easily seen from any distance; but the site may be indicated by a medieval castle with a tall square brick tower, which is a conspicuous object for miles. This is distinctly seen from the bridge, and as it stands at the mouth of the valley, that object must be seen from thence on looking up the valley. This bridge is a really grand work; it is 373 ft. long, 16 ft. wide, and about 104 English feet high. The dome of S. Peter's at Rome is visible at a long distance from the hill above the medieval castle.

Following the direction of the aqueducts towards Rome for about a mile, along a very rough cross-country path, we arrive at a good carriage-road from Rome to Poli, and about a mile beyond that is another magnificent structure, as fine and more perfect than the last, called Ponte Lupo, one of the greatest works of all the Roman aqueducts. There are not so many open arches as at the bridge of S. Antony, but a greater extent of substructure and wall at each end, and the height above the mountain-stream is even greater. Several of the arches seem to have been filled up for greater strength, at an early period; it is all work of the first century. Here the two _specus_ of the Claudian and the Anio Novus are perfect, one upon the other, and serve as a lofty parapet to the road for horses, which passes across the valley along the side of them, the _specus_ occupying about one-third of the width of the bridge. The two _specus_ seem to have been first brought together at this point, and afterwards continue one upon the other for the rest of their course into Rome, interrupted only by the _piscinæ_ and _castella aquarum_ at intervals.

There are ruins of another arcade across the valley at a lower level by the side of this grand bridge, only a few yards from it, which can only be that of the Marcia. The Anio Vetus appears to be carried across under the Claudia and Anio Novus at a much lower level, and it is probably for this reason that the arches are closed instead of being left open. They pass upon four other bridges over the streams of S. Gregory and of the Inferno, before they arrive at the _piscinæ_. They all four meet at this point, and then diverge again for miles. This splendid work is about ten miles from Tivoli, half-a-mile from the carriage-road, five or six miles from the Villa of Hadrian, and out of the line of the direct road to Rome, but very near the road from Rome to Poli. After passing these great works, the aqueducts are continued at their respective levels in the direction of La Colonna and of the _piscinæ_, and are carried in tunnels through the hill, but these tunnels do not appear to be of any great length; they merely pass through part of one side of the hill. They bring us to the _piscinæ_, which are about six miles from Rome, where the arcades begin, and from this point the Marrana follows the same direction in the bed of the Almo, winding about but never very distant from the arcades, and always receiving the surplus water. This stream is here divided into two branches, one of which goes through Rome and into the Tiber at the Pulchrum Littus; the other passes through the valley of the Caffarella, and falls into the Tiber near the church of S. Paul beyond the walls, as is explained under the head of the Aqua Crabra and the Marrana.

The _specus_ of the Anio Novus is always faced with brick or with _Opus Reticulatum_; it is carried _upon_ the Claudian arcade, and the one _specus_ always rests upon the other: what applies to one applies to both after the first junction. The aqueduct of Claudius has a stone _specus_ carried on a stone arcade for the last five miles into the city. It was begun by Caligula, and carried on by his successor; this portion was completed in fourteen years, a very short period for so enormous an undertaking. The Anio Novus was the most abundant of all the aqueducts, as stated by Frontinus[139].

The arches of aqueducts, stretching for miles across the open country and entering Rome at the eastern angle, are the first objects to attract the attention of strangers on approaching the city. These are the arches of the Claudian aqueduct, built of large square stones, with the angles chamfered off, and carrying the streams of the Aqua Claudia and of the Anio Novus.

Of the _Piscinæ_ mentioned by Frontinus, the ruins of one remain at the place now called Porta Furba, where the aqueducts just mentioned meet again about two miles from the city. The lofty Claudian arcade passes over the Marcian arcade at this point, at one of the numerous angles, as it had previously done at the Torre Fiscale. From the Porta Furba to Rome, the Aqua Felice is carried against the side of the Claudian, or on the piers of the Marcian, as most convenient, frequently crossing from one to the other on arches over the road. The _specus_ of the Felice is built in the roughest manner of old materials taken from the other two arcades. The Anio Vetus also passes underground at the Porta Furba. Immediately after the entrance of the Claudian _specus_ into Rome at the extreme east end, in the gardens of the Sessorian Palace (now S. Croce), there are remains of at least four reservoirs or _castella aquarum_ before it reaches the Porta Maggiore[140].

Nero was the immediate successor of Claudius, A.D. 54-69, and carried on the conduit into the city, on what are still called the arches of Nero, which are faced entirely with brick, and some of the most beautiful brickwork in the world. So gigantic a work as these aqueducts could not have been completed in the lifetime of a single emperor, however large the number of slaves he may have employed upon it.

THE NERONIAN ARCADE.

The arcade of Caligula and Claudius, which is entirely of stone, terminates at the Porta Maggiore, the Esquilina of Frontinus. The work of Nero includes the arches within the city from the wall close to the Porta Maggiore to the great _castellum_ on the Cœlian, over the arch of Dolabella. The _specus_ of the Anio Novus is easily distinguished from the _specus_ of the Claudia, as the latter is of squared stone.

The arcade of the Claudia has been considerably repaired with brick, and the arches filled up in several places with brickwork of the time of Septimius Severus and Caracalla, A.D. 193-217. This may be distinctly seen in that part of the arcade which is between two and three miles from the city, near the Porta Furba. It was again repaired by Pope Hadrian I. in 780, and several times by other Popes.

The remains of these two aqueducts, one above the other, are admirably seen in their course along the top of the Porta Maggiore; and at this spot their relative levels with regard to the Marcia, Tepula, and Julia, are also clearly exhibited, the latter entering the wall close to the gate, and almost at right angles to it. Thus, at one view, we are able to see the _specus_ of five out of the nine aqueducts, mentioned by Frontinus, actually remaining. A sixth, the Anio Vetus, also passes under the Walls of Rome at the same point; the _specus_ is half underground, and now concealed by the _restorations_ made in 1869.

An inscription upon the face of the _specus_ itself in the wall of the city over the archway, records that Claudius the son of Drusus, caused to be brought into the city the water of the Claudian conduit, from the springs called Cæruleus and Curtius, from 45 miles distance; also the water of the Anio Novus, from 62 miles, at his own expense[141]. These dates here given correspond with the year 798 of Rome, or A.D. 45. Great repairs were made by Vespasian and Titus to the Claudian aqueduct. The distance from which the Anio Novus is brought, according to this inscription[142], is 62 miles, which agrees with Frontinus[143].

The architect of the Claudian is believed to have been Claudius Annius Bassus, mentioned by Tacitus as chief engineer at Carthage under Marcus Silanus, the father-in-law of Caligula. The remains of the tomb of Bassus may be seen near Vicovaro. The tomb of another architect and his family, on the side of the _agger_ upon which the arcade of Nero stands, near the Porta Maggiore, was excavated in 1865. From its situation immediately under the _Neronian Arcade_ against the bank on which it stands, there seems no doubt that this Tiberius Claudius Vitalis, whose name is inserted on the front of the tomb, was the architect of the arcade; and it does infinite credit to him, for it is one of the finest pieces of brickwork in the world.

This arcade, commonly called the Arches of Nero, carried the _specus_ of the Claudia[144] and Anio Novus combined. It first crosses the foss on a double arcade, one upon the other, to give more height across this wide and deep inner trench; it is then carried on a high bank, and therefore on a single arcade only to the Lateran, and on another bank across the foss between the Lateran and the City to the Cœlian, and along the north side of S. Stefano Rotondo to the reservoir and _piscina_ over the arch of Dolabella. This arch was the principal entrance to that part of the Cœlian in which the _Claudium_, or courts and temple of Claudius, were situated. There are magnificent ruins of a large _castellum aquæ_ over this arch, faced with the beautiful brickwork

of Nero; in part of this the small church of S. Thomas in Formis has been made.

Another large subterranean reservoir remains perfect on the west side of this lofty brick _castellum_ of Nero. This consists of three large vaulted chambers under the garden between the church of the twelfth century and the small monastery of the Redemptorists, now (1872) all belonging to the Villa Mattei, or Celimontana. There is, through the crown of each of the vaults, a circular opening, or well, closed by a stone, which can be moved at pleasure for letting down buckets into the water; it is still used for the purpose of irrigation. From the low level of this reservoir, it must have belonged to the Aqua Appia. By the side of the garden over this, and above ground, in a line with the Arch of Dolabella, is a wall of the first century, faced with reticulated masonry, probably part of the _castellum_ of that period, as new reservoirs have been built there for each successive aqueduct that came to this point. The highest, being that of Nero, was 50 feet above the level of the ground.

Thence the water was distributed in different directions, one branch to the Claudium[145], and thence again to the _stagnum_ or pool originally of Nero, but afterwards retained under the Colosseum; a second to the Palatine, passing down the western side of the Clivus Scauri opposite to the church of SS. John and Paul. Then, after making one of the usual angles, it was carried across the valley on the arches attributed to Nero, but in this part really after his time, the lower portions of some of which remain. The third branch was to the Aventine. The plan for this was not carried out until the time of Trajan, when a lofty arcade was made across the valley from the Cœlian to the Aventine, passing over the Porta Capena above the Aqua Appia, which had previously been made in the same line, and with new reservoirs for it, generally by the side of the old subterranean ones. One great reservoir under the Cœlian occupies a considerable part of the space between the cliff and the present road, and is now turned into a gardener's house. The excavations made there in 1868 have been described in the account of the Appia; the piers of the tall brick arcade of Trajan remain on both sides of the road leading direct to the north end of the ruins of the Piscina Publica, on the other side of the Marrana, under S. Balbina; the upper part of this great building is of the time of Trajan. On the side of the Cœlian are remains of another large _castellum_, of two stories, of the same period. There are also remains of this aqueduct on the brow of the Aventine Hill, near the church of S. Prisca, in front of the monastery, now in a vineyard opposite to the Palatine, and overlooking the Circus Maximus.

The water both of the Anio Vetus and of the Anio Novus was of inferior quality, and was used chiefly for watering gardens, and for the more common purposes in the city; the Anio Novus, being higher than any of the others, and the water very abundant, assisted all the rest. Trajan endeavoured to improve the quality of the water by excluding the more turbid sources, and using only the most pure, as we learn from Frontinus, who was the person charged with the execution of the work[146]; and this inscription was put up, IMPERATOR CAESAR NERVA TRAJANVS AVGVSTVS.

The waters of the Claudian and Anio Novus are stated by Frontinus[147] to have been united after their entrance into the city, and then distributed to all the fourteen Regiones. Several subdivisions must therefore have been made at different points, and, wherever a division or a junction took place, a _castellum aquæ_ was required. The union of the two streams was probably made in the large reservoir at the angle of the Sessorian gardens and City wall near the Porta Maggiore. Another great division was over the Arch of Dolabella; one branch was afterwards carried on by Domitian to the Palatine upon the lofty arches, some of which still remain, and into his reservoir at the south-west corner of the Palatine Hill, part of the baths or _thermæ_ of his palace. The branch over the Via Appia to the Piscina Publica and the Aventine was not made until the time of Trajan and Hadrian. A great deal of work was done to the aqueducts at that period. The amazement of the people at seeing copious streams of water pouring over the arid heights and slopes of the Aventine, is recorded by a contemporary author. This was the branch of which a portion remains near Santa Prisca. The branch from the Palatine to the Capitol, of which two of the tall piers remain[148], was made by Caligula; this is sometimes called a bridge across the Forum. To convey the water to the other Regiones, the older conduits or _specus_ were probably used.

In the fourth century, there were great complaints of the stealing of the Aqua Claudia by the farmers through whose lands it passed, and several strenuous decrees against this practice were issued by the Emperors Arcadius and Honorius, A.D. 400. Similar edicts were issued repeatedly by these Emperors, and by Constantine[149].

The springs called Cæruleus and Curtius, to which (when united in this aqueduct) the name of Claudia[150] was given, as Frontinus tells us, are situated in a valley on the south side of the river Anio, thirty-eight miles from Rome, and eight miles below Subiaco (which is forty-six miles from Rome), and not more than half a mile from the source of the Marcia. Several streams issue from the rock under the present carriage-road, a _diverticulum_ or branch of the ancient Via Valeria, and form a beautiful small lake of very clear water having a distinctly bluish tint. Another of these springs, the Albudinus, is still considered as equally good with the

Marcia, or nearly so. The Anio here flows at the opposite end of this small valley, and both the lakes are now emptied into it. This valley is in the territory of Arsoli, so called from a neighbouring village on a height overlooking it, and the lake of S. Lucia. The spring called Curtius is another of these streams.

This valley is admirably calculated for the sources of aqueducts; the ground is full of springs of beautiful water, and the watery meadows have only to be dammed up a little to form lakes or reservoirs. Probably the water from these springs, which now runs into the river, was entirely intercepted and carried into Rome in the aqueducts. The Anio is in general such an abundant stream, that these additional springs would scarcely be missed, although in time of severe drought the water did sometimes run short[151].

The _piscinæ_, mentioned by Frontinus, were large subterranean reservoirs and filtering-places, at seven miles from the old City or from the inner gates, and six from the outer gates: the portion of Rome outside of the walls of _the city_ was considered as the suburbs only, until the time of Aurelian, when the City was made to extend to the outer wall, then newly raised and fortified, but this was long after the aqueducts were made. The present appearance of these two _piscinæ_ of the Claudia and the Anio Novus is merely that of earthen mounds or tumuli. They are situated about midway between the old Via Latina, which now in this part is made into a carriage-road to Frascati, and the Via Appia Nova. The distance from one road to the other is about a mile, and the _piscinæ_ are about half-a-mile from each. The stream, which was originally a branch of the Almo, and now conveys the water of the Marrana and the Aqua Crabra united, runs near them, and received the surplus water from all the aqueducts on this line. It is divided into two parts near the _piscinæ_, one branch going through the valley called the Caffarella, and falling into the Tiber near the church of S. Paul's outside of the walls; the other keeps near the arcades and reservoirs, and coming through Rome, passes on the south side of the Cœlian. This branch had come from the _piscinæ_ nearly parallel to the aqueducts; it winds about a good deal, but is never distant from the line of the latter, now on one side and then on the other. A further account of this will be found under the head of the Marrana, in the second part of this chapter.

APPENDIX TO CHAPTER IV. PART I.

THE NINE AQUEDUCTS IN THE TIME OF FRONTINUS.

Having sketched the general history of each one of these aqueducts, and the circumstances under which they were erected, it remains to refer briefly to some of those details which Frontinus has handed down to us, of the mode of management of the water. These details apply equally to the whole series. First of all, the position which he and his predecessors in office held was a very important and honourable one. He had the entire responsibility of the water supply, and the absolute control of seven hundred men employed to attend to their proper working, to clean the _piscinæ_, and to repair the channels and pipes when needed. Of these, 240 were appointed by the City, and the remaining 460 by the Emperor. The channels in which the main stream of water was carried, and the reservoirs (_castella_), and the _piscinæ_, were always lined with a particular kind of cement, called _Opus Signinum_.

It has also been observed that the base of the channel is constantly broken up by inequalities, or dips, if they may be termed so, as if purposely introduced to agitate the water in its course, and, consequently, to aërate it. No doubt also the inequalities, provided they were rugged, would tend to check the passage of any earthen matter held in solution by the water. Of most importance, however, and shewing still more remarkably the engineering qualities of the builders of the Aqueducts, were the ventilating-shafts which were introduced at proper intervals. Such shafts were often used as wells also, to let buckets down for water, and steps were cut on the sides for the _aquarii_ to descend and remove obstructions. At about every half-mile the _specus_ forms an angle to break the force of the water, and at such points there is usually a reservoir also. Advantage was taken of these angles for the later aqueducts to be carried over the older ones, as at the Torre Fiscale and the Porta Maggiore. These precautions, combined with the system of _Piscinæ_, rendered the water constantly fresh, pure, and wholesome.

From some considerable remains of the _Piscinæ_, the system can be clearly made out. The building consisted of four chambers, two beneath and two above. Supposing, for the sake of illustration, in the annexed diagram, the letters [Illustration: A B C D] represent the four chambers. The channel of the aqueduct, coming at a tolerably high level, enters the chamber A. Thence the water passed (possibly over a large waste-pipe) into the chamber beneath, B. Between B. and C. there were small holes communicating through the wall (possibly provided with fine grating). Through the roof of C. there was a hole, and the water passed upwards, of course finding the same level in D. at its exit, as in A. at its entrance; on leaving the _piscina_ the water was carried off into another _specus_. By the aid of sluice-gates the water could be transferred direct from chamber A. to chamber D. Access was obtained by an opening to the chambers beneath, and the mud was from time to time cleaned out. Curious details of the sluices,

&c., have been found; but it is not easy to determine their age, as the aqueducts have undergone so many repeated alterations.

As a typical example of the size of the _specus_, or channel of the Aqueducts, the Marcian may be taken, which measures in the opening five Roman feet in height, two and a-half in breadth, and the thickness of the wall on each of the two sides one foot. The roof of the Marcian being surmounted by the Tepulan and Julian, no great solidity was needed; but so far as can be ascertained, the roofs were generally of considerable thickness, to prevent, as much as possible, the heat of the sun spoiling the coolness of the water. The channels and general structure of the Anio Novus and Claudian were larger in every respect, those of the Tepulan and Julian somewhat smaller, as shewn by the accompanying diagrams.

It will be seen that the period of the construction of the nine aqueducts which have been described, embraces some four centuries, as Frontinus was employed in surveying them towards the close of the first century after Christ, and the first aqueduct was commenced more than three centuries before the Christian era. If we omit the Alsietina, which was on the other side of the river, and which ought scarcely therefore to be taken into account, the order of level follows almost exactly the order of construction, the only exception being that of the Virgo. This increase of height of level as each new aqueduct was added, is pointed out by Frontinus in his eighteenth chapter.

It will be perhaps convenient to have the several aqueducts already described represented in a tabular form, shewing the dates when they were made, and the order as to level, together with the distances which they traversed.

The aqueducts, especially those which were mostly underground, it will be observed, made long detours, as compared with the direct line of road; as, for instance, in the first on the list, the distance by road was but eight Roman miles, but that by the channel of the aqueduct was eleven miles. The total length of all the channels of the aqueducts, constructed in less than four centuries, was upwards of 285.610 Roman miles, of which 242.697 miles were cut beneath the surface, and 42.918 miles carried on substructure, arched or not, as the case required, above the surface of the ground.

| LENGTH OF CHANNEL.[152] Order as | Above Under DATE. No. to Level. Of the above, six are carried to Piscinæ on the Via Latina.

{ V. JULIA } The three { IV. TEPULA } carried from the same reservoir { III. MARCIA } on the same series of arches.

The two { IX. Anio Novus } carried on higher arches, which end { VIII. Aqua Claudia } after the Pallantian gardens.

The one II. Anio Vetus, has a reservoir on the Via Latina.—(_Fron._, c. 19.)

Buecheler, in his edition of Frontinus, pp. xi., xii., xiii., explains the mathematical part of chap. 78 differently from Poleni and Dederich[153].

In order to regulate these several aqueducts, so that deflection in any part should be easily ascertained, means were provided for estimating the abundance of the water, and in this respect for its minuteness and clearness the treatise of Frontinus stands unrivalled, when compared with any work of ancient or even modern times. The mode of measurement is to take the area of a vertical section of the water flowing along the _specus_,—the object being to test each aqueduct by itself, and to see whether its proper supply was given or not. Had he been called upon to estimate the actual supply of the water, and not the relative, other points would have had to be taken into account, namely, the average fall of the aqueduct, from which to gather its velocity. On this, however, he does not touch. It must be borne in mind, also, that when Frontinus was appointed, the system had been long in force, and he had to follow the traditions and rules of his office. He made no revolution, he was simply a reformer. He tells us that in examining the books belonging to the office, he found certain measures given to certain aqueducts; these he had to verify, and a great part of his work is taken up in the account of his operations. To begin with, he is much troubled as to the measures employed. The _digitorum modulus_ (i.e. a pipe with a given measured orifice) is uncertain. There is the square digit and the round digit (in other words, a square pipe of which each side is one digit, and the round pipe of which the _diameter_ is one digit). As an instance of his accurate and clear expression, it may be worth while to quote his words on this point[154]:—

“The measurement of the _Moduli_ is taken either by digits or inches. In Campania and in many places in Italy, the digit is used; in Apulia, the inch[155]. The digit, as all agree, is the sixteenth part of a foot; the inch, a twelfth part. But just as there is a different usage of inches and digits, so also there is no uniformity in the simple computation of the digit itself. There is one which is called the square digit, another the round digit. The square digit is _three-fourteenths greater_ than the round; the round is _three-elevenths smaller_ than the square, because the angles are taken off.”

In this we obtain a key to most of his calculations[156], because they depend throughout upon the computation of the area of the circle.

The base measure chosen was the “quinary,” so called (according to the most natural derivation) because its diameter was five quarter-digits. And to this basis are reduced some twenty different _moduli_, to which the names were given of senary, septenary, octonary, denary, duodenary, and so on up to centenary. The reduction of these seems to be tolerably accurate according to the system which he pursues, and making allowance for transcribers’ errors. But either the relation of the circumference to the diameter of a circle had not been worked out to the same extent to which it has been in later times, or Frontinus considered the ratio adopted sufficient for his purpose. One of his calculations stands thus: he is measuring the Appian at a point where it is joined by a later branch; it had been assigned in the register as giving 841 quinaries: he says—

“I found the depth of the water five feet, and its breadth one foot and three quarters, which gives an area of eight feet and three quarters. This is equal to twenty-two _centenaries_ and a _quadragenary_, which make 1,825 _quinaries_, or 984 quinaries more than is given in the Commentaries[157].”

Each centenary is shewn elsewhere to contain 81 quinaries and a fraction, and therefore 22 would give 1,792 in quinaries and a fraction. The quadragenary is marked to contain 32 quinaries and a fraction. Together, therefore, the 1,825. Now the area of each quinary, according to the system of Frontinus, would be the square of its diameter (i.e. 1¼ digit), multiplied by ¹¹⁄■■ (the ratio already ascertained). This equals ²■■/■■■, which, multiplied by 1,825, produces 2,240½ digits (nearly). Finally, the area of 8¾ square feet, reduced to square digits, gives 2,240[158].

This calculation illustrates his mode of computation from absolute measure of the water; but the ordinary way was to affix the _moduli_, which were of brass, or rather of bronze, to certain openings. Provided the _modulus_ was placed perfectly level, the water flowed at its ordinary rate; and when the _moduli_ were sufficient to prevent the water rising in the reservoir or channel, and, on the other hand, not too numerous or too large to reduce the mean level of the water, the sum of them represented the amount of water.

We next come to the question of distribution. On examining the registers, Frontinus says that he found that there were assigned to the nine aqueducts 12,755 quinaries; but it appeared that the distribution amounted to 13,470 quinaries. To account for this discrepancy, the whole were re-measured. In the annexed table the measures of each aqueduct are given separately, and by adding together the results of each, as calculated from the data which Frontinus gives of the water measured at the head, the total, as the table shews, comes to 24,413 quinaries. The fact was that in process of time some of the channels had fallen into decay, and the water was wasted. In other and more numerous cases, it had been abstracted by persons for their own use without authority; in addition to which there were no doubt errors in the computation, which had crept into the books, and if we are to believe Frontinus, these errors had been turned to the profit of his predecessors.

In the table of distribution will be seen the number of quinaries distributed outside the wall of the city; next, the Regiones which they serve within the city; thirdly, the measure of water so distributed within the city, and the number of _castella_, or reservoirs, used for that purpose. These reservoirs, at least such as remain, will be described in the several Regiones in which they occur. That over the arch of Dolabella on the Cœlian Hill, and the so-called Castellum Aquæ Juliæ on the Esquiline, are the most prominent. Many, no doubt, were of much smaller size, and merely large cisterns, as the total number was 247.

The supply of 13,470 quinaries is thus accounted for. Outside Rome 3,164 quinaries were distributed, inside 10,306; of that outside Rome 1,718 quinaries were used “in the name of the Emperor,” that is, to supply the imperial villas and gardens, &c., while 2,345 were charged to private persons. Inside Rome 1,707 were charged to the Emperor for his palaces, &c., while private persons used 3,847 quinaries, leaving 4,401 quinaries, which were for the “Public Service.” These, together, account for the 9,955 distributed within Rome.

In the details of the distribution, we learn how much water was employed in the palaces, &c., in the service of the Emperor and his household (_nomine Cæsaris_), how much was carried into houses for the use of private persons, and how much was used in public buildings and the public reservoirs or fountains which were established in all convenient positions, and generally accessible to the population.

It may, perhaps, be interesting to examine more carefully the distribution for the “Public Service.” We have four classes of recipients, and we know from Frontinus how much was served to each class from each aqueduct. There were first of all 19 _castra_ or barracks, in which the army were kept when not out on service, and in which also the guards were stationed. These required in all 279 quinaries. There were next, 95 different Public Establishments which used 2,401 quinaries, and 39 theatres and places of entertainment (_munera_) which used 386 more. Lastly, there were 591 open reservoirs (_lacus_) for the service of all comers, using 1,335 quinaries. These reservoirs were what we usually speak of as fountains, and some hundreds are in use to this day, many probably on the site of the older ones. There were very stringent laws respecting their use. Heavy penalties were inflicted upon anyone dipping a dirty bucket or other vessel into the reservoir; there were also laws respecting the “overflow,” as the fountains of course were constantly running. These were the most important to keep in order, as all the poorer classes depended entirely upon them for their supply of water.

The more wealthy had water brought into their own private reservoir in the court, with buckets and windlasses for drawing the water to the upper story, and this is the case to the present day[159].

These details, while giving us an insight into the social state of the city, go to shew how thoroughly the supply of the water was under control. The pipes supplying every one of these 744 points of distribution were all registered, and their sizes being known, the system of computation, as explained by Frontinus, was brought into play: thus every part was checked, and any irregularity could be traced to its source.

It may be asked what amount of supply, in gallons, would the water represent, in order that a comparison can be made between the supply of towns at the present time, and that of Rome at the time at which Frontinus wrote. The answer is not easy. As said before, we have not sufficient data for an accurate determination; still we may attempt an approximate estimate. It is easy to compute the section of water given by the 24,805 quinaries. This being just upon 120 square feet, we can form some notion of the vast quantity,

if we picture to ourselves a stream twenty feet wide by six feet deep, constantly pouring into Rome at a fall six times as rapid as that of the river Thames. It has been computed by a French engineer that, together with one or two additional aqueducts which were added between the time of Trajan and Aurelian, the supply of water to Rome was 332,306,624 gallons _daily_. If we assume the population to have been a million souls—and it is scarcely probable that there were more—we find that the rate was 332 gallons per diem for each person. In our own day we consider 40 gallons sufficient, and many think this excessive, including the use of water in manufactures, &c. No wonder, with the facilities for drainage which the rapid Tiber afforded, and with this plentiful supply of really good water, the great city was rendered, in spite of overcrowding and an unhealthy situation as regards its neighbourhood, comparatively free from those epidemics which are so fatal in all densely-populated towns.

One part of the system which Frontinus seems to have been the first to adopt was this: he had 247 _castella_, or main reservoirs, from which the pipes were carried to the smaller cisterns and fountains, and he so arranged the supply of water to these that the several aqueducts could be interchanged. A net-work was established, so that when one channel, from whatever cause, failed, whether from requiring to be cleansed or repaired, another could supply its place. But this was not all. He tells us, cap. 87, that many of the parts of the city which were dependent on one source for their supply, were, by careful distribution of the water, able to avail themselves of a second in case of need; and he gives as an instance that the Marcian was made available in the Aventine, by being carried across from the Cœlian[160]. He also speaks of the improvements which were made in keeping the water pure. Hitherto a very slight shower had made many of the streams muddy, although at their source they were pure[161].

The least pure, however, before the time of Trajan, were the Anio Vetus and Anio Novus. This arose from the banks which, being soft, gave way, and the stream, even in fair weather, thus became muddy. He points out that hitherto, by the mixture of the waters which had been adopted to prevent failure in supply, proper skill had not been shewn, and these new streams were allowed to destroy the purity of others[162]. His object, therefore, was to keep the pure streams separate, and in addition to that, arrange that they should be used for drinking purposes only; while the water which was less grateful to the taste, and which was subject to be at times muddy, should be used for cleansing the city, or watering the gardens, or other ordinary purposes, which it might fulfil equally with the fresher and purer water. In considering the supply of water to our large towns, which is one of the great problems which at the present time has to be solved, it is not too much to say that—the plan adopted by the Emperor Trajan, by the advice of Frontinus, the head of the _aquarii_, and of that department of the government of Rome which had charge of the aqueducts, the importance of which in that climate can hardly be over-estimated—is worthy of more attention than it has received[163].

THE CURATOR AQUARUM.

The care of the aqueducts was assigned by Augustus to a Curator Aquarum, of whom Marcus Agrippa was the first, and held the office for life. Frontinus, to whom we are indebted (as we have seen) for nearly all that we know respecting the early history of the aqueducts, held this office under Domitian, A.D. 94; he remained in office under Nerva, wrote his treatise at that time, and died under Trajan, A.D. 107. The office continued to exist till the third century, in the time of Diocletian, when it was superseded by the magistrates called _Consulares Aquarum_, a title changed in the fifth century into _Comes Formarum Urbis_. These several magistrates had 700 servants, charged with the superintendence, repair, and distribution of the water from the aqueducts, divided into _familia publica_ and _familia Cæsaris_; the former, comprising 240 persons paid by the State; the latter, 460 paid by the Emperor. Agrippa supplied the city with 700 _lacus_, 105 fountains, 130 _castella_ for distributing waters, and 170 gratuitous baths for public use. These structures were adorned with 400 marble columns, and 300 statues of marble or bronze. After the devastations caused in the Gothic wars, under Vitiges and Totila, only the most important aqueducts were restored, either by Belisarius or Narses. Ruin and neglect again undid much of what had then been restored to use. At the beginning of the ninth century, the only aqueducts supplying water were the Appian [I.], and Marcian [XII.], then called Jobia or Iopia, by corruption from “Jovius,” the name assumed by Diocletian.

During both the eighth and ninth centuries, indeed, various repairs for maintaining the aqueduct of Trajan [X.], which carried water from the lake Sabatinus (di Bracciano, Acqua Paola), are mentioned by Anastasius; and in 786 the “Jovia” aqueduct was restored by Hadrian I. In the twelfth century, the Aqua Lateranensis is mentioned as still in use, being that part of the Claudian aqueduct carried upon the arcade called the Arches of Nero near the Lateran, where the _specus_ is very conspicuous. The aqueduct of Trajan [X.], and that of Agrippa [VI.], continued to supply water, though but scantily, for about two centuries later. The Appia [I.] has long been supposed to have been gradually stopped up by the deposit of clay, and thus rendered useless[164]; and so total was the failure of all these waters in the fourteenth century, that the population (said to have been not more than 17,000 during the absence of the Papal Court at Avignon) were without any supply of running water, except from the Tiber[165]. The first restoration,

in the fifteenth century, was that of Agrippa [VI.], by Nicholas V., whose aims and efforts were renewed by Sixtus IV., and by later Pontiffs. Sixtus V. [Felice Peretti] determined to restore to Rome the water then supposed to be the Marcia, but really of Hadrian [XIII.] The arcade of the Claudian [VIII.] and Anio Novus [IX.], was the most magnificent of all, and conveyed its several streams along a distance of forty-six miles. This had been restored by Vespasian and Titus, by Trajan, Septimius Severus and Constantine; but, in the greater part, especially within the first few miles from Rome, the existing stone arcade is of the time of Claudius, with repairs in the brickwork of the Flavian emperors. At the beginning of the ninth century, it was certainly still serviceable, and was known by the name Forma Claudiana. The piers of this arcade were used by the engineers of Felice to carry that _specus_ on the part near Rome; but the greater part of the Marcian arcade, and considerable parts of the Claudian, near Rome, were used as a stone-quarry by them. The channels through which the Anio and the other streams flowed, were the first, 9 ft. in height and nearly 3 in breadth, the second 6 ft. by 3, as seen in their ruins at the Porta Maggiore. The more ancient portion is not in brickwork, but of enormous squared blocks of tufa and peperino.

The popular notion that all these aqueducts were a mere waste of money, arising from the ignorance of the ancient Romans of the simple fact that water will rise to its level, is altogether erroneous. Vitruvius gives directions for taking the levels for carrying water through valleys, where, he says, there should be standing or upright pipes (_columnaria_,), now called respirators, to let off the confined air (_spiritus_[166]), and explains how to bring the water on by earthenware, lead, and even leather pipes.

Within the last few years a large leaden pipe of great antiquity, not less than two feet in diameter, was found under the Via de' Condotti, encased in ancient brickwork, evidently shewing that they were afraid to trust to the strength of the lead. The force of the water running in a strong current from such great distances, required to be broken at frequent intervals, by being turned at a sharp angle, and then allowed to return again to its course by another angle. This arrangement occurs continually along the line of the aqueducts, generally at each half mile, with a _piscina_ or a _castellum_, or both filtering-place and reservoir, at each of these angles. The great object of constructing these magnificent aqueducts was to bring the water to the highest levels in the city, from which it descended by a succession of reservoirs (_castella aquarum_), some with _piscinæ_ or filters, others with fountains, each one below the level of the preceding one. The lower town along the valley, or Campus Martius, was also supplied by other aqueducts at a much lower level. The ancient Romans had abundance of leaden pipes to convey the water to the baths or _thermæ_, and bronze stop-cocks, as may be seen at Pompeii, and silver ones for the emperor; but they had no pumps. From each _castellum_ there were pipes to supply the neighbouring baths or palaces, with moderate pressure; also wells or cisterns in the courtyard of each house, which had frequently a fountain. On the Janiculum, the water of the aqueduct passing from one _castellum_ to another, has sufficient force to turn several mill-wheels.

A letter of King Theodoric, printed in Cassiodorus[167], addressed to the Roman Senate, enjoins them to assist Joannes in his enquiries after those who have diverted the water from the aqueducts for their own uses, and those who have stolen the brass and lead, or those who have helped them. This proves that they were not destroyed by the Goths, and that they were in use in the sixth century.

CHAPTER IV., PART II.

THE LATER AQUEDUCTS.

X. SABATINA, A.D. 110; TRAJANA AND PAOLA, A.D. 1540.

The Aqua Sabatina came from the springs which supply the lake Sabatinus, now called di Bracciano (in the Middle Ages it was, and is still often called, Anguillara), on the side opposite to Rome, about twenty-four miles from the city, in a tunnel at a considerable depth. It arrives at the line of the tunnel of the Aqua Alsietina in about three miles. (See Aqueduct VII.)

The line of this aqueduct, which is chiefly subterranean, can be traced backwards by the respirators of Paul V., who repaired it, from his fountain on the Janiculum in Rome across Monte Mario to La Storta, and a little beyond it to the junction of the roads from Viterbo and Bracciano. Here the present road follows a winding course for the sake of better gradients, but the old one (_Clodia_) followed a more direct line in a cutting through the hill, to the left of the present road, as may be seen by the old paving-stones at intervals; and here, instead of the clumsy respirators of Paul V., are wells only, one of which is near the present road at the junction. The respirators are built over old wells, and serve to shew that Paul V. restored the _specus_ from La Storta to Rome only in this part. There are no respirators beyond that point for some distance, but the _specus_ may still be traced by the wells descending into it. About two miles further on, this _specus_ is carried on an arcade across a valley, and it may be traced from thence to the

point where Nibby explored it in 1826, near the lake of Bracciano. From the Osteria Nuova (fifteen miles from Rome) to La Storta (ten miles from Rome), the rough pyramids continue along the line of the aqueduct, and at the Osteria itself there are two of different dimensions close together at the end of the house or _castellum aquæ_; one is nearly double the size of the other, and both are of very rough construction. Probably one of these is of the time of Trajan, the other of the time of Pope Paul; these wells, with the smaller pyramids over them, are continued to near La Storta; here a change takes place, and the respirators are modern, as has been said.

Procopius expresses his amazement at the quantity of water thus brought to the top of the Janiculum, and poured in torrents over the whole of the region of the Trastevere. This is still the case, and the fountains in front of St. Peter's and in the gardens of the Vatican, are also supplied from this aqueduct. The water is so abundant that it is even brought over the bridge and supplies a fountain on the other side.

Paul V. also mentions (in his inscription at the fountain above S. Pietro in Montorio) that it had been previously restored by one of his predecessors, Hadrian I., A.D. 774. This was after it had been damaged by the Lombards under Astulfus, as recorded in the Pontifical Registers of Stephen III., Hadrian I., and Gregory IV., in whose time (A.D. 830) the work was completed. The Saracens again destroyed it in 846, and it was again restored by Nicholas I. (A.D. 860). It continued in use in the fifteenth century; but in the sixteenth it was much out of repair, and the branch to the Janiculum almost entirely failed. That to the Vatican continued to flow in 1561, and was repaired by Pius IV., as recorded on an inscription in the garden of the Vatican. In 1618, it had become almost entirely ruined, and was restored in a more thorough manner at great expense by Paul V., a member of the wealthy Borghese family, from whom it is now commonly called the Aqua Paola. The Orsini family, to whom the lake Bracciano belonged, contributed 2,000 ounces of water daily from that lake. Hadrian I., who had made the first great restoration of this water-course, was a Colonna, so that three of the greatest medieval families of Rome have contributed towards it.

The cascade which now falls down the face of the Janiculum, in a _specus_, turns the water-wheels of three mills in its course; this is mentioned by Procopius, they having been destroyed by the Goths, and their place supplied by other mills made in the Tiber by Belisarius, which continued in use for a long period. The ruins still visible in the river, opposite the mouth of the Cloaca Maxima, are supposed by some to have belonged to these mills. They were of wood only[168], and may have been built on the stone foundations; but these ruins in the river more probably belonged to the fortifications at the head of the Port of Rome, where there was a chain across the river to prevent boats from being carried down by the rapid stream into the Port[169].

Immediately outside of the Porta S. Pancrazio the _specus_ forms the boundary of the beautiful garden of the Villa Pamphili-Doria, on the northern side, for about a mile. It is faced with fine reticulated work of the time of Trajan, excepting where it has been clumsily repaired with brick in the time of Paul V., and it has a wall built upon it. Shortly after passing the limits of the garden, it arrives at the old junction or fork where the stream was divided into two branches, one going to the fountains in front of S. Peter's and the Vatican, the other to the great fountain rebuilt by Paul V. above S. Pietro in Montorio, as before mentioned. In this part the _specus_, being above ground, had been much mutilated, and the engineers of Paul V. found it more convenient to change its course and make a new _specus_ for a short distance, than to repair the old one. The ancient reservoir and the fork in the _specus_ were abandoned, and new ones made about a hundred yards off, on rather a higher level. The old reservoir or _castellum aquæ_ was turned into a farm-house, by piercing the walls with windows and doors, and putting on a new roof. The original arrangement for the separation of the great stream into two smaller ones may still be seen in the farm-yard. The old _specus_ is here just below the level of the ground, with its reservoir, but there is an opening into it. A portion of it can also be seen under the Villa Spada, just within the Porta di S. Pancrazio. From the point of junction, or rather of division, to La Storta, and nearly all the way to the lakes, the _specus_ is underground; but the line of the branch added by Trajan can be traced by the respirators as far as the junction, ten miles from Rome, where, in the year 1830, an inscription[170] was found on the Via Claudia, near the tavern of La Storta, stating that Trajan had carried this water into the city at his own expense in A.D. 109. In the inscriptions put up by Paul V. after his repairs, A.D. 1611[171], the Alsietina, Sabatina, and Trajana are all considered as the same.

XI. TRAJANA OR HADRIANA[172] (?), (A.D. 120).

"In the time of the Emperor Nerva the health of the eternal city was sensibly improved by the increased number of castella, public works and buildings, and cisterns. Nor was his generosity less for the benefit of private individuals, so that those who had previously timidly obtained water in an unlawful manner were now allowed to do so by his favour. Lest some of the waters should perish uselessly great cleanliness was adopted, and there was better ventilation, and the causes of the bad climate for which the city was formerly infamous were removed. I must not pass by the necessity for a new distribution of the waters; but this, with the

increased quantity we have added, can easily be arranged, that is, when the work is completed[173].”

These and other passages in the work of Frontinus shew that great works were carrying on under his direction, not then completed, their object being to improve the quality of the water, and to supply an additional quantity in case any of the existing aqueducts should fail, as they did occasionally, and to increase the power of distributing it, with a view to improving the climate. This is a proof that Malaria existed at that time[174], and that the best remedy for it was an abundant supply of water in the hot weather, for which the subterranean aqueducts were most useful. The improvement of the Aqua Alsietina, and the addition of the Sabatina, were not sufficient for both these purposes; and, as they supplied the district of the Trastevere only, this could not be all that was intended by Frontinus in describing the great works begun by him under Nerva, carried on by Trajan, and completed by Hadrian. The only work which will correspond to this account is the great aqueduct called by modern writers the Aqua Alexandrina, and erroneously attributed to Alexander Severus only.

The sources of this aqueduct are about three miles from Gabii in a watery meadow, nearly under La Colonna, the ancient Labicum. The reservoir of the Aqua Felice is in the same meadow, very near that of Hadrian. Several of the springs that supplied that of Hadrian were intercepted by the engineers of the Aqua Felice, who mistook these springs for those of the Aqua Marcia, shewing their ignorance of the line of the aqueducts. One of the streams, which is rapid and has a considerable body of water, is not used, because the water is of bad quality, and is so full of chalk that it is a petrifying stream. The first central _castellum_ and _piscina_ of Hadrian remains nearly intact, lined with the usual brickwork of that period, but much disguised in outward appearance. It is divided in the inside by a rough stone wall, as was frequently the case; the upper chamber to it has an external staircase added, and windows pierced in it, giving it now the appearance of a mere farm-house. Here the _specus_ is perfect, and from hence it goes at first on a substructure, then on an arcade across the fields, and along the line of arcade to the Cento Celle. The part near the reservoir is destroyed, as is the opposite end near that place, but great part of the arcade in the intervening portion remains nearly perfect, and is one of the finest arcades of the aqueducts, extending for miles across the country between the Via Gabina and the Via Labicana. In some places it is double, one arcade over another, to cross a low valley or a stream. At about a quarter of a mile from the source, the _specus_ is open in two places, so that a man can walk along it, being nearly six feet high and three wide. Small openings have been left on the sides of the _specus_ at regular intervals to let the chalky water escape; and in falling from above it has left the marks of a small cascade in each place, in the form of stalactite, a solid deposit of chalk or lime or tartar against the side of the piers, down which it ran. These petrifactions continue all along the line as far as Cento Celle, and near that point there is a part where the stones and bricks of the arcade have been carried away for building-materials, and the masses of hard chalk remain standing up from the ground, in small pyramids, having very much the appearance of concrete respirators belonging to a subterranean aqueduct; but this appearance is deceitful. There is no pipe in them; they are merely petrifactions formed by the deposit of the chalk from the water.

By the side of the line there are some fine _piscinæ_ and reservoirs, of _Opus Reticulatum_, at intervals, belonging to the time of Trajan or Hadrian. Some of the arches near the sources seem to be earlier. The brickwork is so fine that it appears more like the work of Nero; but most of the work agrees well with the time of Hadrian, and Visconti states that an inscription of Hadrian[175] was found at the reservoir in his time, towards the end of the eighteenth century, and given up to the Borghese family, the proprietors of the ground, who also drained the lake of Gabii, with the aid of Canina the architect. This inscription is believed to have been sold to the French, with other things.

The character of the construction of the _castella_, or reservoirs, does not agree with the time of Alexander Severus, but suits perfectly well with those of Nerva, Trajan, and Hadrian, whose works are so well known. It is work of the first or second century, not of the third. It does not follow the line of the Via Gabina, but is carried at once to the south of it, towards the Via Labicana, and passes nearly parallel to it between those two roads until it crosses the Via Labicana at five miles from Rome, at the place called Cento Celle.

The bad effect of the petrifying stream was noticed by the engineers of the Aqua Felice, and, as that stream was carefully excluded by them, it now runs to waste through the meadows. This discovery was probably made before the third century, and the _specus_ being then found to be choked up with stalactite, was restored to use on a higher level by Alexander Severus. Although the _castella_, or reservoirs, are all of the time of Trajan and Hadrian, the _specus_ and the arcade to carry it is of two periods, the later portion of it being of the third century. The principal intention of this aqueduct has been originally to supply the great villa of Hadrian at Cento-Celle, but a branch of it does appear to have been brought into Rome. Although it is very difficult to trace it for the last two miles, this may arise from the general use of all the aqueducts near Rome as quarries, by the engineers of the Aqua Felice. In the excavations made in 1871, in the high ground near the Minerva Medica, between the Porta Maggiore and the Porta di San

Lorenzo, by the side of that portion of the Marcian arcade that has been mentioned as found there, was also part of another arcade of an aqueduct of the third century, which may have belonged to this, and it was in that neighbourhood that the inscription belonging to the aqueduct of Severus was found.

About a mile nearer to Rome, at the Torre Pignattara[176], or Mausoleum of S. Helena, there is a branch from the Marrana, passing under the Aqua Marcia, apparently to convey water to an imperial villa. The construction of the arcade of this branch to the south of the road is not of the same period as that of the other arcade on the other side to the north. It is usual for modern topographers, following Fabretti, to consider this branch a continuation of the Aqua Alexandrina; but as the water from the Marrana, which is at a considerably lower level than the Aqua Marcia, runs _down_ the gentle incline of this arcade towards the road and the Mausoleum of S. Helena called Torre Pignattara, this is impossible. The construction is chiefly of the fourth century. The Mausoleum of S. Helena is on lower ground than this part of the Marrana.

Constantine is said to have built a villa for his mother near her tomb; but there are no remains of an imperial villa nearer than those called the Cento Celle, a mile further along the road, or the one called “Torre de’ Schiavi[177],” i.e. Tower of the Slaves, about a mile across country, on another road, but on the same level. A milestone for the third mile, found opposite this mausoleum, with an inscription of the time of Maxentius, has been published by Ciampini. This indicates that some works were going on there at the end of the third century, and the arcade may be of that period.

A large and a very remarkable reservoir of the time of Trajan or Hadrian remains a little to the west of the mausoleum, and on rather higher ground. This was probably to receive the water for a branch to the imperial villa, afterwards taken possession of by the Gordiani, who built at that place their great family mausoleum, on which a tall medieval tower was afterwards erected; of this, very picturesque ruins remain, under the title of Torre de’ Schiavi. There are at the same place other large reservoirs of the time of the Gordiani, shewing that the great imperial villa was still supplied with water from the Marcian aqueduct in the third century.

No water under the name of Hadrian is mentioned in the Regionary Catalogue of the fourth century, it is therefore evident that this great aqueduct was not called then after that emperor, although we are told in his life by Spartianus, that many were made in his time, and were at first called after him (as we have said[178]). At the first reservoir, the starting-point, there was an inscription of Hadrian, and the other reservoirs belonging to it are also constructions of the same period. It may be that this water did not come into Rome at all, but that the aqueduct was made to supply the great villa in the place now called “Cento-Celle,” to which it leads in a direct line, and where it appears to terminate. If any alterations were made, these may have been done in the time of Alexander Severus, and this may now represent the so-called Aqua Alexandrina, as Fabretti thought, although he was certainly mistaken in one part of his account of it. The branch which went by the Mausoleum of S. Helena, and which apparently ran underground to the Villa of the Gordiani, was not a branch of the aqueduct to convey water into Rome, but a branch from the great aqueduct for the villa or villas, as it now does from the Marrana at a lower level. This short arcade is of the time of Constantine. The great and long one that leads to the Cento-Celle is of two periods, the earlier part of the time of Hadrian, the latter of the third century. It is quite possible that the original _specus_ had become choked up with stalactite in the course of a century, and that it was restored to use for a time by Alexander Severus, and so called after him.

THE BRANCH OF TRAJAN ON THE AVENTINE.

It has been mentioned in the account of the Anio Novus (IX.) that, after the main conduit reached the great reservoir at the arch of Dolabella, it was divided into three branches, and that one of these was not completed until the time of Trajan and Hadrian. This important branch was carried over the valley between the Cœlian and the Aventine on a lofty arcade, built upon the _agger_ of Servius Tullius, and over the Aqua Appia, also passing over the Via Appia upon the arch of the Porta Capena to the Piscina Publica. It then ran along the edge of the cliff to the north of S. Balbina, and crossed again the valley between the Pseudo-Aventine and the Aventine itself, a little further to the west, by the side of the road which goes down the hill towards S. Prisca. In the vineyard of S. Prisca a portion of the _specus_ remains perfect, at a very high level[179]. From thence it was carried across the hill to the cliff above the Tiber, where the monastery and garden of S. Sabina are now placed. These are on the site of a palace of the time of the early Empire. Some extensive and important excavations were made there in 1855-57, by the Dominican monks of S. Sabina, and among the discoveries then made were an extensive series of conduits, with a _piscina_ and a _nymphæum_ of the same period,—of the end of the first and the beginning of the second century of the Christian era. A cascade _specus_ served to conduct the surplus water down to the more ancient cave reservoir at the mouth of the Aqua Appia, at the Salaria. An account of these excavations was drawn up by M. Descemet[180], and published in the Memoirs of the Institute of France, with an excellent plan and section. Several brick-stamps, of which the words are given in that work, with the names of the consuls, and some terra cotta

water-pipes, with the name of Trajan, were also found here. Others were discovered on the Aventine and near the same spot by Fabretti, who was puzzled by them, because they did not agree with his theories about the aqueducts. Donatus also mentions some of the same facts as known in his time. Some of the bricks were made at the kiln (_figlina_) of Annius Verus, said to have been on the Aventine, near the Salaria; and, if this is correct, that was the spot where they were found. Others have the stamp of Trajan himself. Another is the work of an Arabian servant of Q. Servilius Pudens, A.D. 139, when the Emperor Antoninus Pius and C. Bruttius Præsens were consuls. A piece of leaden pipe, with an inscription upon it, AQVA TRAIANA, was also found on the Aventine.

XII. AURELIA, A.D. 185, AND XIII. SEVERIANA, A.D. 190.

The Aqua Aurelia of the Regionary Catalogue must be the one made by Marcus Aurelius to convey water to his villa on the Via Appia, usually called the Villa de' Quintilii, where a brick-stamp of the time of Marcus Aurelius (A.D. 162) was found on the aqueduct itself by Fea in the eighteenth century[181]. This water was afterwards conveyed to Rome by his successors, Ælius Aurelius Commodus and Septimius Severus, to supply the great _thermæ_ begun by Commodus and finished by Septimius Severus, which were in the first Regio just inside of the Porta Latina, and must have been begun about A.D. 185[182].

The Aurelia was an important aqueduct, and there are slight remains of its _piscina_ just outside of the Porta Latina on the southern side: its _specus_ was traced nearly to that point in the excavations made in 1871. The modern road is cut through this old _piscina_, forming a foss-way in this portion: the aqueduct there passes underground, and has been destroyed or is not visible in this part; but, about a mile from Rome, it can be seen on the bank in the western cliff of the valley of the Caffarella. The _specus_ remains as a tunnel for a short distance, and this was laid open at both ends in 1872 under my direction; it had been concealed and covered over with Pozzolana sand, which had fallen over it from the cliff above, but it can now be seen again. The greater part of the _specus_ has been destroyed, and used for building the large modern farm-house on the opposite side of the valley, the building material having been good brick. As it would not pay to destroy the tunnel, that was let alone.

These remains of the _specus_ are near the well-known tomb called Dio Ridicolo. To this point it runs along the bottom of the valley at the foot of the hill on the side of the small stream or Marrana, here artificial, and parallel to that branch of the river Almo. This open conduit was probably made in the twelfth century, at the same time that the other branch of the Almo, which runs through Rome, was altered and made into a canal or mill-stream where necessary, in order to keep up a constant supply of water, and to avoid its being wasted in floods.

Let us now trace this aqueduct _backwards_ from Rome, in that part near the city. At the Nymphæum, called the fountain of Egeria, it turns at a sharp angle up to another small _castellum aquæ_, close to the church of S. Urbano, which is usually mistaken for a tomb; but the walls are lined with _opus signinum_ or _coccio pisto_, the invariable test of an aqueduct. At this point it turns again towards another fine _castellum aquæ_, at the end of the Circus of Maxentius and of his son Romulus. It comes on there from the head of the valley of the Caffarella, and to that point from the villa of the Quintilii in the Via Appia Antiqua. Thus far we have traced its course _backwards_ from the _thermæ_; in order to identify it more clearly, we will now go to the sources, and bring it down to the same point to which we have traced it from the _thermæ_.

The sources or springs are on the side of the hill of Marino, below Grotta Ferrata, in the same swampy district as those of the river Almo, and of the old aqueducts of the Tepula and the Julia. Several springs are collected into a central reservoir; and, as is usual with other aqueducts, they are then brought into a _specus_, at first underground to the foot of the hill, then upon an arcade, of which there are considerable remains at the Torre di Mezza, Via di Albano, about seven miles from Rome. This fine arcade of the third century goes on to the villa of the Quintilii, and was no doubt built under Aurelius Commodus, after he had obtained possession of that great and fine villa. In various parts of that great building are remains of reservoirs for this aqueduct, and of baths connected with them[183]. About half-a-mile nearer to Rome is, at an angle, as usual, another large reservoir, which has been turned into a farm-house; and the appearance of a medieval chapel or church has been given to it, by building a tower at one end. Possibly it was used for that purpose in the Middle Ages. From thence to the head of the valley of the Caffarella is but a short distance. Where the _specus_ has been carried on an arcade above ground, it has been destroyed as a quarry for the good old bricks; where the ground is higher and the _specus_ is underground, it has been traced in parts only.

THE THERMÆ of Septimius Severus and Commodus were close to each other, and probably connected. They are mentioned together in the Regionary Catalogue as in the first Regio, and there are remains of them under the small hill, called Monte d'Oro, probably, from the golden colour of the sand in its original state, which is situated just within the Porta Latina, between that and the

Porta Metronia. Some excavations were made there in 1870 by the Archæological Society, and large subterranean chambers and corridors were found similar to those under the Thermæ of Antoninus Caracalla. The _specus_ of an aqueduct was also followed for a considerable distance in the direction of the Porta Latina. This must have been for the Aqua Severiana. Just outside of that gate are remains of two _piscinæ_ or _castella aquarum_, one on either side, and on different levels. One of these belonged to the Aqua Aurelia, the other to the Severiana. The course of this latter is more doubtful, but it was probably only a branch from one of the great aqueducts, and would appear to have come in the bank on which that part of the wall of Aurelian was built, from the Porta Metronia to the Porta Latina. It arrived at the bridge over the Almo (on which the gateway-arch of the Porta Metronia is built), from the great _piscina_ and _castellum aquæ_, on the cliff of the Cœlian, near the Porta Capena and the Camenæ, where two aqueducts are now visible, having been brought to light by the excavations of the Archæological Society. The construction of one of these aqueducts agrees with the time of Septimius Severus.

XIV. ANTONINIANA, A.D. 215.

This aqueduct enters Rome at the south-east corner near the Porta di S. Sebastiano, and passes over the arch of Drusus; a part of the arcade is visible by the side of it. The _specus_ can be seen both in the wall of the city, through which it passes, and over that arch, and one of the arches of the arcade remains on the east side of it. It was carried in that manner for some distance across the valley or foss, until it reached the high bank of earth on which the Wall of Aurelian is built, near the Porta di S. Sebastiano, and then along the edge of that bank, which is the great _agger_ of the ancient earthworks, against the outer side of which the Wall of Aurelian is built. The inner side of the bank is supported by a low wall here as in many other parts, and upon or against that inner wall the _specus_ of the aqueduct is carried. It is sometimes on an arcade, in other parts it is carried on the wall to the Thermæ of Antoninus Caracalla. The demolition of part of this arcade in modern times is recorded by contemporary authors.

The _specus_ passed upon an arch over the road in the old foss outside the wall into a garden on the opposite side, where it can be seen on the level of the ground; thence it can be traced through that large garden or vineyard as far as the railway, which passes on the outer side of it in a deep cutting. The remains of the brick arcade here form a wall between this garden and another. It is covered with shrubs, and looks like a hedge, from which circumstance it has hitherto escaped observation. The wall is cut through by the railway, but can be traced on the other side of it along the bank of a narrow deep lane, like what we call in England a Devonshire lane. This lane goes parallel to the Via Latina, on the southern side of it, for about a mile; the aqueduct then leaves it, turning short to the left. Near to this angle, at about half-a-mile outside of the Porta Latina, is a large reservoir belonging to this aqueduct. It is built against the western cliff of the valley of the Caffarella, the top of it level with the summit of the cliff, and therefore is not visible from above, as a person standing on the higher ground looks over it. It is also hidden by a clump of trees; but it is very distinctly visible from the valley below, and from some parts of the Via Appia, and is readily seen to be a _castellum aquæ_ by the boldly-projecting buttresses to support the wall with the weight of water behind it. The Aqua Antoniniana ran along the edge of the cliff, and supplied this large reservoir, which is oblong as usual, and divided down the middle by an arcade, similar to the fine one of the Marcian near Tivoli, and many others. This has been plastered over, and made into a cow-house. It is far above the level of the Aqua Aurelia, which runs below along the side of the valley of the Caffarella. The Aqua Antoniniana clearly came from the higher aqueducts in the main line; and, according to the Einsiedlen Itinerary, it was a branch of the Marcian which went to supply the Thermæ of the Antonines called that of Caracalla. Part of the brick arcade, with the _specus_ upon it, is here visible in another garden against a cliff; it then passes underground for a short distance, but soon emerges again, and can be traced against another cliff as far as the Via Latina, which is here upon a bank, or rather on the edge of higher ground, with the remains of a _piscina_ by the side of it. The _specus_ then again passes underground for some distance, and the next point where we have been able to find it is an old stone quarry, the vault of which fell down in 1870, and revealed this _specus_, which was not visible before. This is in the garden behind the Albergo de' Spiriti, on the Via Appia Nova, about two miles from Rome, and near the point where it crosses the old Via Latina[184].

A large reservoir remains near the Porta Furba, about a quarter of a mile nearer to Rome, and just two miles from the Porta Maggiore. Here we excavated (in 1871) this large subterranean reservoir, near the Claudian arcade on the southern side, but not very close to it, rather nearer to the road to Tusculum (Frascati), which passes near the Porta Furba. This reservoir appears to have belonged to the Anio Vetus, which agrees with the account in Frontinus, of a branch of the Anio Vetus at two miles from Rome, going in the direction of a new road. The _specus_ crosses the Via Appia Nova near the Albergo de' Spiriti, and the Via Appia Nova was probably a new road in the time of Frontinus, as indicated by the tombs of the first century along the side of it.

XV. ALEXANDRINA, A.D. 225.

The Aqua Alexandrina is distinctly mentioned by Lampridius in his life of Alexander Severus (c. 25), as made to bring water to his _thermæ_, which were near those of Nero, and therefore near the Campus Martius and the Pantheon in Regio IX. This could only have been a branch from the Virgo[185], as there is no aqueduct of the third century along the Cœlian, and no trace of a branch from the Palatine or the Capitol.

There is no probability in the theory of Fabretti, that the great aqueduct coming from Gabii, on the eastern side of Rome[186], was the one mentioned in the life of Alexander Severus as made by him to carry water to his _thermæ_, near those of Agrippa, in the Campus Martius, on the northern side of Rome. A branch from the Virgo on the Pincian, or from one of the great reservoirs on the eastern side of Rome, could be made at a tenth part of the cost. There is some reason to believe that there was such a branch passing near the Barberini palace.

Another branch may very well have been made from the great aqueducts between the Porta Maggiore and the Porta S. Lorenzo, to the Nymphæum of Alexander Severus, on the Esquiline in Regio V. An inscription relating to this is said to have been found at the _piscina_ in the garden of S. Croce[187]. It is far more probable that this inscription was found on the wall of the great reservoir, on the other side of the Via di S. Maria Maggiore, near the Minerva Medica, where other reservoirs of extensive _thermæ_ of the third century are visible[188]. These were supplied with water from other reservoirs just within the Porta Maggiore belonging to the different aqueducts; the Anio Vetus, the Marcian, and the Claudian, all appear to have contributed their share. The one specially called Alexandrina was probably the lofty one carried upon a tall arcade, from the reservoir of the Claudia near the Baker's tomb,—forming part of the present city wall. The lower part of the piers of the arcade of this period may be seen built up in the wall; the arches lead to another reservoir between that and the building called the Temple of Minerva Medica, and are there brought to an end, just on the south side of the new arches made for the railway. The _specus_ or conduit, and the arches for it, on these brick piers of the third century, have been rebuilt for the Aqua Felice, in the same rough way as that _specus_ is usually built; but, as that conduit is carried on to the Porta S. Lorenzo in the wall, and as these piers of the third century cease exactly at the point where the conduit of that period would naturally turn off, there seems every probability that this was the Aqua Alexandrina, which was merely a branch from the Claudia and Anio Novus united to supply these _thermæ_, just as the Aqua Antoniniana was a branch from the Marcia to supply the _thermæ_ of Antoninus Caracalla.

The _specus_ of this branch was carried over the Julia on the Marcian arcade to the point where it terminates, which is exactly in a line with a lofty _piscina_ and _castellum aquæ_, now a gardener's house, between the wall and the Minerva Medica, and there are remains of the tall arcade from one to the other; the last pier which joins to that building looks like a large tall buttress to it.

The Temple of Minerva Medica is a brick building of the third century, agreeing with the time of Alexander Severus, and there has evidently been a fountain of importance in the middle of it, with an aqueduct to carry water to it from the large _castellum_ near to it. Upon this _castellum aquæ_ a villa of the sixteenth century has been built; but the vaulted chambers, with the tartar deposit of water, remain in the lower part of this building, and there is a tomb or _columbarium_ of the third century at one end of it.

The dedication of a temple to Minerva Medica, in connection with an aqueduct, is natural, and that this was not an isolated example is shewn by an inscription found near Subiaco[189], and published in 1830 by Martelli, in his work on the Antiquities of Sicily[190]. The Regionary catalogue of the fourth century gives, in the fifth Regio, which contains the Esquiliæ, the Nymphæum of Alexander and the Minerva Medica, all which agrees with the existing remains of this Nymphæum. In the same vineyard, to the north-west or opposite side of the Minerva Medica, and very near to it, are the ruins of another building, called by some "a _nymphæum_," now also a gardener's house, under which the marble pavement remains very evident, the construction belonging to the period of Alexander Severus[191].

Both the Pantheum or hall for the men, and the Nymphæum or hall for the women, had images in the niches round them, and frequently an altar also, so that they were temples at the same time that they were used as waiting-rooms for the baths. The Pantheum of Agrippa was the entrance to his _thermæ_[192]; the building usually called _the Temple_ of Minerva Medica, from an image found there, is called in the Regionary Catalogue Minerva Medica only. A Nymphæum and a Pantheum equally required a _castellum aquæ_ to supply it with water for the fountains and the stream that ran round it, and there are remains of bath-chambers and niches outside of many of the larger reservoirs, as in this instance.

During some extensive excavations, which were carried on in the spring of 1871 by a company, with a view to building new streets in the eastern part of Rome, considerable remains of the lower part of the walls of these great _thermæ_ of the third century were found on both sides of the road made in the sixteenth century, from S. Maria Maggiore to S. Croce. The company bought two large

vineyards, in one of which stands the fine ruin called Minerva Medica, which was evidently one of the halls of the _thermæ_; the ground is full of ancient reservoirs for water at different levels, some underground, others at a considerable elevation, turned into houses; they may be traced at intervals all along the line within the Wall of Aurelian, from the Porta Maggiore to the Porta S. Lorenzo, which is itself here built against the Marcian arcade, and in one part the outer wall of the large _piscina_ and _castellum aquæ_ of the Tepula is incorporated with the wall, of which it now forms part. This ground had been at one period the Esquiliæ or great burial-ground, and afterwards the garden of Mæcenas, so that remains of great works for the supply of water at different periods were likely to be found there, as was the case.

XVI. THE ALGENTIANA, A.D. 300.

This aqueduct is said by some to be only a branch from the Aqua Marcia from the _castellum_ or _piscina_ at the Porta S. Lorenzo, to the Thermæ of Diocletian, and to have been made by him. Considerable remains of the large _piscina_ for these Thermæ were found when the railway station was built, a plan and section of it was preserved by Visconti; it was not destroyed, but was built over and effectually hidden. The aqueduct was continued, A.D. 330, by Constantine to his Thermæ on the Quirinal, now in the Colonna gardens. Others say that the Algentiana comes from the Mount Algidus, near Tusculum. In the Campagna between Frascati and Rome, there are remains of large reservoirs or _castella aquarum_ of the third century, which do not appear to belong to any of the aqueducts hitherto described. They are usually said to be only reservoirs for the supply of the adjacent fields; but they are all on the highest points, and it is difficult to see how the water was conveyed to them. There appears to be a regular line of them, not indeed a straight line, (the nature of the country would not admit of that,) but still a line of them at comparatively short intervals, always within sight of one another. It seems probable that the Aqua Algentiana was brought in a subterranean channel or _specus_ from the great reservoir at Tusculum, which is on very high ground, and that the water was permitted to run into these reservoirs at frequent intervals, instead of being carried on an arcade across the country, as had been done in the case of the earlier aqueducts. It is beyond dispute that the ancient Romans were well acquainted with the principle of the syphon, and that they were quite aware that water will rise to its level after a very considerable distance: they may have therefore thought it expedient in this aqueduct to avail themselves of that principle. It is difficult to explain how water could be supplied to these numerous high reservoirs in any other manner.

XVII. AQUA CRABRA, AND MARRANA, A.D. 1124.

This stream was brought into Rome in the bed or foss of the river Almo (Flumen Almonis), mentioned in the Regionary Catalogue as in Regio I., and not otherwise accounted for in this enumeration. The water now comes from the Marrana, which has its source near Marino, and from the Aqua Crabra, which comes from Rocca di Papa, near the lake of Albano, some miles further up the hill; the waters of these two streams are united before a part of them is carried through the tunnel of the Aqua Julia to a point of junction with the bed of one of the many branches of the small river Almo. The Almo itself comes also from the hill of Marino, but from a different part of it, and is divided into many branches when it arrives on the low ground of the Campagna. One of these was made use of for this mill-stream, a canal being carried in banks of clay in straight lines, where the old bed of the river passed through low ground, and had been therefore liable to floods; but this old bed or foss was used, to save expense, where it passed through higher ground in its old winding course.

Originally that part of the branch which passes through Rome was alternately wet and dry, as many of the other branches are, and was liable to floods after heavy rains. The main branch of the Almo turns off to the south near the Torre Fiscale, following nearly the same line as the cross-road from the Via Appia Nova to the Via Appia Antiqua, and passing under this road twice. In this part of its course it is generally dry in dry weather; but when it arrives at the head of the valley of the Caffarella, several other springs that never fail run into this old deep foss. One comes from near the villa of the Quintilii, another is called the fountain of Egeria, a third the Aqua Santa, from its medicinal qualities. There is a bath-house built over that spring. The original springs on the hill of Marino bring little water in dry weather, not more than sufficient to supply ponds near to them for the cattle; but, in wet weather, the water runs off in the old deep winding foss, which also drains all that part of the country.

The sources of the Marrana are about a mile above Marino, and nearly three miles from Albano; they are in a long, narrow, deep valley in the rocks, and the water gushes out in several places at short intervals on both sides of this valley, which continues on under the rock on which the small town of Marino is built. Close under the town is a tall medieval tower, and at the foot of this is a _piscina_ of rude early character, the lower chamber of which is still full of water. A _specus_ cut in the rock as a tunnel is also visible at this point. On the side of the valley opposite to the town are the splendid ancient quarries of _peperino_, called by Vitruvius _lapis Albanus_, because Marino was in the district of Alba Longa. The stream flows on in the same deep valley, winding

down the hill, and, at the foot of it, the Aqua Crabra, coming from Rocca di Papa, is united with it shortly before it is crossed by the bridge on the road to Grotta Ferrata, ten miles from Rome and near the tunnel through which flows part of the united water, the main body going on straight to the river Anio; the part which is carried through the tunnel turns at a sharp angle to the left, or west, towards Rome. At each end of the tunnel is a loch of early character, partly cut in the rock and partly built of travertine, with the grooves of flood-gates. Over the exit from the tunnel is a piece of old wall faced with _Opus Reticulatum_, of the same rude early character as that of the Aqua Julia.

After the water emerges from the tunnel, it passes in a deep bed to a bridge over the stream of the Marrana, near the _piscinæ_, six miles from Rome. At this point the deep foss of the river Almo is close to it. This is dry in dry weather, but has abundance of water in wet weather, and here the foss is dammed across; this appears to have been done originally to effect a junction with the water of the Marrana, which from this point flows in the foss of one of the many branches of the Almo that intersect the Campagna in this part. This mountain-stream is a very uncertain one; sometimes the deep foss is full of water, flowing at the rate of five or six miles an hour, at other times it is dry. Numerous winding streams are collected into one at the head of the valley of the Caffarella, near the church of S. Urbano. Here it passes through swampy ground at a place called Aqua Santa, on the cross-road from the Via Appia Nova to the Via Appia Antiqua; here also several springs fall into the deep bed, one of which is miscalled the fountain of Egeria[193]. In dry weather this branch of the river Almo appears to begin here, and from thence to the mouth of this branch near S. Paul's, mentioned by S. Gregory as the Almo, the water never fails. All the other branches are deep, dry fosses after dry weather, and the branch that now flows through Rome must originally have been frequently dry, and at other times liable to floods[194].

To remedy this evil, a branch was made from the stream, consisting of the Marrana and Aqua Crabra united, which never fails; and, in those parts where the water passes over low ground liable to be flooded, it is carried in a bank of clay covered with sand, and planted with canes. In such a bank it is carried from near the ford in the natural bed of the river at Roma Vecchia to the Torre Fiscale. Between these two points there is a loch with a flood-gate and a lasher, over which the water falls into one of the deep beds or fosses of the Almo; but this deep bed of a mountain-stream has no other beginning than this same stream, here raised in a bank of clay, into which the water of the Marrana has been turned. In other parts where the ground is high, and consequently the water is below the level of the ground, it follows its ancient, natural, winding course in a deep foss. This is the case both near the original point of junction before reaching the ford at Roma Vecchia, again after passing the Porta Furba, and again under the walls of Rome near the Lateran. From Roma Vecchia, passing by the Torre Fiscale to the Porta Furba, it is carried in a bank of clay many feet above the level of the meadows; but after passing the Porta Furba, it again falls into the old deep foss for about a mile at the foot of the Claudian arcade, winding about sometimes on one side, sometimes on the other, then near to a part of the road to Frascati. For the last half-mile to the Porta S. Giovanni, this road is modern on a large bank of earth across the valley or great foss outside the Wall of Aurelian, and for most part of this line the Marrana is carried in a small bank of clay against the side of the larger bank of the road; but before it reaches Rome it falls again, that is, the earth rises on the terrace under the wall, and the Marrana falls into the old deep bed near the Porta Asinaria, after passing through two mills built on bridges, one on the line of the old Via Asinaria, the other of the old Via Lateranensis.

This small stream enters Rome under the Porta Metronia, which is built on a bridge over it[195]. This bridge has a brick arch of the time of the early Empire, partly concealed by a medieval arch in front of it. Shortly after entering Rome the stream passes at the north end of what is now the nursery-ground of the city, called Orto Botanico, and under a bridge on which another mill is built; by the side of it is the road into that large garden, known to have been that of Crassipes, the son-in-law of Cicero, who mentions in one of his letters a flood of this stream carrying wooden shops from the bank in front of it to the Piscina Publica[196].

This is exactly the direction that the stream takes, as it turns at a sharp angle to the north directly after crossing the Via Appia, and passes close to the Piscina Publica; while the Tiber flows from north to south, and a flood of that river would have carried the shops the other way (if it reached that level at all). There is another mill near the angle on the Via Appia. The stream then passes along a curve at the southern end of the Circus Maximus, (washing the foot of a lime-kiln,) then under the slope of the Aventine and through the gas-works on the site of the Carceres of the Circus, then underground and through another mill in the Via della Marrana near the Bocca della Verità. The eighth and last mill is on the bank of the Tiber, and is built over the mouth of the stream, the back of the building resting on the old tufa wall, called the Pulchrum Littus of the Kings, in which an aperture was left for the Almo when that wall was built. The front of the mill is built on medieval arches standing in the bed of the Tiber.

This alteration of the bed of the Almo may have been made at an early period, of which we have no record, and restored to use in 1124, under Pope Calixtus II., or it may have been entirely made out of the remains of the old aqueducts at that time. We have distinct records of the work done then; but in one of these the expression used is _reduxit_, that is, he "led again" the water from

the old arches. In any case, a great benefit to the city was made at that time, and the account of it fairly belongs to the history of the aqueducts, from which it was made. The following account of it is given by the Cardinal of Arragon, in the time of Pope Calixtus II., A.D. 1124:—

“He (the Pope) also brought water from the ancient arches, and conducted it to the Porta Lateranensis, where he formed a lake to receive it, for watering horses. He also built several mills on the line of the same stream of water, and planted many vines and fruit-trees round the borders of this lake with great care[197].”

Another writer of the same period, called Pandolph of Pisa, relates the same thing:—

“He _reconducted_ a stream of water into the city, and made mills, with vines near a lake[198].”

The ancient aqueduct which was made use of for the purpose was the Julia (V.), (which see,) and the ancient arches mentioned probably mean the tunnel through which the water of the Aqua Crabra and the Marrana united is brought. Its course has been already described, the great reservoir or lake (_lacus_) opposite to the Porta Lateranensis is very distinctly visible in the vineyard by the side of the stream, between that and the Aurelian wall. It is still swampy ground, and is planted with canes; when these are cut at the end of the month of January, it can be clearly seen, and the remains of the lake intercept the path on the bank of the stream. This reservoir might be restored to use with great advantage to the neighbourhood, and at little expense.

There are two mills on bridges across the stream on the side of this lake, and several other mills on the line of the stream, as has been mentioned. The water must always have flowed out of the lake in the old deep bed of the small river Almo, and passed under the bridge on which the Porta Metronia is built, into Regio I., and then under the foot of the Aventine by the side of the Circus Maximus into the Tiber, as before described. The tower built in the twelfth century, against the inside of the gate and the bridge, conceals this from view.

XVIII. AQUA FELICE, A.D. 1587.

This aqueduct is named after the Pope, Felice Peretti, whose title was Sixtus V.; he brought it from a place near La Colonna, the ancient Labicum, about twelve miles from the city, to the fountain of Moses (now so called from a statue) at the Termini on the Esquiline, as recorded on an inscription[199]. It is still in use, supplying the fountains at the Termini, near the Thermæ of Diocletian, of Monte Cavallo, near those of Constantine, and the whole of the upper town. The waters of the Aqua Hadriana were united with some others in the territory called Pantano, at about twelve miles from Rome, where they emerged from the mountains. All these sources or springs of water were collected during the pontificate of Gregory XIII., A.D. 1572-1585, in an immense reservoir, repaired in 1869, with several other smaller ones subservient to it for purification. The aqueduct was built in the time of Sixtus V. (A.D. 1585-1590), but the reservoirs were not completed until the time of Urban VII. or VIII. [1623-44]. From this point the water is carried into the canal or channel through an opening called the _fistula Urbana_, made in a piece of marble. According to Fontana, this water was brought to the Porta Maggiore on a new arcade made out of the materials of the old aqueducts in a very clumsy manner. It was the intention of the Pope to have made use of the canal or conduit of the Aqua Marcia, but that was found to be at too high a level, and his clumsy engineers were obliged to make a new arcade at immense expense. He availed himself, however, of the old arcades as far as he could, by building his new conduit up against the side of the piers of the old ones, sometimes on the Marcian, as may be seen at the place called _Sette Bassi_, and near the Porta Furba, sometimes against the Claudian as near Rome. After bringing it into the city in this canal of rough stone, the water was carried in leaden pipes into the old subterranean channels, as may still be seen in the deep _specus_ on the Cœlian, and the metal pipes pass through the tall brick piers of the arcade of Nero, and are supported on flat arches across from one pier to the other, with a rapid descent over the first or ancient road from S. Croce to the Porta Maggiore, and into the Specus Vetus underground, before arriving at the second or modern one from S. Croce to S. Maria Maggiore. The point of descent is marked by a respirator.

Pantano is about two miles from Gabii, and this reservoir is still in use. It is very near to the ancient _castellum aquæ_, which was made originally by Hadrian[200] for his aqueduct, as is shewn by an inscription found there. The other streams coming from Tivoli are said to have emerged also near this point, and the first engineer of the Felice, Matteo da Castello, considering the Claudian and Marcian lines as the best, followed those to the _piscinæ_; but having made a mistake in the levels, instead of using the Marcian _specus_ and arcade from the _piscinæ_ into Rome, and merely repairing it as the Pope had intended, Fontana was obliged to rebuild it entirely of the materials of the old Marcian arcade, with the help also of those of the Claudian, all the way to Rome. This was done in great haste and in a very clumsy manner[201].

From the Porta Maggiore one branch of the Aqua Felice is carried across the great foss to the Lateran, through the piers of the arches of Nero, and down a cascade-pipe into the old _specus_ of the Appia, and along that to the fountains and reservoirs at the Lateran. This is the branch that goes straight on from the corner of the Sessorium to the west. Another more important branch of the Aqua Felice turns short to the north from the same angle and over the Porta Maggiore, along the city wall to the Porta S. Lorenzo, in a new channel very badly and clumsily built of rough stone from the materials of the old aqueducts, making use of the piers of the Claudian arcade as far as they go, and then of the inside of the wall of Aurelian over the Marcian arcade. The Aqua Felice having here been brought to a higher level, that is to say, the descent from the _piscinæ_ being less rapid than that of the Marcia, after passing the Porta Maggiore, goes over the Marcia upon the Arch of Augustus at the Porta S. Lorenzo. There is a _castellum aquæ_ for it in the wall just to the south of the Porta S. Lorenzo, where the water may be heard rushing through, and the surplus water runs off into an ancient drain on the outside of the wall. With the rapidity of all the public works under that energetic Pope, the undertaking, a decree for which he had signed in April, 1585, was completed in two years, by the labours of from 2,000 to 3,000 men, and the waters were seen to gush from their sculptured fountain in the Piazza di Termini, on the 15th of June, 1587. The Aqua Felice was conducted for fifteen miles underground, and for seven miles upon arcades. Besides the Aqua Felice, the Via Felice and the Via Sistina (Sixtus) in continuation of it, and many other great works were inaugurated by the same Pope, who has been called the real founder of modern Rome. Other old subterranean conduits are employed to carry the pipes of the Felice where convenient for the purpose of conveying water to different parts of the town.

Junctions of the arcade of Sixtus V., or Aqua Felice, with that of the Claudia, take place at an angle where the Torre Fiscale has been built, and again at another angle where there is an archway called the Porta Furba, about two miles from Rome, and a most picturesque ruin of a _piscina_, with a tall tower by the side of it, in which is the ventilating-shaft of the conduit. The difference of construction and of level is very evident, and the three conduits carried on the same arches may be seen distinctly. The construction of the Claudia (VIII.) is of large square blocks of stone. The Anio Novus (IX.) is merely an additional brick conduit, the work is part of that of Claudius and Nero, and is carried over the original one at a great height from the ground. Near the city only small portions of this upper conduit remain here and there, as, for instance, over the Porta Maggiore, and in a few places on the wall. In some places, the arcade of the Aqua Felice runs parallel to the Claudian for a considerable distance, and is joined to it at both ends, as near the Porta Furba. This lower arcade carried part of the conduits of the Aqua Marcia, Tepula, and Julia, which ran from the Porta Furba into the city parallel to the later one of Claudius, at a lower level.

Where the Aqua Felice enters the city, it is carried on the piers of the arcade of Claudius, from the junction with the arches of Nero, over the Porta Maggiore to the old _castellum_ at the corner of the wall, where it turns at a sharp angle. Here the arches of Claudius cease; but the conduit of the Aqua Felice is continued along the city wall, of which it forms part, upon the ancient embankment as far as the Porta S. Lorenzo, and over the archway of Augustus there, using one of the older conduits. It then makes a sharp turn to the west, and after being carried along the north side of the road for a short distance, crosses it again on an archway built for the purpose by Sixtus V., as recorded by an inscription upon it; then it turns sharply to the west again, and is carried on an arcade between the road on the north and the railway on the south, to the great inner _agger_, which it reaches at a point near the Thermæ of Diocletian and the railway station. It is then carried in an old _specus_ in that bank along the east side of the Thermæ, and turns at an angle to the north, at the Via Nomentana, near the Porta Nomentana, a little to the south of the modern Via di Porta Pia; then along the north side of the Thermæ till it arrives at the great reservoir behind the fountain of Termini. The _specus_ is three feet wide, and the water in it is usually from three to four feet deep, running with a rapid current about five miles an hour, and constantly flowing day and night. Thence it is carried in pipes to the different reservoirs and fountains of the upper town. It also supplies the lower part of the city from the Ghetto to the Marmorata, along the bank of the Tiber.

SUMMARY.

Frontinus, who wrote in the time of Nerva and Trajan, mentions (as we have seen) nine aqueducts[202], reckoning as distinct several branches, or additional channels, subordinate to others more important. There is one more important record to which reference has not hitherto been made, namely, the summary at the end of the _Curiosum_ and _Notitia_, in which nineteen are enumerated.

The entry in the Summary of the Regionary Catalogue is as follows:—

Aquæ XIX. I. Traiana [X.] II. Annia (or Anio Vetus?) [II.] III. Attica (Anio Novus) [IX.] IV. Marcia [III.] V. Claudia [VIII.] VI. Herculea [XVII. Almo?] VII. Cerulea [IX.] VIII. Julia [V.] IX. Augustea [I.] X. Appia [I.] XI. Alseatina [VII.] XII. Ciminia (?). XIII. Aurelia [XII.] XIV. Damnata (Cloaca Maxima?). XV. Virgo [VI.] XVI. Tepula [IV.] XVII. Severiana [XIII.] XVIII. Antoniana [XIV.] XIX. Alexandrina [XV.]

Those not previously mentioned are (1.) Attica, (2.) Herculea, (3.) Cerulea, (4.) Augustea, (5.) Ciminia, (6.) Damnata.

1. Attica is supposed by Fabretti to be the same as Alseatina [VII.], but then how is the number of nineteen to be made up? It was probably the Anio Novus, as already described. [See IX.]

2. Herculea. This is mentioned by Frontinus[203] as receiving a part of the Aqua Marcia after its entrance into the city[204]. Another stream of the same name, thirty-eight miles from the city, was added to the Anio Novus[205]; but it seems most probable that the stream here intended is the Almo, which enters Rome under the Porta Metronia, and conveys the water of the Marrana, or Aqua Crabra, coming from these two mountain-streams united, as already described. This is always a very strong stream. It follows the line of the aqueducts for miles towards Rome, and received the surplus water in many places, where there were _piscinæ_; it passes very near to the point where the aqueducts enter Rome at the Porta Maggiore, and may very well have received the surplus water there also of the Marcia, as stated by Frontinus.

3. Cerulea. This is the name of one of the branches of the Claudia, among its sources, and is mentioned in the inscription at the Porta Maggiore; but again, this does not account for one of the nineteen Aquæ.

4. Augustea. A stream was added to the Aqua Marcia by Augustus, and called after him[206]; but that would not account for another stream in Rome here indicated as one of the nineteen Aquæ. It is more probable that the water here intended is the Augustan branch of the Aqua Appia, which was united at the Gemelli within the outer wall of Rome. Frontinus (c. 4), indeed, mentions that the Alseatina was also called Augustea, but that would not account for another of the nineteen streams[207].

5. Ciminia, another name for the Sabbatina [X.], according to Onuphrius Panvinius; but the sources of the Sabbatina are very distant from the Monte Cimino. Ciminia is perhaps written for Curtia, another source of the Claudia; but again, this does not account for another of the nineteen streams.

6. Damnata. This may be the stream that comes from the Quirinal and the Palatine, and which formed the lake of Curtius, whence it was conveyed into the Cloaca Maxima, as it still is. It was therefore _condemned_ to serve for washing out a drain only.

There is reason to believe that some of these nineteen streams are the natural watercourses, and others merely branches from the great aqueducts, as has been said.

There were 1,452 _lacus_, that is wells, or cisterns of water, supplied by the aqueducts in Rome, according to the _Horum Breviarium_ of the _Notitia_, or Catalogue of the fourth century, and they must in many instances have been very near together. A reservoir for the distribution of the water was almost a necessary termination of an aqueduct, and at a junction it was equally necessary.

Rutilius describes the aqueducts about A.D. 417, in such terms as shew that they were not destroyed in the first siege of the Goths[208]. Cassiodorus represents them as perfect, about twenty years before the siege carried on by Vitiges[209]. At the time of the siege by that king, Procopius (i. 19), writing in the sixth century, records only the fourteen aqueducts already mentioned[210].

APPENDIX.—AQUEDUCTS.

Since this chapter was printed, the great excavations that have been carried on in Rome have brought to light many remains of the old Aqueducts in places where they were not previously known or thought of. These are so numerous that we can do little more than mention them, beginning at the Sessorium, where the principal aqueducts entered Rome. In the Sessorian or Palatian gardens, now those of Santa Croce in Gerusalemme, a pit was dug in the reservoir which was used for the Thermæ of S. Helena, which is a large cistern of two narrow chambers, with others similar under them; this was ascertained by digging this pit. Remains of other reservoirs along the line of the north wall of the garden, which is made out of the old aqueduct, were brought to light more clearly. Just outside of this garden is the road from the church of Santa Croce to the Porta Maggiore[211], which is carried on a bank of earth that was the boundary of the Sessorian garden, and on the outer side of it, this bank is supported by a wall of the time of Constantine, no doubt built when his mother, S. Helena, resided there. Just beyond this bank, and in the great foss of the ancient fortress, are two large reservoirs close together, one on either side of the foss. These appear to correspond with the _Gemelli_, or twin reservoirs of Frontinus; an excavation made here was stopped by water, but enough was seen to make it evident that there were other chambers under them, and that they were very deep, but have probably been used for one of the later aqueducts, at a higher level also. It was very usual to carry one aqueduct nearly over another, in order that the older subterranean reservoir might

receive the surplus water of the later and higher ones. It is probable that in this instance the Claudia and Anio Novus had each a reservoir here on the higher level, and that the water of the two was here united and carried on along the Cœlian Hill in one _specus_, on the arches of Nero, to the middle of the city.

The inscriptions on the Porta Maggiore record the distances from the sources of the aqueducts to this point, clearly shewing that this was the entrance into Rome in the outer wall, though not into the CITY, until the boundary of the city was extended to this outer wall by Aurelian, in the third century. On the northern side of this great gate remains of the Marcian arcade were found going from this point, where the three aqueducts pass through the outer wall at one of the angles, and go straight on to the high bank on which the wall of Aurelian was afterwards carried, to the Porta Tiburtina (now di S. Lorenzo), and the reservoirs there. The _specus_ passes underground for some distance, about half-way between the two gates, and is carried on arches near the gates. The fine building called Minerva Medica was full of fountains, as was all the great public garden in which it stands, and all the fountains in Rome were supplied by the aqueducts. Between this building, of the third century, and the wall, is another large reservoir, turned into a house, where considerable excavations have been made. The later aqueduct, called Aqua Alexandrina, was carried in the wall over the earlier ones, to a point just opposite, to the remains of the Minerva Medica. The piers of the arches that supported the _specus_ can be seen in the wall, both outside and inside, as far as this, but they go no farther. This point, where they cease, is close to the place where the railway passes through the wall. Beyond these arches other excavations were made by the archæologists near the Porta di S. Lorenzo, and the arches that carried the Marcia, etc., were shewn. There are remains of two reservoirs near this point; the outer wall of one now forms part of the city wall, and is foolishly called “the house of Cicero;” the other is just within the line, but still on the bank, with the wall of Aurelian built close against it on the outer side. There are remains of another reservoir on the other side of the gate, and one branch goes on from thence to the Prætorian Camp, passing by the Porta Chiusa, where the _specus_ was shewn in some other excavations of the archæologists; and near to it, on the south side, is a large reservoir on the bank, cut through the middle by the wall of Aurelian. This proves that the great bank of earth was there, and had the aqueducts carried upon it, before the time that the wall of Aurelian was built. The _specus_ then goes upon the bank round this camp, but is for the most part concealed; it is visible again on the northern side, which is the only perfect part of the fortification of the camp by Tiberius, and his wall stands upon the earlier _specus_ of the aqueduct; the latter is faced with _opus reticulatum_ where perfect; the wall is of fine brickwork.

The branch that goes from the Porta di S. Lorenzo to the other reservoir, under the Trophies of Marius, is carried on a fine arcade of the first century; this has been brought out far more clearly than it had been for many centuries. The remains of the reservoir at this very high level are also made visible. Signor Ernest de Mauro, the surveyor who took the levels, considers this branch so high, that the only water that could reach it was that of the Claudia and Anio Novus united, which we know from Frontinus was carried into all the fourteen Regiones of Rome, but it was considered by Fabretti to have belonged to the Aqua Julia; the difference of level between the two aqueducts is only ten feet. At this high point the water was divided, and carried in different directions; one branch, of which part of the _specus_ is visible, went to the other great reservoir called the Sette Sale, which supplied the Thermæ of Titus and Trajan on the Esquiline, and the surplus water passed on to the Colosseum and to the fountain called the Meta Sudans. From the other great division of the aqueducts, at the corner of the Sessorian gardens, near the Porta Maggiore, the well-known arches of Nero go along the bank to the Lateran, and from thence along the Cœlian Hill to the great central reservoir of Nero, over the Arch of Dolabella. At that point it has been already shewn that several of the aqueducts met, and were divided into three branches, one straight on to the Palatine, on a double arcade across the valley from the Cœlian, of which there are considerable remains of the lower tier of arches, and one arch of the upper tier, which forms a sort of back gate to the palaces of the Cæsars. A second branch passed over the Porta Capena to the Aventine, at different levels; the earliest and lowest, the Aqua Appia, is the one that can now be the most distinctly traced. After passing over the short _agger_ of Servius Tullius it goes underground under the cliff, at the north end of the Pseudo-Aventine, and at the further end under the hill on which S. Sabba now stands; a series of stone-quarries have been made by cutting away one side of the _specus_, leaving the wells to give air to the quarry.

At this point excavations have repeatedly been made by the archæologists, and as often filled up again by the workmen in the summer months, until 1876, when an arrangement was made with the proprietor to make a more complete excavation, and put up a door to protect it. In this part, which is just before the _specus_ crosses the last road on its way to the Tiber, seven different branches of other aqueducts cast their surplus water into this earliest and lowest; in many parts this was only a tunnel cut in the bed of tufa, and generally half full of a deposit of clay, left by the water which comes from the clayey fields of Lucullus, but in one part it is built of large blocks of tufa, like the walls of the Kings; it is here six feet high and two feet wide; on each side of it is a terra-cotta water-pipe of very early character, and bringing different water in the same tunnel[212].

Near this point it crossed _over_ the road on a bridge (?), or perhaps from the low level _under_ it, at the site of a gate where the four roads meet, to another old stone-quarry of the same kind nearly under Santa Prisca, where the _specus_ was visible in 1874, but is now concealed by some of the vault having fallen in; and from that it has been traced through another series of old stone-quarries to the mouth on the bank of the Tiber, in the very curious cave called that of Picus and Faunus, and Hercules—having previously passed through another reservoir, with water still in it knee-deep, remaining at a considerable distance under the hill, with a _specus_ from thence to the cave at the mouth, partly a natural channel for the water to escape, and partly cut when the aqueduct was made.

The third great branch from the Arch of Dolabella went direct to the Colosseum, and two subsidiary springs still flow there, one under the garden of the Villa Celi-Montana, the other under the garden of the monastery of SS. John and Paul, near to the Colosseum, the latter a very abundant stream, bubbling up copiously; and there are three small pools supplied by it in that quarry, which was formerly called the _Vivarium_, and supposed to have been the place where the wild beasts were kept, but this was a mistake[213]. From that reservoir another branch went in a _specus_ at a considerable depth under the garden of the Marchese Rappellini, behind the monastery of S. Gregory. In this garden there was a landslip in the spring of 1876, and the Marchese thought it probable that the palace of Scaurus had stood there, as it is close by the sloping road called the Clivus Scauri; I thought it more likely to have been the aqueduct which had fallen in, but agreed that the archæologists should excavate it, which was done in May. It turned out to be an old stone-quarry that had fallen in, at the depth of more than 20 ft., but the _specus_ of the aqueduct had passed through the quarry, and remained visible in the pit coming from the cave called the _Vivarium_, and going over the Porta Capena. There is, however, so little of interest left, that the pit was filled up again, after a plan and sketch had been made by Signor Cicconetti.

Another branch of the three aqueducts (Marcia, Tepula, and Julia) went from the Porta di S. Lorenzo along the side of the road or _via_, so called, partly in the bank, by the side of it; the upper _specus_ is now visible, the other two are under it. The whole were underground until the levels were altered in the arrangements for the new city. This branch led straight to the _Mons Justitiæ_, in the centre of the great _agger_ of Servius Tullius. Near this point the four young princes found in their excavation, in 1870, two _cippi_ near together, with inscriptions upon them, stating that the _three aqueducts_ passed between them, and the _specus_ of the upper one, the Julia, was brought to light; the other two, Tepula and Marcia, remained underground. Not much more than a hundred yards from this, another _cippus_ had previously been found, on the top of a well, recording that it descended into the Anio Vetus, which therefore ran under the others, at a great depth in this part, on account of the different levels of the ground, and was then carried along the inner side of this great bank both right and left. The one to the right, or north, going to the gardens of Sallust, or at least a branch from one of the three, went along the horn-work at that corner of the old city, and had a reservoir under the house (now rebuilt by Mr. Spithœver), and then to the _nymphæum_ at the end, and (to the east) of the _Porticus Milliarius_ of Aurelian. In the opposite direction, the left, or south, it went along the inside of the _agger_, on which a row of houses of the first century had been built. It has been found at intervals in several places, one of which is close to the house of Mæcenas. Another branch of an early aqueduct has been found in the tufa rock behind the houses, near the great church of S. Maria Maggiore, on a high level, at the south end of some great building of the first century, or earlier, which was formerly called the _Porticus Liviæ_ and an account of it was published under that name, but the fragment of the Marble Plan of Rome, with the plan of that building and the name upon it, clearly shews this to have been an error. The _Macellum Livianum_, or meat-market of Livia, was found in these excavations near the arch of Gallienus, but there is no connection between the _Macellum_ and the _porticus_, which is represented as an oblong platform, with steps up to it at one end, and with a grand double colonnade all round it. Nothing like this was found near the _Macellum_, and as the earth was carried away to the depth of several feet, if it had been there it must have been found.

In the third century, when nearly all the temples in the Forum were rebuilt, the great public building which forms the north end of that Forum (by whatever name it may be called), was also very much altered in many ways; the main fabric, at the west end, is still original, as it was in the time of Varro, when it was justly mentioned as one of the oldest buildings in Rome. But in the interior great alterations were made, and amongst these, at the west end of the Ærarium (or bank-vaults as they might have been called), the arrangement was entirely altered; the public treasury was transferred to the imperial offices on the Palatine, in what are called the palaces of the Cæsars, and at the west end of the Ærarium an aqueduct was introduced, with a reservoir and a well. A _specus_ of brickwork of the third century is visible, but to which aqueduct it belonged is not easily ascertained; from its level it would agree with the Marcia; it is not high enough for the Anio Novus carried over the bridge of Caligula, though that must have passed near this point; and it is too high for the Anio Vetus, although remains of this have been found also at a short distance; but on lower ground, under, and at the back of a wine-shop in the Via del Consolazione, but quite at the east end of it, and near the corner of the steps

that ascend from it to the door of the Municipio, on the level of the Tabularium, a reservoir that must have belonged to that aqueduct has been found, and the _specus_ traced at the back, parallel to the street, apparently cut out of the tufa rock. Two doors further from the steps the _specus_ is again visible at the back of the shop; and at the same point, but going in an opposite direction, a subterranean passage, which also appears to be cut in the tufa rock, going in the direction of the Piazza del Campidoglio, and said to go as far as the statue of Marcus Aurelius. Whether this had any connection with the aqueduct, or what its object was, is at present not known.

The Plan and Section of the Aqueducts at the Claudium which is also at the end of the arches of Nero, on the Cœlian Hill, the point from which the water was divided into three branches, have been partially shewn in this work, but this could not be done completely until the explorations were made in 1875 and 1876. Subsidiary springs were continually used for the old aqueducts, that no water might be lost that could be used. Of these springs two were found in the space indicated in this Plan, one under part of the garden of Baron Hoffman, near the Navicella, the other under the garden of the monks of SS. John and Paul, in the cave or old stone-quarry which was formerly called a _vivarium_, but which really was a reservoir of the old aqueducts, and this is the most copious spring of the two. It seems almost certain that the water from both these springs found its way into the Colosseum, after the great excavations were made there in 1874-75. To get rid of this water is now (in 1876) a great object. The Government and the Municipality propose, at an enormous expense, to make a new drain from the Colosseum to the Tiber at a great depth. Careful enquiries have been made of the workmen employed in repairing the original drain of the time of Sylla and Scaurus; it was found in a very bad state, and the workmen were afraid to go along it without putting a wooden centering under the old vault, as they were made to fear lest the earth should fall in behind them. This was done for the whole length of the Colosseum, nearly as far as the Arch of Constantine, but the men were then obliged to give up this examination of it for want of air. They state that the main body of the water appeared to come in from under the road from the Navicella, and to run in a continuous stream as if from an aqueduct, and not to bubble up out of the earth as in a spring. This led to the exploration shewn in Plate XXXVI., to ascertain where the water came from[214]. The two springs above mentioned are both on a much higher level than the Colosseum, as will be seen by the Section; and as both are good drinking water, always fresh, it is certain that they must each have some outlet, or they would soon be stagnant and putrid. Every probability seems in favour of these being the springs that supply the inundation of the Colosseum, and if they could be turned off in another direction, as suggested in this Plan, the chief difficulty would be removed. A steam-engine would soon pump the water out, if it did not come in again. The so-called _vivarium_, under the Claudium, is marked on the excellent map of Nolli, in the eighteenth century, as a reservoir for water, which probably had been true; there are three small reservoirs there now which might easily have been united, and the whole be filled by closing the outlet.

Frontinus tells us that the aqueduct of Nero terminated at the temple of Claudius, which was in the centre of the Claudium; this was in fact the sacred enclosure round his temple. A fragment of the Marble Plan of Rome also confirms this, but it is equally clear that soon after the time of Claudius and Nero the water was carried on in three branches, one to the Aventine, another to the Palatine, and the third to the Colosseum, as has been before stated, and there are remains of the arcades of each in all three directions. The _specus_ found in April, 1876, under the garden of the Marchese Rappini, must have come from the reservoir mis-called the _vivarium_, but it had been long out of use.

Many other remains of the aqueducts within the walls of Rome have been found during the great excavations of 1874-1876, in different parts of the city. Some of these have been already mentioned.

Dr. Fabio Gori has sent me an important notice of some excavations recently made between Subiaco and Vico Varo, which throw new light on the line of the _specus_, or channels of the aqueducts, in several places.

On p. 13, note h, it is stated that “the Anio Vetus has its source in the district called _La Connotta_, and passes under the hill of Marano;” but it now appears that the aqueduct in La Connotta belongs to the Anio Novus, because they have discovered at the sources of the Aqua Marcia another aqueduct on a lower level, which must be the Anio Vetus. This is on the opposite side of the river Anio, and passed over the river on the bridge at Vico Varo, of which the great stone piers remain in the bed of the river. He could not find the sources of the Anio Vetus at the fortieth mile, near the bridge of Agosta (twenty miles above Tivoli), because the torrents, in time of flood, have brought down such a quantity of stone in the bed of the river Anio, and the valley through which it flows, that the level of the ground, and of the bottom of the river in this part, is now nearly twenty feet higher than it was when that aqueduct was made.

At p. 60, it is said that Dr. Gori had found the _Piscina Limaria_ of the Anio Novus, made by Claudius, “at the _Prata della Cartiera_ of Subiaco;” that was written when they had found a large aqueduct by the side of the _Emissarium Barberini_; but the recent

excavations have shewn that the water for that aqueduct came from the third loch, near the bridge of S. Mauro, where the opening at the entrance to the _specus_ was found, covered with an iron grating. From this it was inferred that there was a special aqueduct with a private _specus_ to supply the baths and thermæ of the _Villa Neronis Sublacensis_. A quantity of marble of very rare kinds, from this villa, on the margin of the river, has been found, and in the bed of the river the foot of a colossal bronze statue.

The question of the true site of the _Piscina Limaria_, of Frontinus, still remains to be settled, and with it the beginning or source of the great Aqueduct of Claudius, called the _Aqua Claudia_. After carefully examining the bank of the river at a quay at the forty-second ancient mile of the Via Sublacensis, that is to say, between three and four modern miles below Subiaco (which is forty-five miles from Rome), they found the remains of an aqueduct called the _Muraccio_, almost always washed by the water of the river, which enters into it, and then turns at an angle.

On entering into the _Muraccio_, Dr. Gori became convinced that it was the Piscina Limaria of Claudius, as described by Frontinus, c. 15, because the water enters freely into the lower chamber, and to the right the _specus_ of the Anio Novus is seen. The water, according to Frontinus, between the entrance from the river and the _specus_ (_inter amnem et specum_), was stopped and purified in the same chamber, before it entered into the conduit. Considering also that between the three lochs, where the water is now pure, and this piscina, there is a considerable distance. In the rainy season the floods bring down a considerable quantity of earth from the neighbouring fields, which makes the water of the Anio Novus muddy; for which reason the Emperor Trajan began, as Frontinus states, to lengthen that aqueduct to the second upper loch, above the Villa Neroniana Sublacensis. Dr. Gori has found that this work of Trajan was completed, by tracing the whole line of it along the left bank of the river Anio.

ANOTHER AQUA AUGUSTA.

At a meeting of the “Institut de Correspondance Archéologique,” in 1873, the Commendatore G. B. D. Rossi gave an account[215] of another Aqua Augusta, the springs and source of which have been found with that inscription, in the district called _Le Macchie di Rocca di Papa_. This aqueduct appears not to have gone to Rome, but descending into the meadow called the Camp of Hannibal, it went on to the imperial villa at Tusculum, where the magnificent piscina of the time of Trajan or Hadrian is miscalled the House of Cicero.

ERRATA ET CORRIGENDA.

THE AQUEDUCTS.

=Transcriber’s Note:= The errata have not been corrected. Since all notes were reindexed as part of producing this e-text, the note references below have been updated to match the new numbers.

LEVELS OF THE AQUEDUCTS, TAKEN BY ERNEST DE MAURO, 1871.

THE SEVEN SPECUS AT THE PORTA MAGGIORE, ARRANGED ACCORDING TO THE LEVELS ABOVE THE SEA.

I. Anio Novus, 65.000.

II. Claudia, 62.336.

The _specus_ at the Trophies of Marius, 59.936.

III. Felice, 59.560.

Specus on the high ground, between the Porta Maggiore and S. Lorenzo, 59.100.

Reservoir at the fountain of Termini, 58.600.

IV. Julia, 58.192.

Reservoir behind the wall near the Porta S. Lorenzo, 53.000.

V. Tepula, 56.712.

Reservoir in the wall near the Porta S. Lorenzo, 49.525.

VI. Marcia, 54.788.

Specus at the Porta S. Lorenzo, 54.405.

VII. Anio Vetus, 45.688.

Reservoir near Porta Furba, two miles from the Porta Maggiore, 47.193.

Reservoir in the Vigna Berardi, 41.731[216].

Reservoir between the Porta Asinaria and the Amphitheatrum Castrense, 34.030.

Reservoir in the Vigna Mangani, near the Minerva Medica, 47.735.

Two small _specus_ in the Via Labicana, 43.857[217].

Antoniana—_Specus_ in the City wall and over the Arch of Drusus, 40.374.

Aurelia—Reservoir on the south side of the Porta Latina, 36.000.

Severiana (?)—Reservoir on the north side of the Porta Latina, 33.400.

Aqua Marcia Pia[218], 60.088, at the Porta Pia.

HISTORICAL PHOTOGRAPHS OF THE AQUEDUCTS.

[_The numbers refer to Mr. Parker's Catalogue._]

Those marked with * are from drawings, valuable for historical purposes, but not as photographs.

In his admirable treatise on the Aqueducts, Frontinus mentions in his first book, as an introduction, that before they were made, the Roman people, for the space of 441 years after the foundation of the City, were content with the water from the Tiber and from certain natural springs which from their salubrity were supposed to be sanctified.

One of the springs, called Aqua Argentina, deserves special attention; it comes out of the rock in a considerable body, and with much force, under the north-west corner of the Palatine Hill, at a great depth, in the cave called the Lupercal, which from its situation may very well have been a wolf's cave at the time of the foundation of Rome. (702* is the plan and section of this). It falls into the larger stream that comes from the Quirinal and Capitoline Hills, and now runs in the Cloaca Maxima (690*). The point of

junction of these two streams can be seen in an opening where the vault has been destroyed (158), near the arch of Janus and the church of S. Georgio in Velabro, which was the silversmiths' quarter in Rome, as is shewn by the arch they erected in honour of Septimius Severus near this spot, the inscription on which remains.

The stream that comes from the foot of the Quirinal, and now runs through the Cloaca Maxima, emerges in a cellar under a house at the back of the church of S. Hadrian, and a great body of water rises with considerable force. Such a spring is no doubt in its original place. Another spring that runs into this stream is the one that rises in the crypt under the church of the Crucifixion, at the foot of the Capitoline Hill, called the Prison of S. Peter, which is another natural source.

Of the wells or reservoirs of rain-water, we have one remarkable example still preserved; it is on the Palatine Hill, at the north-west corner, just behind the most perfect part of the Wall of Romulus, and at one corner of his _arx_ or citadel, called Roma Quadrata, and there are certain peculiarities about it. It has _specus_, or subterranean conduits, to carry water to it from different parts of the hill. The cistern itself is seven feet high, of about the same width, and of considerable length. Into this reservoir descend certain wells of a peculiar and unusual form, like a hollow cone with the wide mouth downwards. This form of well is said to be common in the east; but the only examples known in this part of Italy are this one on the Palatine under the _arx_ of Romulus, and one at Alba Longa, under the corner of the _arx_ or citadel of that ancient city, from which the Romans are said to have been originally a colony. This is certainly a remarkable coincidence, if it is nothing more. One of these wells is shewn in 764 and 765 from nature, and in 366*, 384*, from a drawing. 1630 is a view of the reservoir at Alba Longa (mis-called the Prison). 1940* is from a drawing of the two compared.

The remains of the aqueduct and reservoir at Tusculum (shewn in 1903) are of _opus quadratum_, of very early character, and seem to shew that the inhabitants there had aqueducts before the Romans. Frontinus, indeed, makes no claim to invention, nor were the Romans generally inventors, they rather turned to useful account the inventions of other people whom they had conquered.

I. THE APPIA—was made by the Censor, Appius Claudius Crassus (Cæcus[219]), in the year of Rome 441, B.C. 312, and has its origin in and near to the Latomiæ or Stone Quarries of the time of the Kings of Rome, on the bank of the river Anio, in which one of the sources of this aqueduct is found.

865, 866, 867

The Caves of Cervaro are a continuation of these Quarries, shewn in 1557.

1155* and 1968* are plans of the sources of the Aqua Appia and Aqua Virgo, in the Meadows of Lucullus, near Collatia.

These meadows are now known by the medieval towers called La Rustica, Sapienza (1551), and Cervaro (1552), and the lines of the aqueduct, crossing them from different springs and meeting in a central reservoir, can be traced by the clumps of shrubs over each well. The aqueduct itself being at a great depth, but still having water in it for the greater part of the year, and moisture always, the line of these wells is thus distinguished. From the central reservoir, in which the water was collected, the _Specus_ or Conduit was carried into Rome, always at a great depth.

The spring of the Augustan branch (added A.D. 10) is found under a cottage (1550), near the town or castle of Cervelletta.

The _Specus_, or Conduit of each of the aqueducts, is distinguished by a slight change of form, and often of size also. Sections of fifteen of these are given in the map, and shewn in the photographs of it, 1982*. That of the Appia being the lowest, and always at a great depth, has been the most difficult to distinguish; but within the walls of Rome it passed along the Cœlian Hill[220] (691*, 890*), and then across the short space between the Cœlian and the Aventine, upon the bank or Agger of Servius Tullius (1100, 1136, 1164, 1165, 1289, 1288, 1166), and very near to (_proxima_) the Porta Capena (1138*). After passing the Piscina Publica, and serving as a drain for the surplus water, it is continued at the foot of the cliff of the Pseudo-Aventine, under S. Balbina and S. Sabba, to the mouth of it (84*) on the bank of the Tiber, under the Priorato near the Marmorata and the Porta Trigemina. The _specus_ is here distinctly visible, filled up with the clay deposit to one-third of its height (1116); the view in the stone quarry and a section of one of the wells is shewn in 889*. A Plan of the stone quarry under S. Sabba shews several aqueducts meeting in it, and throwing their surplus water into the Appia, as the lowest (this is given in 834*, 1941*).

The Reservoirs of this most ancient and very deep aqueduct were first in the quarries before mentioned, and even in Rome were chiefly also in quarries, as at the mouth; but just within the Porta Maggiore, and close to the gardens of S. Croce, formerly the

Sessorian Palace, are two large reservoirs very near together, supposed to have been the Gemelli or twin reservoirs mentioned by Frontinus, and these are so deep that they appear to have belonged to the Aqua Appia. Some excavations attempted in them in 1867 were stopped by water (410, 411, 695*). This aqueduct is believed to have entered Rome on the northern side of these gardens, and to have been first received in the reservoir afterwards called after S. Helena, which is very deep, and in this situation (546).

II. ANIO VETUS, MADE IN THE YEAR OF ROME 481, B.C. 272.[221]

The Anio Vetus and the Anio Novus are in fact branches of the river Anio, which falls into the Tiber a short distance above Rome. The water is there seen to be much more pure than that of the Tiber, and after it falls into the muddy Tiber its clear water can be distinguished for a long distance. Several of the aqueducts, as the Appia and the Virgo, are springs, that fell into that river; but part of the water was intercepted and brought into Rome, each in its own distinct _specus_. This was the case with the Anio Vetus, at a much higher level above Tivoli, but below Subiaco. The river itself may be considered to belong to the system of the Aqueducts, and the series of magnificent cascades by which it falls from its high level, are partly artificial, are connected with them, and illustrate their history. Those in Tivoli (1545, 1546, 1547, 1548), the engineers had great difficulty in avoiding. The one near Vico-Varo (1544), above Tivoli, is near the point from which the aqueduct was taken, which is near the valley called Arsoli (1549). It can be seen in the valley of the Arches, two miles above Tivoli, at the foot of one of the piers of the Marcian Arcade (1054), and the one seems to have followed the other all the way into Rome. It passes along with it over the Ponte di S. Antonio, which is one of the finest bridges on the whole line of the Aqueducts, eight miles below Tivoli, across the valley and mountain stream called S. Antonio (1530). This aqueduct can generally be distinguished by being half-underground, or very near the surface. It was repaired or restored by Augustus and Trajan[222], and most of the remains now visible are of their time, and both the _specus_ and the _castella_ can generally be known by being faced with _opus reticulatum_, so much used at that time. There is a fine reservoir or _castellum_ for it near Tivoli, with very peculiar work of this description, and extremely picturesque (950). Another is against a bank, and half underground, near the Torre Fiscale, three miles from Rome, and close to the foot of the Claudian Arcade (896, 1028, 1029). Remains of others may still be seen at the foot of the Wall of Rome in several places, they were distinctly visible in 1870, when these photographs were taken; but have been almost obliterated since in the _restoration_ (?) of the wall by the municipal architect. One is near the Porta Metronia (983), and another at the Porta Latina (985). Remains of other _piscinæ_ are visible near the Amphitheatrum Castrense, on the rock at the foot of the wall (868, 969, 970); at this point one branch of it seems to have been brought into Rome along the line of the Via Appia Nova, which runs near the spot, and entered Rome just beyond, by the Porta Asinaria. It can also be seen at the foot of a wall by the side of the Via Labicana, near the Porta Maggiore, and readily distinguished by the usual reticulated work (1337). One branch enters Rome at the foot of the Marcian Arcade, close to the Porta Maggiore (59), and the _specus_ was visible at that gate, until it was concealed by a brick wall by the modern builders. It passes through the City Wall there, and is visible on the other side in the inner road, in the wall of the garden still under the level of the Marcian Arcade (1876). Here it forked off, one branch went to the left, along the line of the wall of the garden, to a great reservoir for it at an angle close to the junction of two roads, one called the Via Labicana the other the Via di Porta Maggiore, coming from the church of S. Maria Maggiore. At this spot there is a very large and fine reservoir in several chambers at a considerable depth, corresponding to the level of the Anio Vetus; 538 is a view of it, and 700* is a section of it. From this great reservoir two small _specus_ in this part appear to have gone into the _specus_ of the Appia in the Cœlian, under the Arches of Nero, and are visible going into the bank on which this fine arcade stands (854).

Another important branch turns to the north upon the high bank of the Kings, on which the Wall of Aurelian was afterwards built. There are remains of _castella_ for it near the Porta S. Lorenzo (869), and further to the south near the Porta Nomentana (871), after passing the Prætorian Camp. It had previously gone under the Porta Chiusa, which was shewn in the excavation of 1868, and in the photograph 1057. The _specus_ runs under the wall of the Camp all round. It is still visible on the north side, faced with the reticulated work under the fine brickwork of Tiberius (870). There was an opening into it at the north-east corner of the camp, into which a dog or a boy might be sent (981, 982), until it was closed in the recent _restoration_. Remains of it may still be seen at the foot of the wall in several places by experienced eyes. The general plan of this aqueduct is shewn in Nos. 1970*, 1971*, 1976*, 1977*, and 1967*.

III. MARCIA, MADE IN THE YEAR OF ROME, 608, B.C. 145.[223]

This aqueduct was made in the year B.C. 145, and has its source a few miles below Subiaco; the springs are collected in a small lake called Aqua Serena (1537), the water from which flows into the river Anio; but a portion of it was intercepted for this aqueduct,

and is now again taken from the same spot and brought into Rome. It has always been celebrated for its extreme coldness and great purity. The old _specus_ or viaduct was found in 1870 in this lake, having long been concealed by being under water; but by drawing off some of the water it was brought to light, and the engineer of the new company decided on carrying his new _specus_ up to this point. The previous plan had been to draw the water from another lake nearer to Rome, which is nearly equally good water, but not the real Aqua Marcia so much prized, and this is now again brought into Rome. The source of the old aqueduct is celebrated for its extremely picturesque character, as well as for the fine construction of the arcade of large square stones, and the scientific arrangement of the reservoirs (_castella aquarum_) and filtering-places (_piscinæ_). The sources in the Aqua Serena are shewn in Nos. 1538, 1539. Another source for an additional supply was on the lake of the Mole d'Agosta, 1543.

In the earlier part of its course the _specus_ is underground; but on arriving at the valley called the Valley of the Arches, about two miles above Tivoli, it emerges upon the fine arches which give the name to the valley, and is here carried across the river Anio. These arches are in two series, and are among the most picturesque objects in the neighbourhood of Rome; the effect is improved by a medieval tower built upon the first pier of the bridge. This is shewn in Nos. 1053, 1054.

It then appears again on the other side of Tivoli, on the road called the Promenade of Garciano, which is on the edge of the hill looking towards Rome, and above the winding road up the hill; S. Peter's is visible from this point. On this platform there are a number of fine remains of the _specus_ and of the _castella_ of the Aqueducts, some of the finest of which are of the Marcia. The Plan and Section of a very fine Reservoir and Piscina here is given in No. 535*.

Another very fine one has a wall on the edge of the cliff of the character called Cyclopean (Nos. 1513 and 1528). Chambers of this remarkable early reservoir are shewn in Nos. 1520 and 1521.

A considerable part of this aqueduct was rebuilt by Augustus[224] (B.C. 11), and again about a century afterwards by Trajan[225], and of the _specus_ of that time we have examples in 1524 and 1525, shewing a very peculiar kind of the ornamental construction called _Opus Reticulatum_. Another reservoir of this time is shewn in 1526, and an earlier one belonging to the original construction of the kind called _Opus Incertum_, which probably belongs to the earlier period, is shewn in 1527.

From Tivoli the Aqueducts again pass underground for some miles, gradually winding down the hill from the high level to that of Rome on the Campagna, at about seven miles distance. They were carried upon bridges, some of which are very fine and picturesque, across the gorges of the hills and the mountain streams. At the place where they arrive at the lower ground, there are large reservoirs and filtering-places for them, and the locality is called from them the Piscinæ.

From thence they are carried on the fine and celebrated arcades across the Campagna, presenting some of the finest pictures in the neighbourhood of Rome.

At the Piscinæ, the Tepula and Julia, from the Alban Hills near Marino, were added to the Marcia, and carried on the same arcade. The greater part of them was destroyed, and used for building materials by the engineers of the Aqua Felice in the sixteenth century; but there are some very remarkable and picturesque remains of the arcade at intervals, the more interesting because so little is left of it. One fine piece remains at a locality called Sette Bassi and Roma Vecchia, five miles from Rome (1435), where a small portion of each of the three Aqueducts on an arcade can be seen in Nos. 1006 and 536, and the Piscinæ near to it, 534, 1434, 1438.

This arcade is seen again at the Torre Fiscale, a medieval tower built upon the aqueducts at one of the points of junction, and at one of the angles, which they made at every half mile. Here the more lofty arcade of the Claudia and Anio Novus is carried over that of the Marcia, Tepula, and Julia; while the Anio Vetus runs underground at the foot of it, and the Felice is built up against it; so that at this point seven aqueducts cross each other, and have a tall medieval tower built on the top of them[226]. The Torre Fiscale, with this remarkable junction, is shewn in Nos. 528, 529, 530, 531, 532. A plan and section of it are given in 689*.

There is another angle and crossing at the Porta Furba, half-a-mile nearer to Rome, which makes another very picturesque point of view (shewn in Nos. 551, 552). A small portion of it remains built into a gardener's cottage at another angle, about a mile from Rome, and a fine large reservoir near to it. The ground then rises, and the arcade is buried for some distance; the upper part of the arches of brick, as rebuilt by Trajan, are then visible by the side of the old road that runs close to the northern side of the great Claudian arcade, on the line of the Marcian, which was parallel to the Claudian for some miles into Rome.

It then occurs again very conspicuously at the last angle, close to the Porta Maggiore, where the Claudia was again carried over it, and afterwards incorporated in the City Wall of Aurelian. Here the last pier of the arcade remains with the three _specus_ of the

Marcia, Tepula, and Julia passing through the wall at a right angle (31, 59). Inside the wall a part of the first arch remains with the _specus_ upon it (60); on the other side of the road, the pier of the same arch remains built into the wall of the garden; and a little further on in the garden or vineyard, a gardener's house is made out of another reservoir or _castellum aquæ_ (538; section, 700*).

It then passes again underground parallel to the city wall for a short distance, and near the Minerva Medica it runs into the bank on which that great wall is carried. A portion of this underground arcade was brought to light in some excavations in 1871, but is now covered up again (2320). After passing underground in the bank on which the wall stands for some distance, it emerges near the Porta Tiburtina, now called Porta di S. Lorenzo (see a plan and section of this in No. 1938*). As the ground here is lower it is on an arcade, one arch of which is made into the gate (21, 1870), and a portion of the _specus_ is very distinctly visible on the southern side of the gate, with an opening into it by which persons can go inside of it (shewn in Nos. 69, 572*, and 1487).

After passing the Porta Tiburtina, it went on upon the bank or outer _mœnia_ of Rome to the Prætorian Camp, and there was a large reservoir for it near the Porta Chiusa, remains of which were visible in the excavations of 1868, with the wall of Rome built across it (shewn in 1059). From this reservoir the three aqueducts, Marcia, Tepula, and Julia, were carried along the side of the old road to the inner gate in the great _agger_ of Servius Tullius on the Viminal, where the railway station has now been made, and where the three Roman princes carried on excavations in 1869, in which they found the upper _specus_; that of the Julia, which was left open for a time, passing between the _cippi_ or boundary-stones, with inscriptions upon them, recording that _the three aqueducts_ passed there between them.

Another division of the Marcia went along the same line as the Arches of Nero to the Cœlian, and along that hill as far as the great reservoir over the arch of Dolabella; then turning to the left or south, it came to an end above or over the Porta Capena[227]. These words may mean—either, in the reservoir on the cliff of the Cœlian Hill just _above_ the gate, rebuilt in the time of Trajan, of which the remains are shewn in 1147*;—or, in the reservoir in the valley close to the west side of that gate (also rebuilt in the time of Trajan, and now a gardener's house, as before mentioned). In that case it must have passed over the gate, and the _specus_ that is cut in the wall of the western tower belonged to it (710*).

The general plan of the Aqua Marcia near its source is shewn in 1972*, and the line of its course in 1981*, 1982*; the bridge for it in 1983*.

In the early part of its course, above Tivoli, the new aqueduct for this water, called the Aqua Marcia Pia, is carried on a stone _specus_ upon an arcade, after the same fashion as the old one (a portion of this new arcade is shewn in No. 1553).

IV. THE TEPULA, and V. THE JULIA, being carried on the same arcade as the Marcia for the seven miles into Rome, have left remains visible in some places, especially at the Gates of Rome, the Porta Maggiore (31), and the Porta Tiburtina (21, 572*); in other places, they have generally been destroyed. Near the Sette Bassi, there is a portion of the _specus_ of the Julia visible just at the surface of the ground, the other two being then subterranean, as the level is rather higher in this part than usual. This portion has been examined by Signor Moraldi, at a junction whence a branch was carried to supply a reservoir at the great villa called Sette Bassi, and there are remains of the loch in the channel to turn off the water, shewing the same arrangement as in a modern canal. (A plan and section of this is given in 696*.) The _specus_ near this point, built of concrete faced with brick, is also shewn in 1006. The _specus_ of the Marcia is always of squared stone, so that one is readily distinguished from the other. There are remains of a _castellum aquæ_ or reservoir for the Tepula, near the Porta Tiburtina, or Porta Viminalis of Frontinus, now called Porta di S. Lorenzo. This is shewn in the Plan of that Gate, Nos. 1111* and 1238*, and a view of it in No. 25. It is a remarkable building of brick of the first century, and has on a level with the _specus_ a series of small corbels projecting from it, evidently intended to carry a _hourd_, or wooden balcony as a passage for the Aquarii, and perhaps for defence also. It is incorporated in the great Wall of Aurelian. It projects slightly from the line of that wall, and the end of the _specus_, with its triangular head, is visible in the angle.

V. JULIA.

Between this building and the gate, but within the wall, though on the bank on which it stands, are slight remains of another _castellum aquæ_, supposed to have been for the Julia (Nos. 26, 869, 1873), which has its external face in the direction of the wall, and must have been concealed by it when that was built. This is also of the first century, as is shewn by the brickwork, and it seems to have been a _castellum aquæ_ by the disproportional size of the buttresses used to support the weight of the water, one of the invariable marks of such a structure. The other mark is the peculiar cement with which the wall is lined, called _Opus Signinum_ in Latin, _Coccio Pesto_ in Italian, which is made of broken pottery, and is the hardest cement that is known; it is often impossible to

break it, even after it has been exposed to the weather for centuries.

A plan and section of the ground between the two gates, called by Frontinus Esquilina (S. Lorenzo) and Viminalis (Maggiore), shew the difference of level, and the three aqueducts passing underground in the middle between the two gates, and carried on arches at both ends near the gates (see No. 1938*).

The plan of the ground at the sources of the Tepula and Julia is given in 1980*.

VI. THE VIRGO (NOW CALLED AQUA DI TREVI) WAS MADE IN THE YEAR OF ROME 732, B.C. 21.

This aqueduct has its sources in the meadows of Lucullus, on the banks of the river Anio, on the old Via Collatia, eight miles from Rome, about a mile further than the Aqua Appia, not at the same level, but comparatively near the surface. There are several springs, each of which has its own separate reservoir just below the surface of the ground; in some of them the vault is scarcely perceived. These are also called conduit-heads (864, 863, 862). From each of these small reservoirs a conduit runs into the central reservoir (860, 861), which is considerably larger, circular in form, surrounded by a wall, lined with the cement called _coccio pesto_, and one part of this central reservoir under the road now remains. This is near Salone, with its medieval tower. (See the Plan, 1155*.)

From this large central reservoir the surplus water is carried off by short conduits into the country ditches, and so into the river Anio. The main _specus_ into Rome begins at the central reservoir, and runs generally underground along the line of the old Via Collatina, now called Lunghezza. The course of the aqueduct can be clearly traced by the small pyramidal or conical structures over the wells at regular intervals, called Respirators (660*), or which might have been called Ventilators, as they give air to the _specus_ below. It runs in the high bank of the old road for two or three miles, behind the ruin called Torre d' Scavi, supposed to be the Thermæ of the Gordiani, in a direct line towards the Porta Maggiore; but about half-a-mile before arriving there, it turns sharp to the north along the bank of the great _foss_ or valley, and being underground is traced by the Respirators. Further to the north, beyond S. Agnes, at some little distance, the old line can be traced in the catacomb of S. Priscilla on the Via Salaria, where the _specus_ is visible, half filled up with the deposit of clay (1109*, 1466). In the road on the bank on which the Wall of Aurelian is built, near the Porta Salaria, it can be traced by the low arcade at the foot of the wall which is built upon it (5).

But when the line was altered, it was carried still further to the north, and it enters Rome under the garden of the French Academy (the Villa Medici); it here is marked by two _cippi_ (2088, 2089), with inscriptions upon them, and under the garden is a large reservoir very deep, level with the ground in the great foss on the outside, and with the Campus Martius inside the walls. It was then divided into two branches, one of which went along the Via de Condotti, the other along the Via del Nazzareno (83, 1108*) to the Fountain of Trevi, rebuilt in A.D. 1735 (1356); originally, it went to the north end of the Septa, near the Pantheon. Some remains of this were shewn in 1871 in the Piazza di S. Ignazio (2326). The _specus_ can be seen, with an inscription upon it recording repairs by the Emperor Claudius (82), in the yard behind a house near the Palazzo del Buffalo.

The plan of the ground at the sources of the Aqua Virgo (or de Trevi), is given in 1968*, and Sections of it in 1979*.

VII. THE ALSEATINA.

This aqueduct was made by Augustus in the year of Rome 763, A.D. 10, to bring water for his great Naumachia, or sham naval battles in the Trastevere; the water was not good for drinking[228]. It was brought from the lake called Alseatina, in the hills on the western side of Rome. It is altogether distinct from the great series of aqueducts on the eastern side. The source can be seen in the bank of the lake, and the _specus_ or subterranean conduit can now be entered, the water of the lake having recently been drained, and reduced to a much lower level.

To these was added from another lake about three miles distant from the Alseatina, another branch called the Sabatina. The two conduits were united after a few miles near the old city of Cariæ, at a _castellum aquæ_ or reservoir, now made into a house, and called the Osteria Nuova. The Alseatina was at the lowest level of all the aqueducts, and it is now very difficult to see any remains of it, except the _specus_ in the lake at its source.

Trajan afterwards adopted the Aqua Sabatina, but omitted the Alseatina, and carried the Sabatina at the highest level instead of the lowest (see Aqua Sabatina, Aqueduct X.) Pope Paul V., who restored these aqueducts to use, went back to the Alseatina lake, and his _specus_ can be seen there on a different side of the lake to that of Augustus; both are now left dry. There is, near the junction at the Osteria Nuova, a remarkable flight of steps for the use of the _aquarii_, or the men who had charge of the aqueducts. It

passes through the upper _specus_, and goes down to the lower one (No. 2959*). The respirators of these two lines can be seen and traced; they are of a different size and form. The two can be seen close together at the Osteria Nuova (No. 2960*). The _specus_ is also seen in No. 2961*.

VIII. THE CLAUDIA, AND IX. THE ANIO NOVUS, A.D. 38-52.

These two aqueducts were made together, or were so closely connected that we cannot separate their history, although they were not the same water; the Anio Novus came from some miles higher up the river Anio than the Claudia. The latter was, like the previous aqueducts, taken from springs, that were intercepted before they fell into the river Anio; but the Anio Novus was part of the river itself, in which a gigantic loch was made by building a great wall across it, about a hundred yards in front of a natural waterfall, and forcing the water to flow over it, forming a magnificent cascade, and at the same time causing some of the water to flow through the _specus_ which was cut in the cliff by the side of the river, at a rather lower level than the top of the wall. The sources of the Claudia are below this cascade, those of the Anio Novus are above it. The line of each of these aqueducts is distinct in all the early part of its course; but after they come down to the valley of the Campagna of Rome, at the Piscinæ, the two are carried on the same fine lofty arcade into Rome.

These were the highest, and passed over the Marcian arcade with the three aqueducts upon it. They form the finest feature in the landscape on the eastern side of Rome. The sources are above Subiaco, and in what is considered by artists as some of the most picturesque scenery in the world. The photographs illustrating this are very numerous, the subjects being some of the best that can be imagined for this purpose. The history of these two most important aqueducts can now be better seen in this series of photographs than in any other manner, and better understood than by any written description of them, after the outline of their history is once given.

They were begun in the year of Rome 789, A.D. 38, under the Emperor Caius Cæsar, or Caligula; carried on and completed by his successor, Claudius, in the year of Rome 803, A.D. 52. They were therefore fourteen years in construction, according to Frontinus[229]; but Nero was then married to Octavia, he was the actual governor of Rome, and he carried on the great work upon what are called the Arches of Nero, along the Cœlian Hill, as far as the arch of Dolabella, where a large reservoir for this water was built. This work was afterwards carried on by his successors in three branches, one to the Colosseum, a second to the Palatine, and over it to the Capitol, and a third to the Aventine. Frontinus himself, who has left us his admirable treatise on the subject, had the direction of these works for many years; he was Curator Aquarum under the Emperors Nerva and Trajan, and some of the greatest works were done in his time,—at his suggestion, and according to his plans.

Some of the sources of the Claudia were in the lake of S. Lucia, below Subiaco, between that and Vico Varo (see 1536). In its course through the hills the _specus_ is almost entirely underground, and cannot be shewn in photographs; but the line of its course is shewn in the map of the aqueducts from Rome to Subiaco, reduced by photography in Nos. 1967* to 1984*, especially in Nos. 1976*, 1978*, 1979*, 1981*. It crosses mountain streams on the bridges called Ponte Lupo (1532) and Ponte di S. Antonio (1530); and an inscription relating to it, of _A.D._ 88, is given in No. 1976*.

When it reaches the level ground of the Campagna, nearly on the same level as the hills of Rome, the _piscina_ for it is subterranean, and only the summit of this is visible, looking like a _tumulus_ only (688); but from this the _specus_ is seen to emerge, at first only just above ground, but gradually getting higher (or the soil, in fact, is getting lower), until it is carried on the grand series of arches or arcades across the country, which remain nearly perfect for some miles, as far as the Sette Bassi and Roma Vecchia. In 1002, a long line of this arcade is shewn with the Claudian _specus_ upon it, and the Anio Novus over that in many places; the two can readily be distinguished, by the Claudian being built of large blocks of stone (with the edges chamfered off), and the Anio Novus being faced generally with brick, occasionally with _opus reticulatum_. Nearer to Rome, this fine arcade has been very much damaged, or carried off altogether as building material by the farmers, and by the engineers of Pope Sixtus V. to build the Aqua Felice; but some portions of the old arcade remain, and are shewn in No. 1006, where the distinction between the two _specus_ comes out very clearly. In 1005, two of the brick arches with which it had been strengthened by Trajan are shewn, the stone-work having all been carried away.

In 689*, a plan and section of the Torre Fiscale is shewn, with the crossing of six aqueducts. 528 is a view of this tower and of the arches of the aqueducts crossing each other under it, with the Aqua Felice in the background. 529 shews the arch of the Claudia separately, and the construction of it, with the Aqua Felice passing under this arch of the Claudia. 530 gives very distinctly the arch of the Marcia, Tepula, and Julia, with that of the Claudia passing over it. 531 and 532 are more distant and general views of that

tower, and the aqueducts passing under it. 1439 is a side view of it, and of the old tombs on the Via Latina in that part. 1004 shews the arches of the Claudia and Anio Novus in perspective, and the opening into the _specus_ of the Claudia. In 550, another fine portion of the arcade is shewn, with brickwork of Trajan. The Porta Furba and a long line of the arcade is seen in the distance. 548 shews the Porta Furba at another crossing, with the fountain, and a portion of the arcade of the Felice; with the Marrana in the bed of the river Almo passing under it.

62 is a portion of the Claudian arcade, about half a mile nearer to Rome, with the arches filled up with brickwork of the time of Trajan; at this point there is another crossing. 63 shews a portion of the brickwork of Trajan, originally built to strengthen the stone arcade; but the latter has been carried away by the engineers of the Felice. 549 shews some interesting repairs of the time of Nero, with massive square buttresses faced with reticulated work. 70 is a medieval tower at the angle of the garden of the Sessorian Palace, now of the monastery of S. Croce, near the point where the aqueduct enters the wall.

547 shews the interior of the Tower and a _piscina_, at the entrance into Rome, the four chambers of which are visible, the inner wall of this tower having been destroyed; and into the interior of this the water of the Claudia entered in the first chamber and went out at the fourth. This photograph also shews the remains of a large _castellum aquæ_, now forming part of the Wall of Rome, on the north side of the garden, with a continuation of the arcade in the Wall of Rome in this part. In 544 the _specus_ of the Claudia is plainly visible on the top of the wall, and remains of the Anio Novus over it. In the distance are seen some of the arches of Nero, across the valley and foss (?), from the angle near the Porta Maggiore to the Cœlian Hill. This garden might very naturally be called by Lampridius “The Garden of the Specus,” for the _specus_ in the time of the Emperors must have been the most conspicuous object in it, or visible from it (542).

412 shews another of these reservoirs in the same garden, with repairs in brick by Trajan. The arcade of the Aqua Felice, built against the outside of the Wall, is also seen through the arches of the Claudia.

31. The exterior of the Porta Maggiore, with the _specus_ over it, the lower one the Claudia, the upper one the Anio Novus. (The inscription of A.D. 404 is given in 1872.) Under these, but still on the top of the wall, the _specus_ of the Aqua Felice may be seen, built as usual of rough stone concrete. To the right or north of this may be seen the three _specus_ of the Marcia, Tepula, and Julia, passing through the wall in the opposite direction, now under the Felice, and originally under the Claudia and Anio Novus. These three _specus_ are carried upon one of the piers of the Marcian arcade, built into the great wall. Just beyond these, further to the right, is part of the last tower of the Claudian arcade.

32. The Porta Maggiore, with the _specus_ on it, seen sideways, and the north side of the Baker’s tomb.

The last tower and _piscina_ of the Aqua Claudia; it stands at an angle of the wall projecting from it, and shews clearly that it stood there when the wall was built by Aurelian, and then incorporated into it. When the fortifications of Honorius at this gate were destroyed in 1833, the inscription relating to the aqueduct was preserved and built up to the right or south of the gate (shewn in 1872). Within the wall, behind the tower, is a large reservoir or _castellum aquæ_, of which there are slight remains, shewn in 967 and 968.

A panoramic view of the line of the Claudian arcade, on the north side of the Sessorian gardens, taken from the extreme end of them at the west, is shewn in Nos. 542 and 543. On the left hand is the beginning of the arches of Nero, going across the foss towards the Cœlian; then the Porta Maggiore is seen sideways, with the two _specus_ on the top of it. Under this is part of one of the two great reservoirs believed to have been the Gemelli of Frontinus. Then comes the western wall of the Sessorian gardens, rebuilt by S. Helena, the construction being of the time of Constantine. To the extreme right is the ruin of the Basilica or Great Hall of the Sessorian Palace, repaired by him. This is miscalled a temple of Venus and Cupid on some of the maps.

Having thus traced the Aqua Claudia from its sources into Rome, we must now do the same for THE ANIO NOVUS, which in its early part is distinct from it, as we have said.

1514. Sources of the Anio Novus above Subiaco. The river Anio in the highest point, with which the aqueducts are connected, is seen winding through a gorge in the rocky mountain, with remains of the bars or dams, across the river, forming the two upper lakes or lochs. The celebrated monasteries of S. Scholastica and S. Benedict are visible on the hill to the left.

1515. The River Anio, a little lower down, with remains of the second barrage or dam across it, forming the third loch or lake, with the modern bridge built upon the ruins of the old wall that formed the bar. Chapels of the monks of S. Benedict are visible on the hill to the right.

1534. The Bridge of S. Francis, over one of the branches of the Anio that meet near the rocks before mentioned, above Subiaco.

1517. Remains of a great reservoir or _castellum aquæ_, of the time of Trajan, on the bank of the lake or loch before mentioned. The wall is faced with _opus reticulatum_, with layers of brick at intervals, the usual construction of the time of Trajan.

1518. The modern bridge, far below, and remains of the old high wall on which it is built, are seen under it; below are the cliffs of the third lake or loch, cut into a circular form. In the bed of the stream are large stones fallen from the wall or bar across the river.

1519. Remains of another _castellum aquæ_ above Subiaco, and the mouth of a cave connected with the aqueduct.

1555. _Specus_ of the Anio Novus cut in the cliff of the valley of the Anio. This is below the level of the great bar, and the water was forced to go through the _specus_ into Rome by the bar being higher than the _specus_. A modern winding road has now been cut here, and the rock has been in part cut away, shewing an opening into the _specus_, which is six feet high and two feet wide. Above is seen a tower and an embattled wall of the modern Villa Gori.

1516. Part of the _specus_ of Trajan, who repaired this aqueduct. The _specus_ is cut as a tunnel in the cliff, with a reservoir by the side of it.

1556. A view of the gorge in the mountains above Subiaco, where the three lakes are situated.

1536. A small lake at the source of the spring called Fons Novus Antoninianus, one of the sources of the Anio Novus.

1558. Cascade at the Paper Mill, on the site of a _piscina_ of the Anio Novus, above Subiaco.

1057. Arches of the bridges of the Marcia and Anio Novus, in the Valley of the Arches above Tivoli.

1052. Arch of the bridge on the Anio Novus, in the Valley of the Arches above Tivoli, with a medieval tower built upon it, forming one of the most picturesque objects in the neighbourhood of Rome.

1522. Specus of the Anio Novus below Tivoli, on the road to Garciano, called the Promenade, with openings into it, and an old tomb in front of it. This promenade is through an olive wood, and the roots of the olive trees run into many of the ruins.

1523. One side of a _castellum aquæ_ of the aqueduct above the road to Garciano, faced with _opus reticulatum_.

1529. A bridge across a valley that passes the road to Garciano. This bridge is above the road on the left, in the valley called the Arcinelli.

1531. Ponte de S. Antonio, a fine bridge for the aqueduct below Tivoli, across a gorge. It is seen from above looking down upon it, with the chapel of S. Antony at the end of it, and a medieval castle in the distance. The road for horses, and the remains of the _specus_ by the side of it, are here visible.

1532. Ponte Lupo, near Poli, west side, below Tivoli, the finest of all the bridges of the aqueducts. It crosses a valley from one cliff to the other, and is a solid wall for part of the way, the rest on arches. The two _specus_ are here visible, as seen from below on the west side.

687. Arrived in the valley of the Campagna, the great _piscina_ of the Anio Novus and that of the Claudia, which is near to it, is underground, and the summit of it only is visible, appearing like a tumulus. It is near the old Via Latina, and below the present roads to Albano, Frascati and Marino.

74 and 75. After leaving the great _piscinæ_, the two _specus_ are carried on the fine arcade, of which a panoramic view is here given, shewing its general effect for some miles.

554. Passing by the remains of Roma Vecchia to the Torre Fiscale and the Porta Furba (given under the head of the Aqua Claudia), the _specus_ rises to a remarkable reservoir, which from its great elevation must have belonged to the highest of the aqueducts. It is a most picturesque one, near the Mausoleum of S. Helena, but is earlier than her time; it belongs rather to that of Trajan, being faced with fine reticulated work, with layers of bricks on the exterior. The interior is distinguished by remarkably solid central buttresses, to support the wall against the pressure of the water (553).

926. Another large reservoir of the same period and style, and at nearly the same level; it occurs about a mile further from the main line of the aqueducts, at the place called Torre de' Scavi, where the Thermæ of the Gordiani were afterwards made. This appears

also to have belonged to the Anio Novus, as no other aqueduct is high enough for the water to have reached it.

ARCHES OF NERO.

At the great reservoir inside the Porta Maggiore (the Porta Esquilina of Frontinus), the water of the Claudia and the Anio Novus was united for the general use of the City. This aqueduct entered on the highest ground in Rome, and the water supplied the deficiencies of any of the other aqueducts in case of need. Being a part of the river Anio, it never failed. It was forced to come through Rome, as has been shewn by the arrangements in the bed of the Anio above Subiaco. This united water was carried to all the fourteen Regiones of Rome, and in order to ensure an abundant supply, it was conveyed in the great stone _specus_, on the fine arches of Nero along the whole length of the Cœlian Hill for more than a mile; at the west end of the Cœlian an enormous reservoir was built for it on the level of the _specus_ at the top of these arches, so that the base of the reservoir was fifty feet from the ground, and the road passed under it. From this great central reservoir, at a very high level, the water was distributed in various directions.

Before arriving at the Cœlian Hill, it had to be conveyed to and along the Cœliolum (now the Lateran Hill). It had come through the gardens of the Sessorium, as we have seen, in the two separate _specus_, after it had entered Rome at the extreme eastern corner, on the north side of these gardens, which are nearly half a mile long. These are _the palace gardens_ mentioned by Frontinus. The Sessorium with its gardens (now the monastery of S. Croce in Gerusalemme) had been one of the two Prætorian camps, this one being at the south end of the great _agger_ of the Tarquins, which formed the outer _mœnia_ of Rome on the eastern side. The one, called the Prætorian Camp, is at the north end of the same great bank.

Each of these fortified camps was surrounded by a great wide and deep foss or trench. These great banks and trenches are usually mistaken for natural hills and valleys; but natural hills and valleys are not merely high banks fifty feet high and perhaps a hundred feet wide, nor are natural valleys long narrow trenches of the same dimensions, running on each side of the great banks, being in fact the trenches from which the earth has been thrown to form the banks. Such a bank with such trenches can be clearly traced all round Rome by eyes that are accustomed to examine such things, although modern buildings have disguised them so much that an ordinary observer does not see them. People cannot see over modern walls of twelve feet high, still less over the great Wall of Aurelian fifty feet high, and they do not think of comparing the level of the ground on each side of that wall, nor can they easily do so. These great ancient earthworks were extremely convenient for the engineers of the Aqueducts, which were brought upon the high banks at the farthest corner. They were carried along the bank on the north side of the Sessorium, from its north-east corner to the south-west angle, where the great bank of the Tarquins joins on to it. Some branches of the Aqueducts, perhaps the main stream in some cases, were then carried along this high bank of the Tarquins to the north, as far as the other Prætorian Camp, and beyond it along the outer wall of Rome, as we have seen in the case of the Anio Vetus, the Marcia, Tepula, and Julia. These did not pass through the Sessorium, but parallel to it about a hundred yards on the north of it. The Claudian arcade had been at about that distance on the north of it, all the way from the Piscinæ into Rome. The Marcian arcade was made nearly over the Anio Vetus, which ran between that arcade and the Claudian, but much nearer to the Marcian.

On entering Rome, this main stream went straight on through the great bank to the large reservoir on the inner side. The reservoirs for the Tepula and Julia were much to the north, near the Porta di S. Lorenzo (the Porta Viminalis of Frontinus), as we have seen; that of the Marcia was much closer to the Porta Esquilina. The two great reservoirs, called by Frontinus the Gemelli, were made in the great foss between the Sessorium (S. Croce) and the Cœliolum (the Lateran). They had probably been originally made for the Aqua Appia and the Anio Vetus, being both at a low level, though one was much deeper than the other. Advantage was taken of these ancient reservoirs to erect the higher one required for the reception of the waters of the Claudia and Anio Novus over it, or by the side of it, as was very usual throughout Rome. The later reservoirs are always made nearly over the old ones. This is equally the case here at the entrance into Rome and at the other end of the Cœlian. The great high reservoir of Nero is close by the side of, and really over, the great subterranean reservoir of the Aqua Appia (now under the garden of the Villa Cœlimontiana, as described in the account of the Appia).

The foregoing explanation seems necessary to explain the photographs that now follow, belonging to the Arches of Nero. The first of these (No. 77) shews the junction with the Porta Maggiore; the two _specus_ that pass over that great gate are visible to the right of the photograph. The beginning of the Arches of Nero is then seen, where they have to cross the great wide and deep foss of the Sessorium, and were therefore strengthened by sub-arches, as seen in No. 76. A more close view of these arches, nearly at the same point, is seen in 66.

These arches were used by the engineers of the Aqua Felice whenever they suited their purpose, and cut about or destroyed without mercy; they also made use of an old _specus_ to carry their metal pipes whenever it was convenient to do so, and the _old specus_ that ran along the Cœlian was very convenient for that purpose. 1295* is from a drawing made to shew this. The _specus_ of the Aqua Felice was first carried on the lower arches of the double arcade of Nero, the upper part of the arcade being destroyed. The metal pipes were then carried down into the old subterranean _specus_ (_the Specus Vetus_ of Frontinus). This is in the same garden or vineyard as the Gemelli, in the great foss between the Sessorium and the end of one of the banks of the Tarquins, (on which the garden of the Villa Volkonski has been made, and along which the Arches of Nero run.) A portion of the grand arcade, with the _specus_ very visible on the top of it, is shewn in 759. This is close to the Scala Santa of the Lateran; the arcade carrying the aqueduct passed along the bank on the north side of the Lateran fortress on the Cœliolum, and supplied that with water.

On the western side of the Lateran fortress is another great foss, between the Cœliolum and the east end of the Cœlian Hill. It was either thought more convenient to make a bank across that great foss for the aqueduct to rest upon, or this bank which traverses that great foss had been made before for an upper road, and was used first for the Aqua Appia and the Anio Vetus, and afterwards by Nero. The existence of such a foss between the east end of the Cœlian Hill and the Cœliolum is denied by those who have not paid attention to the subject, and have not been into the gardens and vineyards to examine it; but the fact is a matter of demonstration. The tomb of the first century (miscalled the House of Verus, probably a tomb of the great Lateran family), being on the western bank of that fortress and the eastern bank of the foss, and the other tomb of the first century also, in the garden of what was the Museum of Campana (_under_ an arch that carries the modern road), on the western side of that great foss, are a demonstration that there was such a foss on the east side of the City of Servius Tullius, i.e. that the Cœliolum and Lateran did not form part of the City at that time. (See my chapter on the Tombs, and the photographs of these two tombs, 174 and 1942).

The Arches of Nero remain on the Cœlian in many parts of the line, by the side of the road from the Lateran to S. Stefano Rotondo and the Navicella, with the arch of Dolabella, which was under the great reservoir of Nero, and formed the entrance of the Claudium. The Arches of Nero are faced with the finest brickwork in the world (ten bricks to the foot, as usual at that period, and are chosen as typical examples). This is well shewn in 78, and the internal construction of rubble, faced only with the fine brickwork, in 358. A line of these, shewing the picturesque effect, is shewn in 131 and 357. The aqueduct formed one of the usual angles between the Lateran and the arch at the west end of the Cœlian. It has been destroyed in this part; but this accounts for the arches being sometimes on one side of the road and sometimes on the other.

We have now arrived at the arch of Dolabella, built when he was consul, A.D. 10, as an entrance to that part of the Cœlian Hill which had been the keep when it was a separate fortress, and was afterwards made the Claudium. This arch is of very simple construction, of travertine, the same construction as the early part of the Basilica Julia, built by Julius Cæsar and Augustus. It was used by the engineers of Nero as a foundation for their great reservoir, or rather for one corner of it, as we clearly see in 72. The work of the time of Nero terminated here, but the design was carried on by his immediate successors. The water was then divided into three branches; the one on the right hand, to the north, went to the great reservoir between the Cœlian and the Esquiline, called the _Stagna Neronis_, and was used for the sham naval battles. Around these Stagna the Colosseum was afterwards built. A portion of the arcade on which the _specus_ was carried is visible in the garden of the monks called the Passionists of SS. John and Paul, and is well shewn in No. 1773, looking towards the east, with the ruins of the reservoir over the arch of Dolabella, and the church of S. Stefano Rotondo in the distance. There are remains of a reservoir for this, of the third century, in the garden of the monks on the terrace of the Claudium, opposite to the Palatine, shewn in No. 1765. The ruins of the fine arcade of the Claudium stand on this terrace; the _specus_ also is in a wall here, behind the arcade. A portion of another reservoir or _piscina_ for them can be seen at the foot of the cliff of the Claudium, at its north-east corner, opposite that part of the Colosseum near the Meta Sudans; this is also shewn in No. 1743, with _opus reticulatum_ of the time of Nero. This branch continued in use in the third century; for there are remains of another reservoir for it, again at the foot of the Claudium opposite to the Colosseum, but more to the east, near the north-east corner of the Claudium, and near to the eastern end of the Colosseum. The remains of this reservoir are shewn in No. 1735. A colonnade carrying the _specus_ from this reservoir to the second story of the Colosseum, is shewn on one of the coins of Septimius Severus, who probably built this reservoir. In the corridors of the Colosseum are open stone troughs lined with the cement for water. These carried water from this aqueduct in a constant running stream to cool the air. They are work of the third century, with old inscriptions on some of them, shewing that they were made of old materials.

Another branch from the great reservoir went straight across to the Palatine, and from thence to the Capitol; it first follows the line of the road down the Clivus Scauri, on the left or southern side, and a fragment of it is visible opposite to the church of SS. John and Paul, as seen in No. 305. At the foot of the Clivus Scauri it formed an angle, and passed against the cliff on which the apse of the

church was afterwards built; it now forms the lowest and last of the series of arches that are carried across the road to support the side of the church. Then, after this angle to the north, it resumes its course to the west upon the arches across the valley to the Palatine, which was a double arcade; but the lowest tier of it only remains, as is shewn in 116. A portion of the upper tier is also visible at the end of it; an arch of this upper tier remains, which, having been made into a back gate of the Palatine, has been suffered to remain, and is shewn in No. 72. A large reservoir for it was made at the south-west corner of the Palatine, on which the palace of Commodus was afterwards built; part of this reservoir and _specus_ is shewn in 683 (made from a drawing). The _specus_ went across the middle of the Palatine, and has been found more than once in some of the recent excavations, but not understood. It was then carried on the bridge of Caligula to the Capitol, a small portion of which remains connected with his palace, as is shewn in Nos. 1447 and 1451.

The third branch from the great reservoir over the arch of Dolabella on the Cœlian was made in the time of Trajan, to carry water to supply the thermæ on the Aventine, called after Sura, the cousin of the Emperor; these thermæ were closely connected with the private house of his family, rebuilt in his time, and called in the Regionary Catalogue “Privata Trajani,” of which there are considerable remains, now subterranean. The first place where this branch of the aqueduct is visible is in another reservoir (1147) against the cliff of the Cœlian, opposite to S. Balbina. This is partly above the level of the hill, and has been thought part of the Palace of Commodus, on the Cœlian (which may possibly have been built over it, but the existing remains are of the time of Trajan). The lower part is under this, and is excavated in the cliff. These were brought to light in the excavations of A.D. 1868 (559, 1008, 1009, 1010, 1011). The plan and section of it are to be seen in 1150*, 692*. Against the cliff the aqueduct formed one of the usual angles towards the north, and this was carried across the valley on the _agger_ or bank of Servius Tullius, first passing over the arch of the gate of the Porta Capena, above the Aqua Appia, on a much higher level, and on an arcade, probably a double arcade, like the Arches of Nero near the Porta Maggiore, on account of the great height at which the water had to be carried from one hill to the other. All that remains of this lofty arcade is a line of brick piers passing across from the Cœlian to the Aventine, over the Aqua Appia, before described, and passing by the north end of the Piscina Publica, as rebuilt in the time of Trajan over the old one, which had belonged to the older aqueducts. There are considerable remains of the walls of this period, that divided the chambers shewn in 557, 558, 1288.

This arcade can then be traced against the cliff of the Pseudo-Aventine, on the north side of S. Balbina, though partly concealed by the filling up of the space against the cliff before mentioned. The tall arcade then crosses the valley from the Pseudo-Aventine to the other part of the Aventine, and from the garden of S. Balbina to that of S. Prisca, and, in the latter garden, there are considerable remains of it on the cliff opposite to the Palatine. At the north end is the _specus_ upon the arcade (the top is open, and there is a walk upon it), 79. A small portion of the Thermæ of Sura is also shewn, with the _specus_ in front of the ancient wall of tufa, called the Wall of the Latins (833).

From the _piscina_ and reservoir on the cliff of the Cœlian another branch went to the south, over the spring of the Camenæ (?) 692, and near that of Egeria (?); it was carried over the Porta Metronia, and on the bank of the City Wall as far as the Porta Latina.

Another fine arcade of the time of Nero (No. 1317) leads to the Nymphæum before mentioned, where the Trophies of Marius were hung. The elevation shews that this water must have come from the highest of the aqueducts, the Anio Novus; and the remains of the reservoir near the Porta di S. Lorenzo, supposed to have been for the Aqua Julia, being on high ground, may have been for this branch, which conveyed water to the Thermæ of Titus.

X. SABATINA TRAJANA.

Great works for the aqueducts were carried on in the time of Trajan. One great work of his time was to bring water from the lake Sabatina to the top of the Janiculum. Augustus had previously brought water from that lake, supplementary to his aqueduct, from the lake Alseatina (VII.), to supply his Naumachia in the Trastevere; but the Aqueduct of Augustus was on the lowest level, that of Trajan on the highest. It does not appear that Trajan made use of the old _specus_ of Augustus; but his aqueduct was afterwards made use of by the engineers of Pope Paul V. for the Aqua Paola, although they also brought a branch to it from the Alseatina, as Augustus had done.

That of Trajan is chiefly subterranean, and has been described under the head of the Alseatina (VII.), but nearer Rome it is above ground, and is carried on an arcade against the wall of the Villa Pamphili-Doria, near the Porta di S. Pancratio. Both the arcade and the _specus_ are faced with the _opus reticulatum_ of that period. (664* is from a drawing, 1065 from nature.) In some parts, one side of the _specus_ has been cut away (1063). Just on the outside of that garden a large _castellum aquæ_ of this aqueduct has

been made into a farm-house, and in the yard of that house a branch from it can be seen (665*), apparently for the purpose of irrigation; or, as some think, this was formerly the point of division, one branch going to the Vatican, the other to the great fountain on the Janiculum (960), above S. Pietro in Montorio. The division now takes place at a short distance from this point. Procopius, writing in the sixth century, admires the enormous quantity of water brought by this aqueduct to the highest point in Rome; as it descends the hill, it turns the wheels of the flour-mills. After it arrived at the low level of the ground in the Trastevere, the respirators of the pipes for this aqueduct are carried in tall pyramids resembling chimneys (540). Part of the arcade and _specus_ rebuilt by Paul V., near the garden before mentioned, is shewn in 1064, with the inscription of A.D. 1609 above it.

XI. HADRIANA (?), TRAJANA (?) OR ALEXANDRINA (?).

The next great work of the period of Trajan or of Hadrian, on the eastern side of Rome, was probably begun in the time of Trajan. It brought water from springs under Labicum, now La Colonna, the same that is now brought for the Aqua Felice. The water from several springs was collected in a central reservoir, on which an inscription of Hadrian was found by E. Q. Visconti in the eighteenth century. This is between Pantana and Gabii, in the valley under La Colonna (1540). There are several other reservoirs of the time of Trajan or Hadrian along the line (1637, 1638). This aqueduct was considered by Fabretti to be of the time of Alexander Severus, and since his time it has usually been called the Aqua Alexandrina. It may have been partly rebuilt and brought into use again in his time, after having been choked up with stalactite, one of the springs used proving to be a petrifying spring.

Near the sources this arcade is low and much damaged, and the _specus_ where it remains is nearly filled up with stalactite (1541, 1542). In some parts of the line the stalactite has all the appearance of a petrified cascade, and is evidently formed by the water oozing out and dripping and petrifying as it fell (1436). Further on there is a fine arcade for it across the country in the direction of Cento-Celle; and in some places the arcade is double to raise the _specus_ to the necessary level, as in the Arches of Nero (1428, 1429). A portion of the arcade, where it is broken off, is seen in 1427, with the tower of Cento-Celle in the distance. Another portion of this fine arcade is shewn in 1640. It is of two periods; the upper part is of the third century, and may have been rebuilt by Alexander Severus (as has been said). At Cento-Celle the ground is high, and the aqueduct passes underground for some distance, along the side of the road towards Rome.

About a mile nearer to Rome, there is a branch aqueduct from the foot of the Marcian arcade, in the direction of the Mausoleum of S. Helena, which Fabretti considers as part of the same aqueduct; but it is difficult to see upon what grounds. There is a fine arcade here also for about a quarter of a mile; but it is of the time of Constantine, and I have not been able to trace any connection between this and the other. This arcade has been originally double, and the lower one only now remains, with a modern _specus_ made upon it (555 and 556); but the water now flows _from_ the Marrana, at the foot of the arcade of the great aqueducts, which were here on higher ground, and _runs down_ upon this arcade to the garden and small monastery of S. Peter and Marcellinus, at the Mausoleum of S. Helena, called the Torre Pignattara, from the earthenware pots of which the vault was made.

XII. AURELIA, A.D. 185, AND XIII. SEVERIANA, A.D. 190.

These two aqueducts were made to convey water to the Thermæ of Commodus and Severus in Regio I., of which the remains were found in the excavations of 1870, just within the Porta Latina. The first part was originally made by Marcus Aurelius, for the use of his great villa on the Via Appia, called the Villa dei Quintilii, and the great reservoir and thermæ connected with it remain (2346, 2349, 2350, 2351, 2352). From thence it was brought into Rome by his successor, Ælius Aurelius Commodus. The water came from the Alban hills, near Marino (2358, 2359, 2360, 2361, 2362, 2363), at first underground, and then on an arcade, of which there are considerable remains near the Torre di Mezza Via di Albano (1626 and 1627).

From the Villa dei Quintilii it went parallel to the Via Appia. One of the reservoirs of it nearer to Rome is made into a farm-house, with a tower to it, and has the appearance of a church at a little distance; it is called the Casale di S. Maria Nuova (2348); it then passed again underground. Near the head of the valley of the Caffarella there remains a _piscina_ for it nearly perfect (1372); this is very near also to the Circus of Maxentius and his son Romulus. There is another _piscina_ or small reservoir for it near the church of S. Urbano, often mistaken for a tomb; here it again forms an angle, and the _specus_ descends (plan and drawing, 831*) to the Nymphæum, or so-called Fountain of Egeria (262). The _specus_ is then continued in the cliff of the valley of the Caffarella, from that fountain towards the tomb of the first century called Dio Ridicolo. Nearly opposite to that tomb the _specus_ is visible in the cliff, with large openings into it, between which it passes underground. Wherever it was above ground it has been carried off as building materials and destroyed, so that it has not again been found until it arrives at the remains of a _piscina_, just to the south of the Porta Latina (984). It then entered the city of Aurelian through the bank on which his wall is built, and supplied the Thermæ of

Commodus within that gate (as has been said), 1485, 1486.

XIV. ANTONINIANA, A.D. 215.

This aqueduct was used to supply the great Thermæ of the Antonines, now called after Antoninus Caracalla. It is more easily traced backwards, passing along the inner side of the bank on which the Wall of Aurelian is built, then upon an arcade which has been destroyed in this part, but of which remains are visible inside of the Porta Ardeatina (986), by the side of the Arch of Drusus, just within the Porta di S. Sebastiano (73, 1772, 1202). It then passes underground through the bank, and emerges in the city wall at the angle between the Porta di S. Sebastiano and the Porta Latina (539, 883). It here crosses the road, and is visible in the garden on the opposite side (884).

XV. ALEXANDRINA, A.D. 225.

The Aqua Alexandrina is mentioned by Lampridius in his life of Alexander Severus, but it was probably a branch from the Anio Novus only, as the Nymphæum engraved on one of his coins[230] has been identified with the ruins near S. Maria Maggiore (2126, 2127). This stands on very high ground, and the only aqueduct that could reach it was that of the Anio Novus. This branch can be traced in the wall by the piers of the arcade, which have been built into the Wall of Aurelian near the Porta Maggiore (80 A, B). The _specus_ and the arches were destroyed by the engineers of the Aqua Felice; the piers only remain, and these cease just before we arrive at the point where the railway now enters Rome through the wall (99). They come to an end directly in a line with a large reservoir, now a gardener's house, near the Minerva Medica, almost between that and the wall, but a little to the south of it; one pier, however, of the tall arcade of the third century remains, as a sort of buttress, against that side of the fine building of the same period called the Temple of Minerva Medica (537). There are great remains of thermæ and fountains in the large vineyard in which this building stands. Some of these are of an earlier period; but a considerable part of them are of the third century, and of the time of Alexander Severus. The Nymphæum before mentioned was at the north end, and is a fine picturesque ruin, with very evident remains of the aqueduct in it (61, 963, 964). The water was here divided into several branches, of which we see portions of the _specus_ going in different directions. One of the most important of these goes to the great reservoir of the Thermæ of Titus and Trajan, called the Sette Sale. This was made long before the time of Alexander Severus, who only rebuilt the Nymphæum; and there is an arcade of the first century leading to this Nymphæum from a reservoir near the Porta di S. Lorenzo.

At a short distance to the south of this celebrated Nymphæum is another very curious reservoir, now in a very bad state, having been turned into a gardener's house, but which must have been of considerable importance, and probably belonged to the thermæ of the third century (2322, 2323). There is a _cippus_ with an inscription, which indicates that the building was a _castellum aquæ_ (2324).

XVI. ALGENTIANA, A.D. 300.

This aqueduct was made to supply the great Thermæ of Diocletian on the Viminal Hill, but is believed to have been entirely subterranean, so that little is known about it. There was a reservoir for it on the eastern side of the Thermæ, under the present railway station. Drawings and a plan of this were preserved by Visconti[231].

XVII. THE AQUA CRABRA, THE MARRANA, A.D. 1124, AND THE RIVER ALMO.

These three may all be treated as one aqueduct for the supply of Rome, partly natural and partly artificial. They all come from the Alban Hills; the first from near Rocca di Papa on very high ground, the second from about a mile above the small and very picturesque town of Marino; the third lower down the same hill. They are all mountain streams, and partake of the usual character of such streams; in dry weather the springs that supply the Almo bring so little water, that it is only sufficient to fill some ponds for cattle at the foot of the hill. The deep bed of the river, which winds about the Campagna for miles, is therefore dry for a great part of the year, but the other two streams never fail; they are united at the foot of the hill, not far from the place where the Aqua Aurelia came from. The greater part of their united waters runs into the river Anio, but a portion of it is diverted near the ruins of the ancient fortified village or _pagus_, called _Centroni_ (2315, 2316, 2317, 2318, 2319), on the road to Tusculum, (now Frascati,) about eight miles from Rome. This branch to supply Rome is first brought through an ancient tunnel of the Aqua Julia, at each end of which remains can be seen of the stone _specus_ and the flood-gates (2310, 2311, 2312, 2313). The water is then conveyed in a bank of clay for about a mile, and then in the bed of one of the many branches of the mountain stream called the river Almo, and so brought into Rome (1309, 1318), under the Porta Metronia, which is built upon a bridge over it. The stream passes under some other

bridges with mills upon them, and eventually falls into the Tiber through an aperture left for it in the Pulchrum Littus, or fine tufa wall of the Kings (drawing, 1235*; plans, 368*, 1234*; views, 77, 166, 157).

Another branch from it is carried from the junction or separation between the Torre Fiscale and Roma Vecchia (1937*) by the side of the cross road from the Via Appia Nova to the Via Appia Antiqua. Sometimes in the bed of the Almo, and in other parts, where the ground is low and the stream is liable to floods, an artificial canal is made for it, which may be seen in the valley of the Caffarella. This excellent plan was carried out in the most economical but effectual manner by a company in the twelfth century. This is really an aqueduct, though not usually so called; it is kept in repair by the present Water-Company, and is of great importance for Rome; as the floods to which the Almo was always liable along its whole line, and within the walls of Rome, (as is mentioned by Cicero,) are effectually kept out of Rome, and a constant, regular supply of water is obtained.

XVIII. AQUA FELICE, made A.D. 1587 by Pope Sixtus V. (Felice Peretti).

The sources of it are the springs under the hill on which La Colonna stands. The same water had been used long before, and brought into Rome by the aqueduct (XI.) of Hadrian and Trajan before mentioned. The large reservoir for the water now in use is very near to the remains of the old one of Hadrian. The construction of this aqueduct is very rude and rough, of concrete and rubble-stone only, and this stone consists entirely of old materials; still the large scale of the work, and the height at which the _specus_ is carried upon the arcade, give it a grand effect. At a little distance, the inferior construction is not seen, and this almost modern aqueduct is frequently mistaken by strangers for one of the old ones of the time of the Empire, of which it is only an imitation. It is seen in several of the views of the older aqueducts in the Campagna, especially those at the Torre Fiscale (531, 1028, 1029) and the Porta Furba (68, 1437). Here it crosses the road to Frascati on an arch, with an inscription upon it. In the latter part of its course it is made on the piers of the Claudian arcade, and it enters Rome at the same point, the north-east corner of the gardens of S. Croce. After passing along the north side of them, it is divided into different branches by a reservoir at the angle, close to the south side of the Porta Maggiore (30). The principal stream then passes along upon the Wall of Aurelian (80 A, B, 81), on the same high bank as the earlier aqueducts had done; it was cut through in making the railway, but a new bridge over that road was built for it (29). Near this it can be seen that it is carried on the piers of an older aqueduct for some distance (28). See Alexandrina (XV.)

Further on towards the Porta di S. Lorenzo the ground is higher, and in order to keep the level necessary for the _specus_, it is brought within the wall, and built up against the inside of it (1871). The Marcia, Tepula, and Julia, over which it is carried, as is seen at the two gates where their arcade is visible _under_ the _specus_ of the Aqua Felice, are here still under it, but _underground_ also, owing to the higher level of the ground. It passes over the Porta di S. Lorenzo to a reservoir on the north side of it, and then turns to the west by the side of the road, which it crosses upon an arch, with an inscription upon it, at a short distance within that gate (81). The principal termination of it is at the Fountain of the Termini (called of Moses,) 71. Behind the fountain is a reservoir after the old fashion, which is illustrated by a plan and section (704*). The celebrated Fountain of the Triton (1196), in the Piazza Barberini, is also supplied by this aqueduct, as well as all the upper terraces upon the hills. The lower range, on the Campus Martius, is chiefly supplied by the Virgo. Another branch goes from the reservoir at the Porta Maggiore along the bank on which the Arches of Nero are carried, to the Lateran, where the fountains are supplied by this water. The old aqueduct was used according to the custom of the time, and there is a cascade _specus_ from the level of the Marcia to that of the Appia (shewn in 541).

The _specus_ of each of these old aqueducts was used to carry the metal pipes of the Aqua Felice, when it was convenient to do so (1295*), as has been previously mentioned.

THE AQUA MARCIA PIA was made by a Company between 1860 and 1870, and has been mentioned under the head of the Marcia (a part of it is shewn in 1553).

THE AQUEDUCTS.

ANIO NOVUS.—THE RIVER ANIO.

DESCRIPTION OF THE PHOTO-ENGRAVINGS.

PLATE I.

[Illustration: AQUEDUCTS—SOURCE OF AQUA APPIA.

ANCIENT QUARRY OF THE KINGS.]

Source of the Aqua Appia, in a very ancient Stone-quarry of the time of the Kings, in the meadows on the bank of the river Anio, formerly called the meadows of Lucullus. They are not far from Lunghezza, the site of the ancient city of Collatium. This cave has two springs of water in it, and the two streams meet at the mouth of the cave in a channel, which is at first open at the top, and crosses the low meadow with the appearance of a ditch only, to a central reservoir, also in a cave, from which the tunnel _specus_ begins that runs on, into and through Rome. Three streams meet at the same central reservoir, and their united water goes through the _specus_. Each _specus_ can be traced by the line of bushes in the meadows, each bush being over one of the wells; these descend at regular intervals into the _specus_. These wells are also called respirators or ventilators, as they give air to the current of water, or as the people say, enable it to breathe. This cave is easily overlooked, and any person passing on the higher ground over it, is almost sure not to see it. It is scarcely visible until close to it. The ancient quarry from which it comes is earlier than others in the neighbourhood. The celebrated Caves of Cervaro are also ancient quarries; they are about a mile from this point, and although very early, are not quite so early as this, which is more distant from the river Anio. It seems probable that this was one of the quarries for the city of Collatium, before the time of Servius Tullius.

PLATE II.

[Illustration: AQUEDUCTS—SOURCE OF AQUA APPIA.

ANCIENT QUARRY OF THE KINGS.]

SOURCE OF ANOTHER SPRING OF THE AQUA APPIA, in another ancient stone quarry on the bank of the river Anio. This is one of a fine series of ancient quarries, now caves, about a mile higher up the river than the Caves of Cervaro. These are believed to have been the quarries from which the large blocks of tufa for the walls of the Kings of Rome were taken, especially the great wall of Servius Tullius, which was a mile long, fifty feet high, and in some parts twelve feet thick, and which would require an enormous quantity of stone. This was probably floated down the Anio on wooden rafts, which served for timber also. The pool at the source of this spring appears as if it came from the water dripping through the rock above, which serves for a roof; but the old shepherds, who have watched it for years, say that the water never fails, and that it is a natural spring, although the quantity of stone refuse thrown into it makes it impossible to see exactly where it rises. These caves are extremely picturesque, more so even than the Caves of Cervaro, though these are the favourite resort of the German artists in their annual festival.

PLATE III.

1. THE AQUEDUCTS ABOVE SUBIACO.

2. RIVER ANIO, THE UPPER LOCHS.

—— THE THIRD LOCH AND THE BRIDGE.

[Illustration: AQUEDUCTS ABOVE SUBIACO

RIVER ANIO THE UPPER LOCHS

THE THIRD LOCH AND THE BRIDGE]

The water for the aqueducts of Rome was chiefly drawn from the river Anio, or from springs or tributary streams that fell into that river. It rises in the high mountains above Subiaco, which are generally covered with snow for the greater part of the year, and the supply of water never fails entirely, though it is not always equally abundant. It is generally a clear, bright mountain stream, coming through rocks, but it is liable to sudden and violent floods, which bring down a great deal of mud, and therefore great precautions are taken for filtering it. The latest and most important of the great aqueducts were the Claudia and Anio Novus; the latter was the most abundant of all, being in fact a branch of the river compelled to pass through Rome by clever engineering. A series of great lochs was made by building dams across the river, with cascades from one to another. There were three of these about two miles above Subiaco, and about forty-two miles from Rome. The uppermost one of them is seen in the upper part of the plate, but in the third loch, the lowest of the three (shewn in the lower part of the plate), the bed of the river is so deep, that the water is not seen. The country through which it passes is celebrated as among the most beautiful in Italy.

PLATE IV.

[Illustration: AQUEDUCTS ABOVE SUBIACO

ANIO NOVUS, THE THIRD LOCH

ANIO NOVUS, SPECUS CUT IN THE CLIFF]

1. ANIO NOVUS, THE THIRD LOCH, as seen from below, where the dam, that formerly kept up the water and formed a great cascade, has been thrown down, and appears only as rocks in the stream; the modern bridge seen in this view is built upon the two ends of the old dam.

2. ANIO NOVUS, SPECUS. The _specus_ is here a tunnel cut in the cliff, on the side of the valley on which the town of Subiaco stands; it is six feet high, and only eighteen inches wide (an opening into it may be seen in the cliff, on the left-hand side of the view). The round tower, seen on the right, is that of the Villa Gori, about a mile above Subiaco.

PLATE V.

AQUEDUCTS ABOVE SUBIACO—ANIO NOVUS, CASTELLUM.

[Illustration: AQUEDUCTS ABOVE SUBIACO

ANIO NOVUS, CASTELLUM

LINE OF THE SPECUS OF ANIO NOVUS

Photogravure Dujardin, Paris]

This is the loch below the modern bridge, which is made upon the remains of the old dam across the river, destroyed in the fourteenth century by making a hole at the bottom to let the water escape from a flood in the upper country. The force of the water once let loose soon destroyed the dam, and the large stones of which it was built are still lying as rocks in the river, and are seen in the photograph and the photo-engraving.

LINE OF THE SPECUS OF THE ANIO NOVUS. It is here carried in the cliff of the valley of the river Anio, seen on the left of the picture. Both of these views are continuations of those seen in Plate IV., and one helps to explain the other. The _specus_ continued in this way for many miles underground, in one sense, when seen from above, but not underground when seen from below. When it has to cross the mouths of the small subsidiary streams that fall into the Anio, it has to be carried over bridges or arches, at other times it is cut in the rock or cliff.

PLATE VI.

THE CLAUDIA, ANIO VETUS, AND NOVUS, AND MARCIA IN THE VALLEY OF THE ARCHES ABOVE TIVOLI.

[Illustration: AQUEDUCTS—CLAUDIA AND ANIO-NOVUS.

IN THE VALLEY OF THE ARCHES, NEAR TIVOLI.]

This valley is about two miles above Tivoli, where there is a junction of another stream with the Anio, in rather a wider valley than the usual valley of the Anio only. One arch of the lofty Claudian arcade is left on the side of the valley next Tivoli, and on the top of this a medieval tower has been built, which has an extremely picturesque effect. Through the arch may be seen a small portion of the Marcian arcade, and at a few yards to the left the Anio Vetus, which there passes half-underground at the foot of the tall arcade of the Anio Novus.

PLATE VII.

[Illustration: AQUEDUCTS ABOVE TIVOLI

ANIO NOVUS. MEDIEVAL TOWER

IN THE VALLEY OF THE ARCHES

Photogravure Dujardin, Paris]

TWO OTHER VIEWS OF THE RUINS OF THE ARCADES OF THE CLAUDIA AND ANIO NOVUS, in the Valley of the Arches above Tivoli. In the foreground, the Marcian seen through the arch, and the Anio Vetus again through the arch of the Marcian. These views are celebrated for their picturesque character, as indeed is all the country about Tivoli and Subiaco.

PLATE VIII.

AQUEDUCTS AT TIVOLI. CASCADES OF THE ANIO, WITH THE ROUND TEMPLE OF THE SIBYL AT THE TOP.

[Illustration: AQUEDUCTS AT TIVOLI

TEMPLE OF THE SIBYL AND CASCADES

CASCADES OF THE ANIO]

This cascade shews the character of the country through which the aqueducts had to be carried, but the waters of the aqueducts taken out of the river Anio were necessarily confined each within its own _specus_, here in tunnels, which are carried in a zig-zag course gradually down the hill to the level of the Villa of Hadrian in the valley below.

PLATE IX.

AQUEDUCTS BELOW TIVOLI.

[Illustration: AQUEDUCTS BELOW TIVOLI

MARCIA ON THE VIA DI CARCIANO

MARCIA CASTELLUM. B. C. 145]

THE MARCIA, A GREAT CASTELLUM AQUÆ OR RESERVOIR ON THE VIA DI CARCIANO. This is sometimes called the “Promenade” of Carciano, being a favourite walk on the brow of the hill, from which there is a distant view of S. Peter’s at Rome. This fine reservoir (of which two sides are here shewn) is of the time that this aqueduct was made, B.C. 145. It was probably from this reservoir that a branch _specus_ descended to the Villa of Hadrian below, to which there is a bridle-road from near this point.

PLATE X.

AQUEDUCTS BELOW TIVOLI. AQUA MARCIA, RESERVOIR.

[Illustration: AQUEDUCTS BELOW TIVOLI

AQUA MARCIA RESERVOIR

RESERVOIR OF AQUA MARCIA INTERIOR]

This is another of the great reservoirs to receive and retain a supply of water on the edge of the hill, both as one of the many such reservoirs for the supply of water to Rome, and for the purpose of local irrigation. It consists of two large chambers, divided by an arcade, which is the usual plan, and is probably part of the original construction of B.C. 145. These reservoirs are remarkably picturesque and finely situated.

PLATE XI.

AQUEDUCTS BELOW TIVOLI. ANIO NOVUS, CASTELLUM.

[Illustration: AQUEDUCTS BELOW TIVOLI

ANIO NOVUS, CASTELLUM

MARCIA, CASTELLUM OF TRAJAN]

This is another of these fine reservoirs, about a mile further on; it is faced with the reticulated-work of the first century, and is part of the original work of the time of Nero.

MARCIA, CASTELLUM OF TRAJAN, who repaired the aqueducts in several places, as is recorded by inscriptions. The reticulated-work with which this is faced is very peculiar, and is believed to be unique, at least it has not been observed elsewhere.

PLATE XII.

THE CLAUDIA AND ANIO NOVUS IN THE CAMPAGNA OF ROME, NEAR ROMA VECCHIA.

[Illustration: THE AQUEDUCTS. CLAUDIA AND ANIO NOVUS

IN THE CAMPAGNA NEAR THE PISCINAE AND ROMA VECCHIA.]

This grand arcade is the most perfect part of this finest of the aqueducts, and extends for about a mile, from near the farm-house called Roma Vecchia, about four miles from Rome, to the piscinæ where the arcade becomes gradually lower as the ground rises towards the foot of the hills. The two _specus_ are clearly seen with their usual characteristics, the Claudia built of large squared stones; the Anio Novus is visible, faced with brick in most parts, but here is faced with reticulated-work. In the first part of this view are seen the ruins of one of the enormous reservoirs, or Castella Aquarum, at one of the angles which occur at each half mile along its course. The object of these very numerous reservoirs probably was two-fold, one for local irrigation, the other for keeping up a constant and never-failing supply for Rome, even in the hot season, when many springs cease to flow.

PLATE XIII.

[Illustration: AQUEDUCTS ON THE VIA LATINA.

NEAR PORTA FURBA

UNDER THE TOR FISCALE MARCIA & CLAUDIA

Photogravure Dujardin, Paris]

THE MARCIA, TEPULA and JULIA passing under one of the arches of the CLAUDIA and ANIO NOVUS, now under the TOR FISCALE. A medieval tower built upon the celebrated crossing of the aqueducts, where seven aqueducts crossed each other at different levels. The Anio Vetus passes under it just underground, and the AQUA FELICE by the side of it. The _specus_ of the Aqua Marcia, built as usual of squared stone, is seen upon the arch that carried it; the others are concealed by a modern wall, but can be traced passing under the stone arch of the Claudian. The other view in the upper part of the plate shews another crossing, at one of the angles made to break the force of the water. The Marcian and the Claudian arcades running parallel to each other at a short distance only, the angle of this goes across the intervening space, and then changes sides for a time. The road which here runs between the two arcades passes under the arches at both ends of this junction, near the Porta Furba, which is seen in the distance. The character of the brickwork of the arch in the foreground indicates the time of Trajan, with later repairs, which were made at all periods in this arcade.

PLATE XIV.

[Illustration: AQUEDUCTS

MARCIA AT PORTA TIBURTINA

CLAUDIA AND ANIO NOVUS AT ANGLE OF THE SESSORIUM]

The upper view represents the stone _specus_ of the Aqua Marcia at the PORTA TIBURTINA, now of S. Lorenzo, just within the gate, and in the wall on the southern side, with an opening by the side of it, through which a man can now walk into the _specus_ and along it. To the right of this, still in the wall, is a Castellum of the Aqua Felice, which is here, as at the Porta Maggiore, above the Marcia, Tepula and Julia, and below the Claudia and Anio Novus.

In the lower view is the Claudia and Anio Novus, at the north-east angle of the gardens of the Sessorian Palace (now of S. Croce in Gerusalemme). One of the stone piers of the Aqua Claudia is seen just within the projection of the tower at the angle, which is an addition of a later period. Within this portion of the City wall is a great Castellum Aquæ, extending from the corner to the tower, through which the aqueducts entered Rome. The interior of the tower is a piscina, which is shewn in another plate.

PLATE XV.

AQUEDUCTS AT THE PORTA MAGGIORE. THE MARCIA, TEPULA, AND JULIA ENTERING ROME.

[Illustration: AQUEDUCTS AT THE PORTA MAGGIORE.

MARCIA TEPULA JULIA ENTERING ROME

MARCIA ETC. WITHIN THE WALL.]

The upper view shews the exterior of the wall, with the three _specus_ passing through it, under an arch of the Claudian arcade, now destroyed. These are carried upon one of the piers of the Marcian arcade, built of squared stone, as the part near Rome always was. In the left lower corner of this view may be seen the Anio Vetus, half underground, as usual for this aqueduct. [This opening has been built up since the photograph was taken. The demolition of all traces of the old aqueduct as far as possible was part of the plan of the architect, who directed what were miscalled the _restorations_ of the City wall.]

The lower view represents the _specus_ of the Aqua Marcia, of squared stone, carried on one of the arches of the Marcian arcade through the wall, within it at the same point as that of the exterior shewn above.

PLATE XVI.

CLAUDIA AND ANIO NOVUS.

[Illustration: AQUEDUCTS

ANIO NOVUS ON THE CAELIAN

CLAUDIA AND ANIO NOVUS OVER THE PORTA MAGGIORE]

I. OVER THE PORTA MAGGIORE. In the lower view the two _specus_ are seen endways, built of squared stone, as part of the gateway. The point of view for this is nearly the same as that of Plate XV., looking south instead of west. The curious tomb of the Baker Eurysaces is seen on the left, with the stone kneading-troughs of which it is built.

II. The upper view is one corner of the great reservoir of Nero on the Cœlian, near the west end, over the Arch of Dolabella, which is seen built of well-cut stone, and perfectly plain. This has an inscription, with the names of the Consuls of the time of Augustus (A.D. 10), forty years afterwards; the arch, which was the eastern entrance into the Claudium, was used by the engineers of Nero as a substructure for the corner of the great reservoir of water for the supply of that part of Rome, which was carried at the height of thirty feet from the ground. Some small square windows are seen in the wall, which belonged to the chapel of S. Thomas _in formis_ (or in the arches), made in the remains of the arcade in the eighth century, and removed in the twelfth for a larger chapel, now in the garden of the Villa Celi-montana near to it. At the left-hand corner of this view is seen the gateway of the small monastery of the Redemptorists, with the celebrated mosaic picture over it, representing Christ between a black and a white slave, shewn in another plate of this work.

PLATE XVII.

ARCHES OF NERO WITHIN THE PORTA MAGGIORE.

[Illustration: AQUEDUCTS. ARCHES OF NERO.

WITHIN THE PORTA MAGGIORE.

AQUA MARCIA, WITHIN THE PORTA MAGG: 1871.]

This double arcade crosses the valley or inner foss of the Sessorian Palace. It was built on this plan for greater strength, as the piers are of a great height. This arcade is a continuation of the one that forms the northern wall of the Sessorian gardens, in a direct line to the west, over the Cœlian to the great reservoir over the Arch of Dolabella (shewn in the last plate). The _specus_ was carried at the top, and conveyed the water of the Claudian and Anio Novus, _united_ at _the Gemelli_ (a great twin reservoir which was close to that point, and at the north-west angle of the Sessorian gardens). The Claudian as a separate water turns at a sharp angle, and goes on to the Porta Maggiore, with the Anio Novus over it, and terminated at another tower just to the north of the place where the Marcia, Tepula, and Julia pass through the wall. But they left a considerable part of their water at that angle to be united to that of the Anio Novus at the Gemelli.

The lower view represents a fragment of the Aqua Marcia, as repaired and restored by Trajan, to the north of, and near the Porta Maggiore, in the vineyard in which the Minerva Medica stands, which has been the Exquiliæ, and afterwards the gardens of Mæcenas. This, which is parallel to the City wall, is joined to it a little further on. It was accidentally brought to light by some excavations in 1871, and is now buried again.

PLATE XVIII.

THE CLAUDIAN AND THE ANIO NOVUS, IN THE NORTH WALL OF THE SESSORIAN GARDENS, NEAR THE PORTA MAGGIORE.

[Illustration: AQUEDUCTS NEAR PORTA MAGGIORE.

CLAUDIA AND ANIO NOVUS IN THE WALL OF THE SESSORIUM.

NYMPHAEUM OF ALEXANDER SEVERUS WHERE THE TROPHIES OF MARIUS WERE HUNG.]

The wall for about a quarter of a mile is entirely made out of this arcade, with the arches filled up, but it is built upon the old earthwork of the Sessorium, probably of the time of the Kings. The arcade extends from the angle at the north-east corner, where the aqueduct entered Rome, to the north-west angle near the Porta Maggiore, which was called Porta Sessoriana, because it entered into the Sessorian gardens.

The lower view represents the NYMPHÆUM OF ALEXANDER SEVERUS, WHERE THE TROPHIES OF MARIUS WERE HUNG.

This is identified by a representation of it on one of the coins of that Emperor. It is commonly miscalled a Castellum of the Aqua Julia, but it is on too high a level for that water, and there is no other but the Anio Novus which is high enough; this was brought along the wall to another reservoir near the Porta Tiburtina, and then by a branch arcade to this point, where there is another large reservoir on high ground, from which the water was dispersed in different directions. One branch went to supply the great reservoir called the _Sette Sale_, which supplied the Thermæ of Titus and Trajan on the Exquiliæ, and from thence went on to the Colosseum and to the Tiber. Another branch supplied the Thermæ of Constantine, on the Quirinal.

PLATE XIX.

RESERVOIR ON THE ARCHES OF NERO OVER THE ARCH OF DOLABELLA.

[Illustration: AQUEDUCTS—ON ARCHES OF NERO.

OVER THE ARCH OF DOLABELLA]

This Plate is almost a repetition of Plate XV., but from a different point of view, and this great reservoir is of so much importance for the history of the aqueducts in Rome, that it was necessary to shew it as clearly as possible. Without repeating what has been said before, we may add that the arch seen to the right in this view is the beginning of an arcade which led to the Colosseum. Another branch in a more direct line led to the Palatine, after passing first along the north wall of the garden of the Villa Celimontana, then by the western side of the Clivus Scauri, parallel to the church of SS. John and Paul, and at the foot of the hill passing across the road, and under the apse of the church; then turning again southwards on an arcade across the valley to the Palatine, of which there are remains; afterwards passing along the whole length of the Palatine underground, it is visible at the mouth of a tunnel on the platform opposite to the Capitoline Hill, and went across the Forum Romanum over the bridge of Caligula. The work of Nero stopped at the Arch of Dolabella, but it was taken up and completed by his successors.

Another branch went also to the left, on the west wall of the garden of the Villa Celimontana, to the valley between the Cœlian and the Aventine. There is a large reservoir for it on the cliff of the Cœlian, partly below and partly above it, and in the garden of the monks of S. Gregory. It then went on a tall arcade, over the Porta Capena and the _agger_ of Servius Tullius, to the Piscina Publica, and from thence, again crossing the valley between the two parts of the Aventine, to the Thermæ of Sura, and the private house of Trajan, and the temples on the edge of the Aventine, and to the mouth of the aqueducts in the cave under the Priorato at the Porta Trigemina, and so to the Tiber.

DESCRIPTION OF THE DIAGRAMS.

PLATE II.

[Illustration: II.

AQUEDUCTS—AQUA APPIA, SPECUS.

IN A TOWER OF THE PORTA CAPENA, UNDER THE CŒLIAN, NOW A GARDENER'S COTTAGE, EXCAVATED IN 1868.]

THE APPIA (I.) at the PORTA CAPENA, in the eastern tower of the gate, now in the house of the gardener of the monks of S. Gregory. The _specus_ is built of large blocks of tufa, and the lower part of it cut in the tufa wall of Servius Tullius; it was distinctly visible in the excavations of 1870, when this drawing was made. The line of the aqueduct upon the short _agger_ between the Cœlian and the Aventine was also visible for several yards, and in three different places, where pits were dug fifteen feet deep, the last was where a branch was carried into the Piscina Publica. The middle pit was in waste land on the western side of the present south road through the gate of S. Sebastian, or the modern line of the Porta Appia. It was to this pit that his holiness Pius IX. was taken to see it by the Cavaliere Guidi, and he said there was no denying that this was part of the wall of Servius Tullius, but he was surprised that his Roman friends had not discovered this. The greater part of the pits that he opened might have been left open, if it had not been for the prejudices of the subordinate officers of the Government. The particular pit in question was in waste ground by the side of the road, and might have been left open without any inconvenience.

PLATE III.

[Illustration: III.

AQUEDUCTS—AQUA APPIA, SPECUS.

IN A STONE QUARRY UNDER S. SABBA, ON THE AVENTINE, WHERE SEVEN BRANCHES OF LATER AQUEDUCTS CAST THEIR SURPLUS WATER INTO THE APPIA, EXCAVATED IN 1868.]

The Appia (I.) under S. Sabba, in an old subterranean stone quarry. Several branches of other and later aqueducts here cast their surplus water into the _specus_ of the Appia, the earliest and the lowest (as shewn in the plan). The _specus_ is also visible in several places, filled up to one-third of its depth by the deposit of clay left by the water, which comes from swampy meadows on the bank of the river Anio, in which the soil is clay, upon tufa rock, called the "Meadows of Lucullus."

Over the plan in this plate are two sections of the _specus_; in the one to the right the clay deposit left by the water is shewn, in the one to the left a small pipe coming into the _specus_, probably part of the system of irrigation, which was one great use of the aqueducts; the green lines winding through the quarry represent the lines of the various streams of water coming at different levels, sometimes with a very rapid descent, and all falling into the old deep _specus_ of the Appia, before that was carried across the last road that it had to pass. In this instance it was probably carried under the road, and not over the arch of the gate. At this point four roads meet, which is almost a certain indication of the site of a gate. In most cases the _specus_ was carried over the gate, but here the level seems too low, unless the old foss-way has been filled up even more than the usual fifteen feet. The _specus_ is

visible again in another subterranean stone quarry under S. Prisca, in the same large vineyard formerly of the Jesuits, now of Prince Torlonia, in which, at a higher level, are also the remains of the Wall of the Latins on the Aventine, and of the Thermæ of Sura and the private house of Trajan. Another aqueduct passed over this to supply the Thermæ; this is on a very high level, and was carried on a tall arcade across the valley, from the Cœlian to the Aventine, passing over the Porta Capena and on the old _agger_. There are remains of the tall brick piers in several places, and of the arcade and _specus_ on the hill near S. Prisca, visible from the Palatine.

PLATE IV.

[Illustration: IV.

AQUEDUCTS—AQUA APPIA, MOUTH.

IN A CAVE OF THE AVENTINE, UNDER S. ALEXIO, AT THE PORTA TRIGEMINA, NEAR THE MARMORATA, EXCAVATED IN 1868.]

Mouth of the Appia (I.), in a cave under the Priorato or Priory of the knights of Malta on the Aventine, near the Marmorata and the Porta Trigemina. At the back of the cave, and connected with it by a natural tunnel, is a large reservoir of water in the heart of the hill, supplied by a natural spring, which was added to the water brought by the aqueduct for distribution. The latter part of this cave, behind the part here shewn, is under the garden of the monastery of S. Alessio, and the cave belonged to those monks. A plan and section of it is given in another plate. In the inner part of the cave is the natural spring, so that it is always knee-deep in water. This seems a likely place to have driven cattle into for concealment; there is no other natural cave under the Aventine, and this is close to the Porta Trigemina. The idea that there was a cave near the Forum Boarium seems to have arisen from a misunderstanding as to the exact site of the Porta Trigemina, which was supposed to be close to that Forum, instead of being a quarter of a mile from it, and close to the Sublician, or wooden bridge, where some remains of it have been found. The _specus_ of the Aqua Appia leads directly into this cave, and other aqueducts also meet there. The surplus water of the Trajan, far above this level, descends into it by a vertical pipe of terra cotta. Piranesi, in the last century, recognised the cave as the mouth of the Aqua Appia, and gives one of his admirable etchings of this part of the Aventine, with the cave at its foot. He was in advance of his time, but a great deal of fresh evidence has come to light since that period.

PLATE V.

I. AQUA APPIA.

[Illustration: V.

THE AQUEDUCTS.—APPIA.

RESERVOIR IN THE GARDEN OF THE SESSORIUM, NOW OF S. CROCE, CALLED THERMÆ OF S. HELENA.

A. SECTION. B. PLAN.]

The Aqua Appia (I.) is at so great a depth near the Porta Maggiore (which stands on very high ground), that it is difficult to trace it, but the _specus_ was found in making the railway in a deep cutting about half-a-mile outside of that gate, and was described in the _Bulletino di Correspondenza Archæoligia_ at the time it was found. There is reason to believe that it entered Rome under the wall on the north side of the Sessorian Gardens, and was received in a reservoir, of which there are remains at a considerable depth, especially the lower story. This is near the reservoir of the great Basilica or Hall of the Palace, of which the apse remains. The plan and section of this reservoir are shewn in this diagram. The _specus_ from this point turned to the west, and passed along the Cœlian Hill at a low level, nearly under the arches of Nero; but before arriving at these, it passed through another large and deep reservoir to the south of the Porta Maggiore, now in a vineyard, with another large reservoir close to it. These two are believed from the situation to be the Gemelli of Frontinus. An inscription was found on the one in the garden of the Sessorium relating to the Thermæ of S. Helena, who resided in that palace, and probably the water for her bath-chambers was taken from this reservoir.

PLATE VI.

II. ANIO VETUS.

[Illustration: VI.

THE AQUEDUCTS.—ANIO VETUS. RESERVOIR NEAR THE PORTA FURBA.

A. SECTION, SHEWING THE DEPTH UNDERGROUND.

B. PLAN OF THE TWO CHAMBERS AND THE ENTRANCE.]

The reservoir, of which the plan and section are given in this plate, is situated at about a quarter of a mile from the Porta Furba, near the junction of the old Via Latina with the Via Appia Nova. It is just two miles from Rome, and so agrees with the text of Frontinus. It seems clear that at this point part of its water was carried by the Octavian _specus_ to the Porta Maggiore, while the main stream went on along the side of the Via Appia Nova to the Asinian Gardens, just within the Porta Asinaria. It was shewn in some excavations made under my direction in 1871. We had long been looking for it, and the gardener informed us that there was a vaulted chamber under part of that garden or vineyard, where we found it, a few feet underground, and about a hundred yards from the arcade of the great aqueduct on the southern side, nearer to the present road than the reservoir.

PLATE VII.

LOCH IN THE AQUA JULIA, NEAR THE IMPERIAL VILLA, CALLED THE SETTE BASSI (SEPTIMIUS BASSUS?).

[Illustration: VII.

THE AQUEDUCTS.

A LOCH IN THE AQUA JULIA, NEAR THE VILLA CALLED SETTE BASSI. PLAN AND SECTION.

A. SECTION OF THE BRANCH.

B. THE SPECUS.

B. PLAN, SHEWING THE DIVISION AND THE LOCH.

A. A. THE SPECUS.

B. THE LOCH FOR THE BRANCH.]

The Aqua Julia at this point, which is about four miles from Rome, is just underground, and this loch and branch to supply the Villa was discovered about 1850 by Signor Moraldi, when he was making a map of the Aqua Marcia, with a view to having it brought again into use; which has since been done, but by a different line.—To save carrying it so far round as the old aqueduct was carried (in order to avoid the mouths of the many streams that run into the river Anio), the modern engineers used metal pipes in this part. Above Tivoli they built a stone _specus_ after the old fashion, as in that stone country they found it the cheapest and the best plan. They now say they regret that they did not continue the stone _specus_ over the level Campagna also, as the metal pipes are continually bursting from the force of the water. Previous to this discovery of Signor Moraldi, it was not known that there were lochs in the aqueducts, though it is obvious that when branches had to be taken from them, such an arrangement would be required. The Tepula and the Marcia are underground in this part. The Julia, being the uppermost of the three, was close to the surface. This was also the case on the side of the great _agger_ of Servius Tullius near the railway station, where the Julia only was excavated, with two cippi, on which were inscriptions stating that _the three_ aqueducts passed there.

PLATE VIII.

AQUEDUCTS AND RIVER ALMO, NEAR THE PORTA FURBA.

[Illustration: VIII.

THE AQUEDUCTS AND RIVER ALMO, NEAR THE PORTA FURBA.

A. PLAN AT A CROSSING.

B. PLAN AND SECTION AT ANOTHER POINT.

C. PLAN AND SECTION IN THE QUARRY AT THE ALBERGO DE’ SPIRITI.

D. PLAN AND SECTION OF RESERVOIR NEAR THE SAME.]

A. Arcades of the Marcia, Tepula, and Julia; the Claudia and Anio Novus at one of the angles and crossings; and the Aqua Felice, which is carried first on one and then on the other of the old arcades. Also, there is an indication of the situation of the great tumulus and tomb called “Monte del Grano,” in which the fine sarcophagus was found which is now in the Capitoline Museum, and was long supposed to be that of the Emperor Alexander Severus and his wife Mammea. This is given to indicate the situation. The river Almo is seen crossing the two arcades near the gate or arch over the road.

B. The same two arcades, at about a quarter of a mile nearer to Rome, or just two miles, with the river Almo winding between them; and a Section to shew the elevations.

C. Plan of the junction of the old Via Latina, with the modern road to Albano, at two miles from Rome, shewing the situation of the aqueduct in a stone-quarry at the back of the “Albergo dei Spiriti,” near C.

D. Plan and Section of the reservoir, at two miles from Rome, near the Porta Furba.

PLATE IX.

THE SEVEN AQUEDUCTS AT THE TOR FISCALE.

[Illustration: IX.

THE AQUEDUCTS AT THE TOR FISCALE.

A. SECTION.

B. PLAN, SHEWING THE CROSSING OF FIVE AQUEDUCTS IN THE TOWER, AND TWO UNDER IT.]

At this important junction and crossing of the aqueducts the Marcian arcade originally made one of the usual angles. The more lofty arcade of the Claudia and Anio Novus was then carried over it, with the Anio Vetus half underground, nearly on the same line; and the modern aqueduct, called the Felice, is here carried against and partly upon the old Marcian arcade. The medieval architects took advantage of this crossing to build a tall tower upon it; the five conduits or _specus_ can be seen inside the tower, and half arches abutting against it in a very picturesque manner, all of which are shewn in the Section in the upper part of the plate, and in the Photo engravings.

The Plan in the lower part of the plate shews the arrangement, and also the small river Almo, now called the Marrana, winding round it.

PLATE X.

[Illustration: X.

THE AQUEDUCTS.—CLAUDIA AND ANIO NOVUS.

ENTERING ROME IN A TOWER OF THE SESSORIUM.

A. SECTION.

B. PLAN, OF THE PISCINA MADE IN THE TOWER.]

Piscina of the Anio Novus at the entrance into Rome, in a tower of the Wall of Aurelian, and of the gardens of the Sessorian Palace, now of S. Croce in Gerusalemme.

A. The Section.

B. The Plan.

By a singular coincidence it happens that the inner wall of this tower has been destroyed, so that the whole of the interior is displayed, and shews exactly what an ancient piscina was. The water comes into the right-hand upper chamber, it then descends into the chamber under it, as is marked by the arrow in the drawing, it then passes through small holes in the partition wall into the left-hand lower chamber. [The artist has represented a _large_ opening through this wall, but this must be a mistake, owing to the

wall being partially broken away; there are always _small_ holes through this partition wall.] The space between this tower and the corner of the wall in the Sessorian gardens, where it turns sharp to the west, was a large reservoir, or Castellum Aquæ, for the Claudia; it is not at a sufficiently high level for the Anio Novus.

PLATE XI.

THE AQUEDUCTS AT THE PORTA MAGGIORE AND THE PORTA TIBURTINA.

[Illustration: XI.

THE AQUEDUCTS.—AT THE PORTA TIBURTINA.

A. MARCIA, TEPULA, JULIA, AND FELICE.

THE AQUEDUCTS.—AT THE PORTA MAGGIORE.

B. MARCIA, TEPULA, JULIA, AND FELICE; CLAUDIA AND ANIO NOVUS CROSSING OVER THEM.]

In the lower part of this plate is seen the Wall of Rome on the northern side of the Porta Maggiore, with the tomb of Eurysaces the Baker in front of it. The wall here makes an angle, and the section of it is shewn just beyond the gate; the Claudia and Anio Novus (which here passed over it) are shewn in section, the _specus_ of the Claudia being nearly square, that of the Anio Novus over it considerably higher in its proportions. The Marcia, Tepula, and Julia here pass under these at a right angle, and through the wall, which in that part is made by filling up the arches of the Claudian arcade of the aqueducts. A pier of the Marcian arcade is shewn in the lower part of the section. The Aqua Felice is carried between the Julia and the Claudia, and it continues on to the Porta Tiburtina, always at the same level, over the Marcian arcade, but between the gates it passes through higher ground, and is therefore in that part underground, but emerges on arches at the two ends, near the gates, as Frontinus mentions. The Claudian arcade terminated at a tower in an angle of the wall, just to the north of this view, and with a great reservoir within the wall. In the upper view the Porta Tiburtina is shewn, with the Marcia, Tepula, and Julia passing over it. The different levels of the old road and the new one are also shewn. The arch on which the aqueducts are carried has inscriptions upon it of the time of Augustus, A.D. 10, and is of his time; it is buried up to the springing of the actual arch; the jambs are entirely buried by the filling up of the foss-way, but the two arches of the time of Honorius, A.D. 405, are tall arches, standing on the ground at its present level; the raising of the level of the road, therefore, took place between A.D. 10 and A.D. 400.

PLATE XII.

ANIO NOVUS—NYMPHÆUM, WHERE THE TROPHIES OF MARIUS WERE HUNG.

A. SECTION OF THE TOWER AND ARCHES.

B, C. PLANS OF THE THREE STORIES.

[Illustration: XII.

THE AQUEDUCTS.—ANIO NOVUS.

AT THE NYMPHÆUM, WHERE THE TROPHIES OF MARIUS WERE HUNG.

A. SECTION OF THE TOWER AND ARCHES.

B. C. PLANS OF THE THREE STORIES.]

This Nymphæum is represented on one of the coins of Alexander Severus, and belonged to the great Thermæ of the third century on the eastern side of Rome, which, having been long in progress, are called by the names of different emperors of that period. The ground had been originally the Exquiliæ, the great burial-ground of the time of the Republic, afterwards the garden of Mæcenas; it is full of aqueducts of different periods, and at different levels, and there are several reservoirs for them, some underground, others at a higher level. This one was formerly considered to have belonged to the Aqua Julia, but on taking the levels it appears that the only water in Rome that is high enough to reach it is the Anio Novus, the highest of the aqueducts, and the water has been brought from a reservoir belonging to that, near the Porta Tiburtina; having just been brought along the high bank on which the Wall of Rome stands, part of an arcade of an aqueduct leading to it remains, coming from that gate. Near the Porta Maggiore there are

also remains of an aqueduct at a very high level, coming from the Anio Novus, but the construction of the arcade is of the third century. It is now part of the wall.

This Nymphæum or reservoir at that high level has several branches leading from it, one of which goes in the direction of the other great reservoir on the Esquiline Hill, called the _Sette Sale_, and this, from the high level, probably supplied the Sette Sale and the Thermæ of Titus and Trajan.

PLATE XIII.

RIVER ALMO. DIVISION INTO TWO BRANCHES, NOW A LOCH OF THE MARRANA.

[Illustration: XIII.

RIVER ALMO, NOW THE MARRANA.

DIVISION INTO TWO BRANCHES, NOW AT A LOCH OF THE MARRANA. PLAN, VIEW, AND SECTION.]

This loch is situated about half-way between the Tor Fiscale and the farm-house called Roma Vecchia, rather more than three miles from Rome, and a quarter of a mile to the left of the Via Appia Nova. The Almo is a mountain stream coming down from the Alban hills, often flooded in the rainy season and dry in the hot season, with a very deep bed called a foss. This bed was convenient for the engineers who made the mill-stream, now called the Marrana, in the twelfth century, and they used it when the ground was high and the foss deep; but in other parts, when the ground was low and liable to be flooded, they banked up the stream, or made a new channel for it on a raised bank, for sometimes half a mile together, then joined the old winding bed again for perhaps another mile. At the point where the division into two streams takes place, one branch is banked up and comes through Rome, the other remains in the deep bed and receives the surplus water from the loch, made at this point, and this second stream runs through the valley of the Caffarella, and has its mouth near the church of S. Paul f. m. The Plate shews the plan at the division, one section of the loch, and the lasher. The second stream has no other beginning than this division, and the deep bed or foss can be traced in its winding course by the side of the cross-road from the Via Appia Nova to S. Urban, at the head of the valley of the Caffarella.

PLATE XIV.

RIVER ALMO, NOW THE MARRANA.

ENTRANCE INTO ROME UNDER THE PORTA METRONIA.

[Illustration: XIV.

RIVER ALMO, NOW THE MARRANA.

ENTRANCE INTO ROME UNDER THE PORTA METRONIA.

A. ELEVATION, WITH THE BRIDGE UNDER THE GATE.

B. PLAN AND SECTIONS—A. B. THE BRIDGE; C. D. SECTIONS.

C. PLAN OF THE GROUND WITHOUT AND WITHIN THE WALL OF ROME.]

A. Elevation, with the bridge under the gate.

The lower bridge under the modern road is of the time of the Early Empire, and can be seen, though not without some little difficulty, by climbing upon the bank of the mill-stream, which now runs in the deep winding foss of the Almo, and makes a bend under the gate, as is seen in the small plan in the centre, marked M.

B. Plan and sections, longitudinal and transverse, of the bridge, with the gate upon it. The longitudinal section A B has the line of it, marked on the small plan M; the transverse section is marked C D.

C. Map of the corner of the Wall of Rome, shewing the great bend that it makes to the south at this point. The wall is indicated by the towers at short intervals, and the stream of water by its winding course. The roads within the walls, and the road on the outside under the wall are also indicated. The house shewn in the lower part, to the left in the plan, is believed to be on the site of that of

Crassipes, the father-in-law of Cicero, near the Via Appia. The stream after passing the road turns sharply round to the north, under the cliffs of the Aventine, and runs through the Vallis Murcia, in which the Circus Maximus was made, first having passed by the Piscina Publica, under that part of the Aventine on which the Reformatory of S. Balbina now stands.

PLATE XV.

RIVER ALMO. MOUTH IN THE PULCHRUM LITTUS. VIEW.

[Illustration: XV.

RIVER ALMO, NOW THE MARRANA.

MOUTH IN THE PULCHRUM LITTUS. VIEW.]

This is the mouth within the Walls of Rome from the earliest period, and it was here in all probability that the priests washed the blood off their knives, and not at S. Paul's, a mile outside the town. The remains of the early wall of tufa in this part are well shewn in the drawing, and the mouth for the stream to pass through, left when the wall was built. This was part of the second Wall of Rome, built when the peace was made between the Romans and the Sabines. The construction of that period, of the usual large blocks of tufa with very fine joints, is clearly shewn in the drawing.

PLATE XVI.

RIVER ALMO. MOUTH IN THE PULCHRUM LITTUS. PLAN.

[Illustration: XVI.

RIVER ALMO, NOW THE MARRANA.

PLAN OF THE MOUTH IN THE PULCHRUM LITTUS.]

In the Plan the old arrangement is clearly shewn, and the division of the stream into two branches, one of which now turns a mill-wheel, and is probably part of the alterations in the twelfth century,—this is the straight line. The other is probably the original end of the stream, or at least of this branch of it. The frequent change of the sand-banks by the great floods of the Tiber sometimes obscure this part. Advantage was taken of the water being low in the Tiber to get this plan and the view in Plate XV.

THE AQUEDUCTS.

PLATE XVII.

SOURCES OF THE AQUA APPIA.

[Illustration: XVII.

SOURCES OF THE AQUA APPIA.]

DESCRIPTION OF PLATE XVII.

SOURCES OF THE AQUA APPIA[233].

A. Spring in a very ancient stone-quarry on the bank of the river Anio, probably one of those from which Servius Tullius had obtained the stones for his great wall, which had been floated down the river on rafts. The spring is so filled up with broken stones that it looks like merely a pond formed by drippings from the roof and the earth above, but the shepherds are certain that it is a spring, and the water never fails.

B. Central reservoir where two streams meet and are united in one _specus_, which conveyed the water into Rome. The aperture in the rock above is not original, or it has been greatly enlarged. This was probably a well to draw water for the cattle, and to give air to the _specus_.

C. Two streams coming out of a sort of double cave, and meeting at the mouth of it, from whence they are carried across the meadow in a _specus_ open at the top for a certain distance, and having the appearance of a ditch only; but the water from this

spring also never fails, and these two streams united gave a certain steady supply to the aqueduct. The meadow through which these streams flow has a clay soil, and the water is always liable to be muddy after rain, and left a large deposit of clay in the _specus_, as is shewn in other plates.

THE AQUEDUCTS.

PLATE XVIII.

AQUA APPIA, OR APPIAN AQUEDUCT.

[Illustration: XVIII.

THE APPIAN AQUEDUCT PASSING OVER THE PORTA CAPENA AND THROUGH THE TOWER.]

DESCRIPTION OF PLATE XVIII.

AQUA APPIA, OR APPIAN AQUEDUCT.

Crossing the valley from the Cœlian to the Aventine upon the _agger_ of Servius Tullius and over the Porta Capena, this was the only part that was above ground, as we are told by Frontinus[234]. In this view the pavement of the Via Appia is seen in the foreground, then the wall of Servius Tullius, twelve feet thick, (as usual with the walls of the Kings;) by the side of this, to the left, is seen the arcade that carried the _specus_ of the aqueduct; this goes as far as the branch of the river Almo (now called the Marrana), which runs through the valley. On the further side of the stream the land is high, and the aqueduct is again underground, but it has been traced not only across the valley, but under the cliff on the northern side of the Pseudo-Aventine, with a branch to the left to supply the Piscina Publica, which was an enormous swimming-bath for the whole population of Rome at that period, extending as far as the north end of the Thermæ of Caracalla, where the hollow with the bank round it can still be seen, and where a great reservoir remains, lined with the cement called _opus signinum_ (or _coccio pisto_). The ruins of another great reservoir rebuilt in the time of Trajan are at the north-west corner, nearly under the Aventine, and are called the Piscina Publica.

THE AQUEDUCTS.

PLATE XIX.

PLAN AND SECTION IN A CAVE IN THE AVENTINE.

[Illustration: XIX.

AQUEDUCTS—PLAN AND SECTIONS IN A CAVE IN THE AVENTINE]

DESCRIPTION OF PLATE XIX.

PLAN AND SECTION IN A CAVE IN THE AVENTINE.

This is the same cave on the Pseudo-Aventine, nearly under the church and monastery of Santa Sabba, which has been before described when partially excavated (Plate III.[235]), but which has now, in 1875-6, been more thoroughly examined and made accessible.

A A. General Plan of this part of the _specus_ of the Aqua Appia, made into a stone-quarry for many years, and part of it still in use for that purpose, but another large part has been long out of use[236].

B. Entrances to the two parts, the steps distinguish that leading to the part excavated.

C C. Section of part of the cave-quarry.

D. View of that part of the _specus_ of the Aqua Appia which is built of squared stones, and has a terra-cotta water-pipe on each side of it.

E E. Longitudinal Section of this part.

F. Transverse Section of the same.

DETAILS OF THE PLAN A.

a a. Entrance to the cave or quarry.

b b. Via di San Paolo, the carriage-road to that gate.

c c. Via di Santa Sabba, the carriage-road up the hill to the south.

d. Via di Santa Prisca, the road up the hill to the north.

e e. The most perfect part of the _specus_ where it is built, and not merely a tunnel cut in the bed of tufa, as in other parts.

f f f f. Windings of the tunnels for the Aqueducts.

g g. Water-pipes of terra-cotta, by the side of the _specus_ in the part where it is built, and not merely cut out of the tufa.

h. The _specus_ half filled up with the deposit of clay.

i. Steps made to give access to the cave.

THE AQUEDUCTS.

PLATE XX.

THE JUNCTION AT THE WEST END OF THE CŒLIAN, NEAR THE CLAUDIUM.

PLAN AND SECTION.

[Illustration: XX.

AQUEDUCTS AT THE WEST END OF THE CELIAN]

DESCRIPTION OF PLATE XX.

THE JUNCTION AT THE WEST END OF THE CŒLIAN, NEAR THE CLAUDIUM.

PLAN AND SECTION.

A B C. Line of the Section.

a. Colosseum.

b. Claudium.

c. Arch of Dolabella.

d. Reservoir and Spring of water.

e. Aqueduct of Nero.

f. Cave-reservoir and Spring, with ten wells down into it, erroneously called a _vivarium_.

g g g. Porticus of the Claudium.

h. Church of SS. John and Paul.

i. —— S. John of Mata.

k. —— S. Maria in Domnica.

l. —— S. Gregory.

m. Clivus Scauri.

n. House of the family of S. Gregory the Great.

o. Villa Celi-Montana (formerly called Villa Mattei).

p. Vineyard of Marchese Rappini.

q. Ground called Orto Botanico.

r. Place of S. Gregory.

s. Arch of Constantine.

t. Meta Sudans.

u. Via Sacra.

v. Summa Sacra Via.

x. Proposed Drain, for turning off the water of this spring from the Colosseum.

y. Branch of an existing subterranean drain under the Via di S. Gregorio, between the Cœlian and the Palatine.

z. Excavation made in 1876 in the Vigna Rappini, in consequence of a land-slip; but nothing was found beyond an old quarry of tufa, at a great depth, and a branch of an aqueduct at nearly the same depth, the water having come originally from the spring in the cave (?) or quarry (?) called a _vivarium_.

THE AQUEDUCTS.

PLATE XXI.

SECTIONS OF THE SPECUS OF EACH OF THE FIFTEEN AQUEDUCTS OF ROME.

[Illustration: XXI.

SECTIONS OF THE SPECUS OF EACH OF THE 15 AQUEDUCTS OF ROME]

DESCRIPTION OF PLATE XXI.

SECTIONS OF THE SPECUS OF EACH OF THE FIFTEEN AQUEDUCTS OF ROME.

The names of each are given under the section of it, and it will be observed that no two are alike; this was no doubt done in order that the workmen might always know which aqueduct each belonged to, at the points where they cross each other, so that if there was any obstacle in one of them it might be readily removed. Some of those which came from a clay soil, as the Appia and the Virgo, were liable to get choked up by the quantity of deposit left by the water, and it was necessary to have them cleared out from time to time, as is still the case with the Virgo, now called the Aqua di Trevi. One of the small streams that were collected to form the Aqua Hadriana, which comes from near Gabii, was a petrifying spring, which quite choked up the _specus_ in the course of a century. It was restored by Alexander Severus, but the same water seems still to have been used. The Aqua Felice comes from the same sources, but the petrifying spring was carefully excluded, and now runs in a ditch, giving a coat of stone to the sticks and the weeds.

PLAN OF THE AQUEDUCTS. ON THE CŒLIAN.

[Illustration: AQUEDUCTS ON THE CŒLIAN AND ESQUILINE LEADING TO THE COLOSSEUM.]

PLAN OF THE AQUEDUCTS.

ON THE CŒLIAN[237].

Three branches diverge from the great central reservoir at the Arch of Dolabella,—one goes straight on, nearly due north to the Palatine, the second north-east to the Colosseum, and the third west to the Aventine.

AND ON THE ESQUILINE.

From the other great reservoir called the Sette Sale, or the Thermæ, and from thence to the Colosseum.

A.A.A. The drain under the road between the Cœlian and the Palatine, now called Via di S. Gregorio, leading to the Via Appia.

B. Arch of Constantine.

C. Meta Sudans.

D. Thermæ of Titus on the Esquiline, with the great _piscina_ called Sette Sale, and the aqueduct leading from it to the Colosseum.

E. Monastery and Church of S. Gregory.

F. Site of the Porta Capena, with the aqueduct over it, leading to the Piscina Publica under the Aventine: and on to the mouth at the Porta Trigemina, in the bank of the Tiber.

G. Church and monastery of SS. John and Paul.

H. Church and monastery of S. Clement.

I. The great reservoir and Piscina of Nero over the Arch of Dolabella, and reservoir of the Aqua Appia to the left of it; this is underground in the garden of the Villa Celimontana, and from thence the _specus_ goes underground to the cliff of the Cœlian, where another _piscina_ is shewn, near the bottom of the plan, to the left.

Under that part of the Cœlian Hill on which the Claudium stood are seen four _piscinæ_, two on the western side opposite to the Palatine, and two on the northern side opposite to the Colosseum; of these latter the one at the corner is of the time of Nero, that in the middle of the northern front is of the time of Alexander Severus, when the upper storey of the Colosseum was building of stone.

MAP OF THE AQUEDUCTS ON THE EASTERN SIDE OF ROME.

[Illustration: MAP OF THE AQUEDUCTS ON THE EASTERN SIDE OF ROME

Whiteman & Bass, _Photo-Litho' to the Queen_, 236, Holborn]

This map is reduced by photography from one made for this work on a very large scale, which was thought necessary in order to shew the line of the course of each aqueduct, which, being to a large extent subterranean, are not shewn in the usual maps of the country. In the immediate neighbourhood of Rome the lines are so complicated that they could only be shewn on this large scale. (At the Tor Fiscale, for instance, they remind English travellers of the railways at Clapham Junction near London. There are many coincidences between the aqueducts and the railways; both are carried at different levels in order to cross each other; both are in some parts in tunnels, and in other parts carried on embankments, or on arches). This map was made by Signor De Mauro, an engineer and surveyor, who took much interest in the work, and is generally very careful and accurate, under the direction chiefly of Dr. Fabio Gori, who is a native of Subiaco, near which the principal aqueducts have their sources. The author of this work went with them from time to time to verify what they had done, but as it was a work of several months, and necessarily done in the summer, it was not practicable for him to do more than to go to the source of each aqueduct and follow it down to its mouth. The large map, which covers one side of a room, being 135 ft. long and 90 ft. wide, has been reduced by photography to three different sizes; the first makes eighteen photographs of the usual size, called the "normal size," and the whole on this scale is about 15 ft. long and 10 ft. wide; this again has been reduced to two sheets[238], 21 ins. long and 14 ins. wide; and then to the same size as this outline; but on this small scale the lettering requires a powerful magnifying-glass, and therefore the bare outline has been taken from it to shew the general features of the line of the great aqueducts. The reservoir at the source of each is marked by a dark circle, and from each of them the line can be traced into Rome. Within the walls a separate and careful examination was required, as so much of the work is subterranean; this examination has been made, and the line of each of the aqueducts has been traced to its mouth. It will be observed that the _specus_ or conduit of each aqueduct is of a separate form, and this was no doubt necessary to distinguish one from the other, as they frequently intersect and cross one another in a very singular manner, and in case of repair being necessary, it would have been very difficult for the workmen to know which aqueduct was at fault, or how to find the part that wanted repair, without this arrangement.

1. The earliest aqueduct, the APPIA[239] (B.C. 312), being entirely underground at a considerable depth, is marked by a dotted line. It comes from old stone quarries on the bank of the river Anio, just beyond the Caves of Cervaro, about eight miles from Rome, near the ancient Via Collatina, called by Frontinus Prænestina, because in his time the road to Præneste went through Collatia.

2. ANIO VETUS[240] (B.C. 272), comes also from the bank of the river Anio, but at a much higher level than the Appia, between Tivoli and Subiaco, near the village of Agosta, twenty miles from Rome, but the winding course makes the whole length of the aqueduct 42 miles, 779 paces underground, and 221 paces (about 350 yards) above ground on a substructure. It is brought at a considerably higher level than the Appia, but still underground for the most part, though near the surface, and sometimes only half underground. It was not legal to build over an aqueduct anything but another aqueduct, consequently the later aqueducts are all brought on the same line, each on a higher level, so that the line of the Anio Novus, carried on the arches of Nero, shews at the same time the line of the Anio Vetus nearly under it.

3. MARCIA[241] (B.C. 145). This stream also comes from near Subiaco, 39 miles from Rome, 36 on the Via Valeria, and 3 off it on a cross-road, near the village of Arsoli. There is a small lake 38 miles from Rome on the same road (which is another source of this aqueduct), into which the water gushes out from under the limestone rock; it is intensely cold in all weathers, and the water is of a light green colour in the lake. “The length of the course is 61 miles 710 paces, of which 54 miles 247 paces are underground, 7 miles 463 paces above ground, on an arcade for 6 miles 472 paces, on a substructure for 528 paces,” and in several places on bridges across the gorges in the hills. This water was brought into Rome again in 1860-70 by a new line, and was then called Aqua Marcia Pia, from Pius IX.; the name of Pia has since been dropped.

4. VIRGO[242] (B.C. 21), made by Agrippa for his Thermæ, restored to use by the popes in the eighth century, and frequently repaired; now called the Aqua di Trevi, from the fountain so named. The source is on the Via Collatina, 8 miles from Rome and 1 mile beyond the source of the Appia. There are several springs, each with a separate small reservoir, collected in one large reservoir, now under the road. “The length of the course is 14 miles 105 paces.”

5. TEPULA[243] (B.C. 126). The sources of this are 12 miles from Rome, near Grotta Ferrata and Marino, 2 miles from the old Via Latina.

6. JULIA[244] (B.C. 34). This source is on the cross-road from Grotta Ferrata to Marino, on the old Via Latina, 14 miles from Rome, and also 2 from the Via Latina (there are still washing-places at each of these two sources). The two streams, when they arrived on the level ground at the foot of the hill, were carried on the same arcade as the Marcia for 6 miles into Rome.

7. AUGUSTA[245]. This name is a mistake of the artist for Aurelia; it is the aqueduct made by Marcus Aurelius for the Villa de Quintilii on the old Via Appia, and united with the Severiana to supply the Thermæ Aurelianæ et Severianæ in Rome.

8. ANIO NOVUS[246] (A.D. 52). “The source of this is 42 miles from Rome, on the Via Sublacensis; the length of the channel is 58 miles 700 paces, of which 49 miles 300 paces are underground, 9 miles 400 paces above ground, 2 miles 3 paces in the upper part and near the City, 609 paces on substructure, 6 miles 491 paces on an arcade of the highest arches, in some places 109 ft. high.” This stream was part of the river Anio itself; a great dam was made across the river in a rocky part, about 2 miles above Subiaco. A great loch (_lacus_) was formed between this dam and a natural cascade about a hundred yards higher up the river, and a _specus_ was cut in the rock by the side of it at rather a lower level than the top of the dam, so that the water of the river must go into the _specus_ and so into Rome, before any of it could fall over the artificial cascade made by the dam. From this cause the water of this aqueduct never failed in the hottest and driest weather, but it was sometimes muddy after a flood in the upper country, and had many _piscinæ_ or filtering-places for that reason; there is usually one at each half mile in the arcades near Rome, and a _castellum aquæ_, or reservoir along with it, at each of the angles, made to break the force of the water.

9. CLAUDIA[247] (A.D. 38). The source of this is 38 miles on the Via Sublacensis, just above Subiaco, about 2 miles nearer to Rome than the Anio Novus. They are carried in two distinct _specus_ as far as Tivoli and to the foot of the hill, but on the level ground; both _specus_ are carried on a lofty arcade, which turns at an angle at every half-mile, and there has a _piscina_, and at each of these points it was carried across the lower arcade, which served for the Marcia, Tepula, and Julia.

10. HADRIANA or TRAJANA[248] (A.D. 120), and ALEXANDRINA (?). The sources of this are under La Colonna, about three miles from Gabii. The _specus_ is carried on a fine arcade for two or three miles between the two great roads. The same water was afterwards used for the Felice, with the exception of one of the springs, which was found to be of a petrifying quality, and had choked up the _specus_ of the old aqueduct. It seems probable that the stalactite produced by the petrifying spring had choked up the _specus_ of Trajan and Hadrian before the time of Alexander Severus, that he restored it to use, and it was then called by his name. The construction of the Piscina and Castella Aquæ near the source is distinctly of the time of Hadrian, but in some parts the arcade which carries the _specus_ is of the time of Alexander Severus.

11. SEVERIANA[249] (A.D. 190). The sources of this are in a swampy ground on the lower part of one of the Alban Hills, under Marino and Grotta Ferrata, nearly the same as those of the small river Almo, and the Tepula and Julia. The course is at first underground as far as the Torre di Mezza Via di Albano; from thence it is carried on a fine arcade of the third century to the Villa de Quintilii, and from thence into Rome for the Thermæ of Aurelius Commodus and Septimius Severus, near the Porta Latina.

12. ALEXANDRINA (?)[250]. There is some doubt about the source and the line of this aqueduct.

13. ALGENTIANA[251]. This aqueduct went to the Thermæ of Diocletian, where the _specus_ has been found, but it is almost the same as the last. Both were probably branches from the great early aqueducts.

14. AQUA FELICE[252], A.D. 1587. Made by the Pope, Felice Peretti, or Sixtus V. Its source is the same as that of the Hadriana, which was mistaken in his time for the celebrated Aqua Marcia.

15. AQUA MARCIA PIA. The real old Marcian water was brought into Rome by a Company in 1860-70. The course as far as Tivoli is in a stone _specus_, like the old aqueduct, but after it reaches the level ground it is carried in cast-iron pipes on the other side of the river Anio, and passes under it by a great syphon. This was to avoid repeating the great circuit made by the old aqueduct, and was also done to escape the necessity of crossing the mouths of the number of small streams that fall into the river Anio and drain the Campagna; these are often flooded in the wet season, and would have been likely to injure the bridges of the aqueducts where they crossed the stream; the iron pipes avoid them by being on the other side of the river.

MAP OF THE AQUEDUCTS ON THE WESTERN SIDE OF ROME[253].

[Illustration: MAP OF THE AQUEDUCTS ON THE WESTERN SIDE OF ROME

Whiteman & Bass, _Photo-Litho' to the Queen_, 236, Holborn]

The account given of the map of the eastern side of Rome applies almost equally to this, but the difficulty to be surmounted was here greater. Neither Dr. Gori, nor Signor De Mauro, nor the author knew the ground; we had only Frontinus and Fabretti to help us, and the course is much more subterranean on this side than on the other. There are none of the great arcades to carry the _specus_ for five or six miles; the only portion where they are carried on an arcade for any distance is on the side and upon the wall of the garden of the villa Pamphili-Doria, and there the arcade as seen is the work of Pope Paul V. (Borghese), who restored them to use in the sixteenth century, making use of the old subterranean _specus_ and the ruins of the old arches, which can be seen against the wall of that garden. From this point they are mostly subterranean, we traced them to the three lakes which served as reservoirs for them. The first _specus_ on this side of the Lacus Alsietinus has been kept separate from the one on the other side. In the time of Augustus the water came from the two upper lakes, but it was brought at a very low level, and the water from these being always muddy and bad, Frontinus, under Trajan, rejected it, and brought the water only from the Sabatina; Pope Paul returned to the use of the upper lake, Alsietina.

This map is also reduced by photography from one on a much larger scale, though not so large as the one for the eastern side, as that was found inconveniently large, and on this side there was less complication to examine and explain. Great credit is due to Signor de Mauro for the tact with which he traced the subterranean lines. He found that there are wells and air-holes at intervals, not always regular, but nearly so, and that when they are in grass-land or barren land, shrubs have always grown over the top of each well on account of the moisture that remained in it, and by means of these shrubs he was able to follow the line.

These aqueducts, which supplied the fountains in the Trastevere, all come from the lakes on the hills. The Alsietina of Augustus comes from the lake of that name (now called Martignano), between the Via Claudia and the Via Aurelia, but not very near to either, being 6½ miles from the Via Claudia at the fourteenth milestone, as Frontinus states. This was made to supply the Naumachia of Augustus, which were near the present monastery of S. Cosimato in Trastevere; the water was very abundant, but not fit for drinking. It entered Rome at a lower level than any of the other aqueducts, because the Naumachia were very little above the level of the Tiber. At the small town called the Cariæ (near the present Osteria Nuova), about fifteen miles from Rome, it received an additional supply of water from the Lacus Sabatinus. Trajan restored to use that part which came from the latter lake; this is better water than the Alsietina. Pope Paul III., A.D. 1540, again restored this to use, and it is now called Aqua Paola. His engineers brought the water from three lakes, the two before mentioned, and a smaller one above the Alsietina, called Stracciacappe. The object of bringing the water from this very high level, 500 ft. above Rome, was to supply the splendid fountains in front of S. Peter's, the water of which rises to a great height. This lake was drained in 1870, and at the same time the water in the Alsietina was also much lowered, by which means the three _specus_ were brought to light on the bank, and the sites are shewn on this map. The

Aqueduct of Trajan was carried at a much higher level than that of Augustus, and entered Rome on the top of the Janiculum. Procopius, in the sixth century, admired the profuse supply of water at that point; and the water was then, as it is now, used for a series of mills on the slope of the hill. The engineers of Pope Paul made use of the water of all the three lakes, and a most abundant supply still flows into Rome through the Fountain, above the Church of S. Pietro in Montorio. How far the old _specus_ was used it is difficult to tell, but most probably that of Trajan was used for a large part of the distance; it is almost entirely underground until the last mile into Rome, where it was carried on an arcade of the time of Trajan. The Aqua Paola is there also carried on an arcade, parallel to it and near to it, but not the same.

FOOTNOTES

[1] During the first season that I was resident in Rome, it was my habit to go with my friend Mr. William Long, of Balliol College, Oxford, then resident in Rome, into the Catacombs every Monday morning, and along the line of the Aqueducts also once or twice a-week, when the weather permitted. We procured all the best maps of the Campagna that were to be had, but could find none that would enable us to trace the course of the Aqueducts. Moltke's map is the best as far as it goes; but, being intended as a military map only, he paid no attention to the antiquities. The one known in England by the name of Gell, and in Rome by the name of Nibby, is made especially for the Antiquities; but it is on a small scale, and we found it impossible to trace the Aqueducts upon it. Eventually I have had one made on a large scale, to make it clear, have added the other Antiquities, and then had it reduced by photography to two smaller sizes: one very small, to give the general lines only; the other on a size convenient for the pocket; and, by using the portion near Rome separately, it makes a good and convenient map for the purpose.

[2] Frontinus is usually said to have died A.D. 106.

[3] See notably Plutarch, Vita Anci Marcii; Dionys., Hal. Ant. Rom., lib. iii. c. 679, sect. 9; Strabo, lib. v.; Cassiodorus, lib. vii. cap. 6, &c.

[4] These wells may have included the cisterns for holding rain-water, one of which exists on the Palatine.

[5] In the best text, that of the MS. at Monte Cassino, and in the best printed edition of the text, that of Buecheler (Lipsiæ, 1858), the passage runs "Salubritatem enim ægris corporibus afferre creduntur, sicut _Camænarum, et Apollinis, et Juturnæ_." The spring of the Camænæ or Muses referred to, is that which existed in the grove outside the Porta Capena, and beneath the western slope of the Cœlian. There was an Area Apollinis in the same Regio, and possibly there was a spring there; but no writer refers to it. A stream, now subterranean, still exists, and is very copious, running into and through the Cloaca Maxima; it may be seen in the excavations of the Forum Romanum. This subterranean stream comes from three different springs; the source of one is near the Arch of Titus, or more immediately in front of the usual entrance to the Palatine;—a second has its source near the foot of that part of the Quirinal Hill on which the Torre de' Conti and the Torre delle Milizie are situated; it now emerges in a cellar under a shop behind the church of S. Hadriana;—a third comes from the prison of S. Peter, at the foot of the Capitol. These streams meet near the church of S. Maria Liberatrice and the celebrated three columns of the temple of Castor and Pollux; by their union they formed the lake usually called after Curtius, but by Ovid the Lacus Juturnæ (Ovid. Fasti, l. i. ver. 708). This is not the same as the stream so called on Nolli's Map. The lake was between that part of the Velabrum of the Palatine on which the church of S. Maria Liberatrice and S. Teodoro are situated, which formed the southern side of the lake, and the Forum Romanum the northern side.

The Aqua Juturnæ, marked 1056 in Nolli's Map, is the stream that gushes out in great volume from the rock at the foot of the Palatine in the Lupercal of Augustus, which is now in a very ruinous state, the cave being used as a mill-head to a modern mill, between that point and the Cloaca Maxima. This cave is close to the Carceres of the Circus Maximus. The authority for the name of this stream is doubtful; it is now usually called Aqua Argentina, and falls into the Cloaca Maxima, near the church of S. Giorgio in Velabro and the arch erected by the silver-smiths in honour of Septimius Severus.

[6] The Augustan is a name applied also to a branch of the Marcian close to its source, as well as to one supplementary to the Appian within the city.

[7] Frontinus, c. 5.

[8] Ibid.

[9] "Jungitur ei ad Spem [Specum] veterem in confinio hortorum Torquatianorum et Pallantianorum ramus Augustæ, ab Augusto in supplementum ejus additus, ... loco nomen respondenti Gemellarum." (Ibid.)

[10] “Incipit distribui [Aqua] Appia imo Publicii clivo ad portam Trigeminam.” (Ibid.)

And again: “Rivus Appiæ, sub Cœlio monte et Aventino actus, emergit, ut diximus, infra clivum Publicii.” (Ibid., c. 22.) The cave reservoir which formed the mouth of this stream, where it was distributed, has been found near the Marmorata, or marble-wharf. The Porta Trigemina was between that and the Salaria, or salt-wharf. Both of the wharves are still in use. Some good antiquaries consider that the Porta Trigemina consisted of three double gates, at intervals along the narrow strip of ground between the Aventine and the Tiber, and that the one of which remains have been found near the Sublician bridge was the middle one of the three: if so, this cave would be literally _in_ the Porta Trigemina. In any case, it must have been close to it.

[11] That is, in the reservoir, or _castellum aquæ_, through which the conduit or _specus_ passed. This reservoir exists, or rather considerable remains of it, just within the Porta Maggiore, between that and the church of S. Croce, and just outside the _agger_ of the Sessorium, on which the road from S. Croce to this gate now runs.

[12] “... Cujus aquæ ad caput inveniri mensura non potuit, quoniam ex duobus rivis constat. Ad Gemellos tamen, qui locus est infra Spem (_Specum_) veterem, ubi jungitur cum ramo Augustæ, inveni altitudinem aquæ pedum quinque, latitudinem pedis unius, dodrantis: fiunt areæ pedes octo, dodrans: ... quas esse ex eo adparet quod in plerisque urbis partibus perdita aqua observatur, id est quæ ex ea manat, sed et quasdam fistulas intra urbem illicitas deprehendimus, extra urbem autem propter pressuram libræ, quam vidi infra terram ad caput pedibus quinquaginta, nullam accipit injuriam.” (Frontinus, c. 65.)

[13] There is good reason to believe that such tombs were not _exclusively_ Etruscan, but were also used by the Latins and other nations at the same period, and this one may very well be early Roman.

[14] The modern carriage-road, so called, was called Via Gabina in the time of Frontinus. The old Via Prænestina is now a bridle-road only for the first three miles out of Rome, to the Torre de’ Scavi; it is then a cart-road, called Via Collatina, with a branch road into it from the present carriage-road.

[15] In the Map of Gell and Nibby, along the Via Prænestina will be seen the name _Pupinia_. The spot is just north of this, and not far off from the piece of road marked in the same map as the Via Collatina.

[16] Frontinus, c. 22.

[17] In the _Bullettino dell’ Instituto Archeologico_, and the _Civiltà Cattolica_, for the year 1861, it is stated that for the works of the iron railroad between the Via Labicana and the Via Gabina the _specus_ of the Aqua Appia was found, 450 yards (metres) from the Porta Maggiore. It was constructed of square stone of tufa, and was incrusted with _tartar_, had an acute vault, which was 5 ft. 9 in. high, and 2½ ft. wide.

[18] This is on the line of the wall of Servius Tullius. It appears that Trajan made a reservoir here over the old one. The _specus_ of the Appia passes through the present gardener’s house lengthwise, from east to west. This _specus_ was found again in another excavation to the west of it, by the side of the present road.

[19] “Substitit ad veteres arcus _madidamque_ Capenam.” (Juvenal, sat. iii. ver. 11.) “Capena grandi porta qua _pluit gutta_.” (Martial, lib. iii. epigr. 47.) The distance from the foot of the Cœlian to the Marrana is just a hundred yards along the line of the wall of Servius Tullius, across this part of the valley or great primitive foss. The ground on the side of the wall is all made earth and rubbish, and two aqueducts are carried on arcades against the wall, one on either side. These arcades have not been traced beyond the Marrana, the ground there being higher. At the Piscina Publica, where another pit was dug 20 ft. deep, the wall is built against the tufa rock, and there is a third _specus_ in a tunnel in the rock under the wall.

[20] Or perhaps the road was a deep foss-way, and the _specus_ passed over the arch of the gate at this point, where four roads meet.

[21] In the spring of the year 1870, another excavation was made close to this point, and a way was found into another old subterranean stone-quarry long out of use. Through this cave, or quarry, the _specus_ of five different aqueducts pass on their way to the Tiber. Some of these come down at a steep decline, and the water of the whole seems to have been carried into the lowest one, the Appia, at this point. This _specus_ must have been carried over the deep foss-way upon or under the arch of the gate of the old wall of _the city_, where four roads meet. It is also visible again in another old subterranean stone-quarry on the other side of the road, nearly under S. Prisca, and from thence it must have gone to the old cave, used as a reservoir near the Marmorata, and the Porta Trigemina, immediately under the monastery of S. Maria del Trinita di Malta, where the _specus_ is again visible, and

where the wells of other aqueducts run into the same cave reservoir at the mouth of the aqueducts in this part of Rome. One of these runs down a vertical pipe from the reservoir nearly over this cave, but under S. Sabina on the hill above, excavated in 1865, and described by M. Descemet (Sect. xi.) There is another large reservoir in the interior of the hill, still full of water, supplied by a spring rising there; the water from this still passes through the same passage to the Tiber. This is also said to have been called the cave of Faunus by the poets. It is probably also the same as that of Cacus, being a large natural cave, with a spring of water, and a natural reservoir of considerable size in it about knee-deep, the entrance to which is by a narrow passage made into the _specus_ of the aqueduct. Such a cave might very well have been used to drive cattle into for concealment, and a resolute, well-armed man standing at the entrance might defend it against any number. Solinus (i. 7) says that the cave of Cacus was at the Porta Trigemina, and that he dwelt in the Salinæ, which are close by this spot. “Qui Cacus habitavit locum cui Salinæ nomen est, ubi Trigemina porta.”

[22] On the wall of the smaller reservoir, the fragment of an inscription, relating to the Thermæ of S. Helena, now in the Vatican Museum, is said to have been found:—

D. N. HELENA ... VEN. ... AVG. MAT. AVIA ... BEATIS ... THERMA ... SI ... ESTRV ...

[23] Frontinus says, c. 5, at the sixth milestone on the Via Prænestina, about nine hundred and eighty paces off to the left, and near the Via Collatina, this stream has its source. The sources both of the Aqua Appia and of the Augusta were traced by Signor Fabio Gori and Mr. J. H. Parker, in March, 1868, and were afterwards shewn to the British Archæological Society of Rome.

[24] The source of the _Appia_ was 780 paces off the road, between the 7th and 8th milestone. That of the _Augustan_ 880 paces off, and by the 6th milestone. The former was measured to its termination, giving 11■ miles. The latter went only to the “Specus Vetus” (which is two miles less) and gave 6■ miles. Two miles is the distance from the Porta Maggiore to the Porta Trigemina and the Salaria. In all probability the Augustan branch was carried for the six miles into Rome along the bank of the Via Prænestina, here a deep foss-way between two high banks; and at a later period the Aqua Virgo was carried over it at a higher level, till within about half a mile of Rome, where it arrives at the outer bank of the great foss, and is carried at a sharp angle to the north to the Pincian. The Appia, being much deeper, was carried straight on at the bottom of the great foss into Rome, and entered at the extreme eastern corner, under the line afterwards taken by the Claudian arcade, to the two great reservoirs or _gemelli_ before mentioned; the main line running here parallel to it, a little to the south, till it reached the Piscina of S. Helena, the two lines converging at the _gemelli_.

[25] There are considerable remains of two large reservoirs in a garden just outside of the boundary-wall of the Sessorium, which wall is of the time of S. Helena, on its western side. Some excavations made in them in 1869 under my direction shewed that they went to a great depth, the workmen being stopped by water. These two great reservoirs, so close together in the line of the Aqua Appia, seem to have been the Gemelli mentioned by Frontinus. From this point the _specus_ can be traced along the Cœlian, and the reservoirs are below the level of that _specus_ (_infra specum veterem_).—F. ii. 65.

[26] If the “Plautian” be the better reading, they may have been the gardens of Plautius Lateranus, which were near those of the Sessorian Palace.

[27] Frontinus, cap. 19: “Marcia autem partem sui post hortos Pallantianos in rivum qui vocatur Herculaneus, dejicit.” Cap. 20: “Finiuntur arcus earum (Anionis Novi, et Claudiæ), post hortos Pallantianos.” Cap. 69: “Præterea (Julia) accepit prope urbem, post hortos Pallantianos.” In the _Notitia_ and the _Curiosum Urbis_ the “Horti Pallantiani” are given as being in the Regio V. or the “Esquiliæ.”

[28] Remains of these _thermæ_ were accidentally brought to light in 1871, during some excavations made by a building company, who had bought the ground on speculation. They are of great extent, and on both sides of the present road from S. Maria Maggiore to S. Croce in Gerusalemme, which was made in the sixteenth century by Sixtus V.

[29] “Exquiliæ locus in quo sepeliebantur corpora extra portam illam in qua est Sessorium.” (Acron ad Horat., lib. i. Sat. viii.)

“Eodem tempore fecit Constantinus Augustus basilicam in palatio Sessoriano, ubi etiam de ligno S. crucis D. N. Jesu Christi posuit.” (Anastasius in vita S. Silvestri papæ, xxxiv. § 41.)

[30] Frontinus, c. 6. Pyrrhus was king of Epirus, and came to the aid of the Samnites against the Romans; he was conquered _c._ B.C. 272.

[31] The passage is corrupt, as will be explained. The following is the reading, as given by Buecheler, whose text is _an exact copy_ of the best manuscript, that of Monte Cassino:—“Anio Vetus citra quartum milliarium _infra Novum_, _qui_ a via Latina in Lavicanam _inter_ arcus trajicit, et ibi piscinam habet. Inde intra secundum milliarium partem dat in specum, qui vocatur Octavianus, et pervenit in regionem _viæ Novæ_ ad hortos Asinianos, unde per illum tractum distribuitur. Rectus vero ductus, _secundum Spem_ (_Specum_) veniens intra portam Exquilinam, in altos rivos per urbem deducitur.” (Frontin., c. 21.) _Infra Novum_, therefore, signifies within the fourth mile on the Via Nova, the New Road of the time of Frontinus, the Via Appia Nova (?).

[32] Frontin., c. 18.

[33] Signor F. Gori, who is a native of Subiaco, and has followed the line of the aqueducts on foot from Subiaco to Rome, says that he has found the source of the Anio Vetus in the river Anio, at three miles from Subiaco, on the _Via Sublacensis vetus_, twenty miles from the old gate of Tibur or Tivoli, in the district called _Le Connotta_, where he finds two _specus_, the higher one the Anio Novus, the lower one the Anio Vetus. He traces the same _specus_ near Marano, a village thirty-eight miles from Rome, on the Via Sublacensis Neroniana, near _Vico-varo_; and again near Tivoli, on the bank of the _Valle degli Arci_. “Delle vere Sorgenti dell’ Acqua Marcia e delle altre acque allacciate dai Romani presso le Vie Valeria e Sublacense,” per F. Gori. Roma, 1866, 8vo., pp. 53, 54.

[34] The local _patois_ for _Albergo_ or _Auberge_.

IMP. CAESAR DIVI. F. AVGVST. EX . S.C. dclix. P. CCXL.

IMP. CAESAR . DIVI. F. AVGVST. EX . S.C. dclxix. P. CCXL.

[35] By the side of a plan of Rome in the first volume of his magnificent work (pl. xxxviii.), Piranesi gives a section of the relative heights of the Aqueducts, as compared with each other. The figures refer to the base of each _specus_ above that of the Appian, and the following is the result, according to his measurements, reduced to English feet:—

Above Specus of Appian. Palmi. Feet.

Anio Novus 173.8 127 Claudian 163.2 119 Julian 145.1 106 Tepulan 138.7 101½ Marcian 128.7 92½ Anio Vetus 75.4½ 55½ Virgo 9.3 7 Appian — —

At a lower level than Specus of the Appian.

Alsietina in the Trastevere 37.6½ 27½

He gives as the total full range, i.e. from the _specus_ of the Alsietina (the lowest), to that of the Anio Novus (the highest), as 211.2½ _palmi_, or 154½ English feet. The height of the Appian, he shews by his diagram to be about 24 English feet above the Quay of the Tiber. The points at which Piranesi obtained his measurements, and the mode employed, are not recorded. It seems hardly possible that the Appia is 55 ft. under the Anio Vetus in Rome.

[36] See ante. Frontinus, cap. 21.

[37] The passage, as it stands in the Codex Cassinensis, is, “Anio Vetus _citra_ quartum miliarium _infra_ novum _qui_ a Via Latina in Lavicanam _inter_ arcus trajicit, et ipse piscinam habet.” This piscina is visible at the third modern milestone on the Via d’Albano, and at the fourth on the Via Latina. The Codex Vaticanus is an inferior copy of the Codex Cassinensis; but the Codex Urbinas, now also in the Vatican Library, is distinct. No other MS. is of any authority.

[38] Remains of the tombs on the Via Latina are distinctly visible and rather prominent objects, close to the Torre Fiscale. The Marrana, or Almo, the small stream that received the surplus water of the aqueducts, also washes the foot of the tower.

[39] This _castellum aquæ_ is exactly two miles from the Porta Maggiore, another proof that the entrance _to Rome_ (though not to the City) was considered by Frontinus to have been at that gate. All the aqueducts on the eastern side of Rome are measured by him from this gate, and the inscriptions put over that gate as the entrance into Rome indicate the same thing. The level of this _castellum_ above the sea is about 153 ft.; at the Porta Maggiore, where the Anio Vetus enters Rome, it is about 146 ft., allowing a descent of about 3 ft. 4 in. for the two miles, which is natural. The Via Appia Nova, in the part near Rome, was made out of the old Via Asinaria. Frontinus says that this branch “was conveyed to the Asinian gardens,” which were between the Lateran and the Sessorium, and to which the Porta Asinaria (or gate of the Asinii) was the entrance. Between that gate and the Amphitheatrum

Castrense are remains of an ancient reservoir or _castellum aquæ_, cut in the rock at the foot of the wall and half underground, as was very usual with the Anio Vetus. The branch that goes along the Via Latina appears to have gone from the same reservoir, but to be distinct from the one mentioned by Frontinus, and to have been made after his time. This last branch seems to be the same as the Aqua Antoniniana of the Regionary Catalogue, having been made in the third century to supply the great Thermæ of the Antonines. In the Middle Ages, this was considered to have been a branch of the Aqua Marcia; but if this had been the case, there must have been some remains of the arcade for it across the valley.

[40] This branch is believed to have been called AQUA ANTONINIANA, as it conveyed water to supply the great Thermæ of the Antonines, called after Antoninus Caracalla. But it seems doubtful whether it may not be the SEVERIANA, which conveyed water to the Thermæ of Septimius Severus. There appear to have been two aqueducts along this point of the Via Latina at different levels, and the higher one, passing over the Arch of Drusus, is said to have been a branch from the Marcia.

[41] Frontinus, c. 21. On the subject of the word _Spes_ (?) or _Specus_ (?), see the Appendix to this Chapter.

_i_MP . CAESAR DIVI . F . AVGVST . EX . SC VI_i_ PCCXL C

[43] “Descrizione del luogo denominato anticamente Speranza Vecchia, del monumento delle Acque Claudia ed Aniene Nuova, e del Sepolcro di Marco Virgilio Eurisace, dell’ architetto cav. Luigi Canina.” 8vo., Roma, 1839, with six Plates; extracted from the Annali dell’ Instituto Archeologico.

[44] There are two other temples known to have been dedicated to Spes, and the one near the Porta Carmentalis is thus entered in the _Notitia_ and _Curiosum Urbis_: “Fortunæ et Spei Templa _Nova_.” We know that there had been a great fire here, and that these temples were rebuilt, and therefore the _Nova_ has reference only to the new structure. Besides, to be analogous, it should have been “Spes Nova,” or “Templum Spei Novæ.” According to Dionysius, another Temple of Spes was a mile or eight _stadia from the City_. (Dion. Hal., ix. 24.) “Having in the first battle, which was fought at the distance of eight stadia from _the City_, near the temple of Hope, overcome the enemy and beaten them out of the field, and after that fought them again near the gate called Collina,” &c. The Porta Maggiore, in the outer wall of _enceinte_, is just a mile from the Porta Esquilina, in the inner wall of _the City_, and the Arch of Gallienus. On the other hand, the line of the _specus_, with the foss-way by the side of it, must have been important ground for a battle. The modern theory that the whole of the eastern side of Rome was called after Spes, has no ancient authority. Another instance is on all accounts very puzzling. It is a passage in Lampridius, in the life of Heliogabalus: “Ipse secessit ad hortos Spei Veteris, quasi contra novum juvenem.” (Lampridius, Antoninus Heliogabalus, 13.) It would almost appear that there were some gardens called by the name of Spes, unless indeed in transcribing some such error should have been made as in the case of the transcriber of Frontinus, and “Spei” written for “Specus,” by a scribe to whom the former word was familiar but the latter not, who had mistaken _Spc■_ for _Sp■_. It is a strong passage in favour of the temple theory; but still there is strong evidence on the other side. This garden was that of the Sessorium, one side of which was enclosed by the arcade carrying the _specus_ of the Claudian aqueduct.

[45] The seven places where the abbreviation of _spem_ or _specum_ occurs in Frontinus are given in another page, with tracings of these passages from the best manuscript.

[46] Polenus and Buecheler have demonstrated that the Codex Cassinensis is the earliest and best. It was discovered at Monte Cassino by Poggio in the fourteenth century. The Codex Vaticanus is a copy of the above; but the Codex Urbinas, though of later date, is not a copy from that manuscript. Probably both are copies from an earlier one, not now extant. Some of the various readings in the Codex Urbinas are better than those of the Codex Cassinensis. See the edition of Frontinus by Polenus, Prolegomena, p. 20. Patavii, 1722, 4to.

[47] Other excavations, made in 1871 in the large vineyard near the Porta Maggiore, near the building called Minerva Medica, shewed the aqueducts very distinctly passing through the higher ground and going along the line of the wall towards the Porta di S. Lorenzo.

[48] Frontinus, c. 87.

[49] Piranesi, Le Antichità Romane, vol. i. pl. x.

[50] I am indebted to the kindness of the abbot of the monastery at Monte Cassino, for the tracings of these passages here reproduced by the process of photo-engraving.

[51] The manuscript called _Codex Urbinas_ reads, _jungitur ei ad anionem veterem_. In the present instance, the true reading is evidently _specum_. Frontinus is describing the Aqua Appia, the oldest of the aqueducts, and the junction of the Augusta with the old _specus_. This could have nothing to do with the Anio Vetus.

[52] _ascus_ (?): Buecheler reads this _ad spem_.

[53] The Torquatian Gardens were near the Porta Maggiore, and probably the same as those of the Sessorium, now those of Santa Croce in Gerusalemme.

[54] Canina published a volume on what he considered to be the Temple of Spes, by the side of the Porta Maggiore (as before mentioned); but a few years afterwards those ruins were pulled down to make room for a modern guard-house. In doing so, the inscription of the dedication to HERCULES was found by the architect, Felice Cicconetti, and sent to the Vatican Museum. This statement was made to me some years since by Signor Cicconetti himself, and was confirmed by his friend, Signor Simelli, the photographer, who said he had seen it.

The fact is now denied by the Roman archæologists, and when challenged by the Cavaliere Visconti to shew him the inscription in the Vatican Museum, they say they cannot now remember anything about it; and the stone with the inscription upon it has not been found. It is printed by Dr. Henzen in his collection of Inscriptions as _then_ in the warehouse of the Vatican Museum; but he considers it to have belonged to a wayside altar only, not to a temple.

The twin reservoirs are very near the same spot; but the place where the Aqua Appia enters Rome is in the gardens of the Sessorium, some distance from the gate, to the east of it. An old _specus_ certainly runs along the Cœlian Hill, nearly under the Neronian Arcade, and part of it is now used for the Aqua Felice. I have been along it for more than a quarter of a mile, from near the Porta Maggiore to the Lateran. The Aqua Felice is carried down a sharp incline into that old _specus_, and the metal pipes on the slope are still supported on brickwork of the first century, probably part of the Marcian Arcade, when rebuilt in that part by Frontinus. The old _specus_ runs on (or ran on, it is said to be now interrupted,) to the reservoir on the Cœlian Hill, at the Arch of Dolabella.

That a part of the eastern side of Rome went by the name of _Spes Vetus_, is said to be proved by a curious graffito upon the bottom of an amphora, found in 1871 in the excavations in the Exquiliæ, near the Porta Maggiore, of a cobbler's stall, in that district:—

TYCHICI SVTORIS A. SPEM VE TERE.

This piece of _terra-cotta_ is of the first century of the Roman Empire; but _at what period_ the name and address of the cobbler was scratched upon it, is a question not so easily answered.

[55] The Aqua Claudia and Anio Novus enter Rome at the extreme eastern point on a lofty arcade, which formed the northern boundary of the Sessorian gardens, and was incorporated in the Wall of Aurelian. This extends for about a quarter of a mile; it then turns at a sharp angle to the north, and passes over the Porta Maggiore, to its final reservoir in a tower at an angle to the north of that gate. But part of the water of the Claudia and the Anio Novus united, was carried straight on along the bank on which the arches of Nero stand, to the Cœlian Hill and the reservoirs at the west end of it. The temple, called by Canina _Spes_, stood near the angle where the water was divided into two distinct channels, between that point and the Porta Maggiore.

[56] The name of _Porta Esquilina_ is here given to the Porta Maggiore, the outer gate on the road to the Esquiline. The same name was also given to the inner gate in the _agger_ of Servius Tullius; but there must always have been an outer gate also in the outer _mœnia_, or bank and wall for enclosure, which was a necessary part of every fortified city. (The same name, _Porta Angelica_, is still given to both the inner and the outer gate of the Leonine City, near the Vatican.) The high streams were carried on this bank to the Porta Viminalis of Frontinus, now called the _Porta di S. Lorenzo_. The remains of these three aqueducts can be plainly seen on entering through the city wall close to the Porta Maggiore, on the north side, and going along on this bank to the Porta di S. Lorenzo. The _specus_ is visible at both ends, carried on arches. In the middle the ground is higher, and the _specus_ pass through it underground, and then emerge and are carried again upon arches, exactly as described by Frontinus. The Aqua Felice is carried _over_ the three aqueducts of the Marcian arcade; it is on arches twenty feet from the ground at each end, and in the middle, where these three are underground. The lower part of the _specus_ of the Aqua Felice almost touches the ground,

while the other three are underground.

[57] The _gemelli_ are, in all probability, the large twin reservoirs just outside the western wall of the Sessorium, now in a large vineyard near the Porta Maggiore, through which the Neronian arches pass. These reservoirs are below the level of the _specus_ of the Anio Vetus, as was shewn by some excavations made in them under my direction in 1869.

[58] Some of the water had been thrown into the old _specus_ at the junction of the Claudian with the Neronian arches.

[59] There are remains of more than one _specus_ crossing the valley from the Cœlian to the Aventine upon the _agger_ of Servius Tullius, and passing over the Porta Capena at the foot of the Cœlian. One of these was the Marcia, from the reservoir over the Arch of Dolabella, which is near the site of the Claudium and Temple of Claudius. There were great reservoirs for the aqueducts at this point on different levels; one of them underground is still in use, the remains of the others are among the most picturesque objects in Rome. This passage cannot apply to the temple of Hope, which is full a mile away from the Aventine.

[60] “Quum hæc accepta clades esset, jam C. Horatius et T. Menenius consules erant. Menenius adversus Tuscos, victoria elatos, confestim missus. Tum quoque male pugnatum est, et Janiculum hostes occupavere: obsessaque urbs foret, super bellum annona premente, (transierant enim Etrusci Tiberim) ni Horatius consul e Volscis esset revocatus: adeoque id bellum ipsis institit mœnibus, ut primo pugnatum ad Spei sit æquo Marte, iterum ad Portam Collinam. Ibi quanquam parvo momento superior Romana res fuit, meliorem tamen militem, recepto pristino animo, in futura prœlia id certamen fecit.” (Livii Hist., lib. ii. c. 51.)

[61] “Romæ fœdum incendium per duas noctes ac diem unum tenuit: solo æquata omnia inter Salinas ac Portam Carmentalem cum Æquimælio Jugarioque vico. In templo Fortunæ ac matris Matutæ et Spei extra portam late vagans ignis, sacra profanaque multa absumpsit.” (Ibid., lib. xxiv. c. 47.)

[62] “Comitia deinde a prætore urbano de senatus sententia plebisque scito sunt habita: quibus creati sunt quinqueviri muris turribusque reficiendis: et triumviri bini; uni sacris conquirendis donisque persignandis; alteri reficiendis ædibus Fortunæ et matris Matutæ intra Portam Carmentalem, sed et Spei extra portam, quæ priore anno incendio consumptæ fuerant.” (Livii Hist., lib. xxv. c. 7.)

[63] “Theatrum et proscenium ad Apollinis, ædem Jovis in Capitolio, columnasque circa poliendas albo locavit: et ab his columnis, quæ incommode opposita videbantur, signa amovit: clipeaque de columnis, et signa militaria affixa omnis generis dempsit. M. Fulvius plura et majoris locavit usus: portum et pilas pontis in Tiberim; quibus pilis fornices post aliquot annos P. Scipio Africanus et L. Mummius censores locaverunt imponendos; basilicam post argentarias novas et forum piscatorium, circumdatis tabernis, quas vendidit in privatum; et forum, et porticum extra Portam Trigeminam, et aliam post navalia, et ad fanum Herculis, et post Spei ad Tiberim ædem Apollinis Medici.” (Ibid., lib. xl. c. 51.)

[64] “Sive autem medii montes erunt inter mœnia et caput fontis, sic erit faciendum, uti specus fodiantur sub terra librenturque ad fastigium,” &c. (Vitruv., _De Architectura_, lib. viii. c. 6. § 3.)

[65] “Alexandria est fere tota suffossa, specusque habet ad Nilum pertinentes, quibus aqua in privatas domos inducitur.” (Aulus Hirtius, _De Bello Cæsaris Alexandrino_, cap. 4.)

[66] Frontinus, lib. i. c. 7. He also quotes from Fenestella concerning the delays which occurred, and speaks of the Decemvirs consulting the Sybilline books, and being supposed to have found that it was not the Marcian but rather the Anio which should be brought into the Capitol: (“Invenisse dicuntur, non esse aquam Marciam, sed potius Anionem in Capitolium perducendam.”) Eventually, however, Marcius prevailed, and his plan was carried out.

Pliny also refers to the work of Marcius: “Sed dicantur vera æstimatione invicta miracula; Q. Marcius Rex jussus a senatu aquarum Appiæ, Anienis, Tepulæ _ductus reficere_, novam a nomine suo appellatam cuniculis per montes actis intra prætura suæ tempus adduxit.” (Nat. Hist., lib. xxxvi. c. 121; see also further details in Plin., xxxi. 41, and ibid.)

[67] “Qui lapide quadrato ampliores ductus excitavit, perque illos aquam quam acquisiverit rei publicæ commodo, trium millium opera fabrorum duxit cui ab auctore,” &c. These words are wanting in the best manuscript, that of Monte Cassino. In place of them we have “(... priores ductus restituit et tertiam illam aquarum in urbem perduxit) cui ab auctore,” &c. This does not agree with the opinion of the learned, that the Urbinas Manuscript is a copy of the one at Monte Cassino, unless great liberties were taken with it. The fact that the arcade with the _specus_ of the aqueduct is always built of large squared stones, is strongly in favour of the Codex Urbinas. It is also certain from the nature of the work, that a large number of men must have been employed upon it. This

passage seems to have been omitted in the Codex Cassinensis, which is a proof that the Codex Urbinas is not a _copy_ from it. Dederich, p. 15, suggests after “commodo,” the words “trium millium opera fabrorum.”

[68] Frontinus, lib. i. c. 7.

Frontinus states in another chapter (c. 12) that Augustus brought underground another stream, which should be supplementary to the Marcian whenever the dryness of the season rendered extra supply necessary. It was called from the name of the contriver, Augusta, and had its rise above the spring of the Marcian. This additional _ductus_, or Specus Augusta, was 800 paces long.

[69] Frontinus, c. 18.

[70] “Salientibus aquis instruxit urbem.” Ibid., c. 9.

[71] Ibid., c. 87.

[72] Ibid., c. 8.

[73] Ibid.

[74] Ibid., c. 9.

[75] Ibid.

[76] Frontinus, c. 19.

[77] ‘The three aqueducts’ in this passage may mean either the Anio Vetus, the Marcia, and the Claudia, all of which come from the neighbourhood of Subiaco, and follow the same line on the bank of the river Anio, and the cliffs above it as far as Tivoli, but diverge considerably between Tivoli and the Piscinæ; or it may mean that the Tepula and the Julia coming from near Marino, and the Marcia coming from Tivoli, meet at this point—both are true. The _piscinæ_ of the Claudia, the Anio Novus, the Marcia, the Tepula, the Julia, are all within half-a-mile of each other.

[78] Dr. F. Gori says that the lake of S. Lucia, in the territory of Arsoli, near Subiaco, is _not_ the source of the Aqua Marcia, but of the Aqua Claudia only, and that the sources of the Aqua Marcia are nearer to Subiaco, and are called by the people _Acque Serene_. He also considers that the branch of the Aqua Augusta added to the Marcian by Augustus, now called _Le Rosoline_, comes from near the village of Agosta, and that the spring, now called _La Fonte_ (_Fons novus Antoninianus_), added to the Marcian by Antoninus Caracalla, is under the same village of Agosta. One of the inscriptions on the Porta S. Lorenzo records this. See Delle varie Sorgenti dell’ Acqua Marcia, &c., pp. 56, 57.

[79] The new company had at first proposed to draw their chief supply of water from the small lake called the Lago di S. Lucia, which is nearer to Rome, and which they had been misinformed was the Aqua Marcia. Dr. Fabio Gori, from his great local knowledge and his archæological researches, was able to shew that this was a mistake, and wrote to that effect a letter in the Roman newspaper called the _Osservatore Romano_. This letter at first gave great offence, and a very warm controversy was carried on for some time on that subject. Eventually, however, a new engineer of the company thought it better to examine the ground himself, and the result was to establish that Gori’s views were perfectly correct. He then became a warm advocate for the company, which he thinks entitled to great praise for the admirable manner in which its works in the valley of the Anio have been carried out as far as Tivoli. Their works almost equal those of the time of the Empire, and are carried out on the same principles; but from Tivoli to Rome the water is carried in metal pipes, and not in a stone _specus_ as it is above Tivoli. This enables the company to carry it in a more direct line.

[80] See the Appendix to this Section.

[81] A great deal too much importance has been attached to this Cyclopean Masonry, _Opus Cyclopæum_. See the Chapter on the Construction of Walls.

[82] It is probably the case that part of this supply was brought in metal pipes only, from the evidence of this inscription. A stone _specus_ passes under the wall on the bank round three sides of the camp on the exterior of the walls, and is plainly visible at the north-east corner; but this agrees with the general character of the Anio Vetus, and was probably a branch from that aqueduct.

The inscription is as follows:—

IMP. CAES. M. OPELLI . SEVERI . MACRINI . AVG M. OPELLI . SEVERI . DIADVMENIANI . CAES. PRINC. IV CASTRIS . PRAETORI TERENTIVS . CASSANDER . FECIT

[83] “[Honorius, Papa III.] Ecclesiam Sanctæ Bibianæ juxta formas aquæ Martiæ cum Monasterio Monialium restituit.” (Ciaconi, Vitæ Pontif. Roman., &c., vol. ii. col. 46, C.)

[84] An inscription recording repairs by Agrippa is said by Ligorio to have been found on a _cippus_ of travertine at the third mile on the Via Latina. The genuineness of this is doubted by Fabretti, because the number of miles does not agree; but it seems more probable that this was an error in transcribing, than that the inscription should be forged without any motive for doing so:—

AQVAE . IVLIAE . TEPVLAE. IMP. CAES. DIVI . IVLI . F. AVGVSTVS . PONTIF. MAX. COS. X■I■I■. TRIB. POT. X■I■X■. IMP. X■I■I■I■. CVRANTE M. VIPSAN . AGRIPPA . AEDIL . CVRVL . L. C. C. P. MILL. X.

Another inscription, also recording repairs of the time of Augustus, was found by Fabretti himself, in the Vinea Bartholomæi Virginii, two miles from the Porta Maggiore, between the ruins of the arcades of the Marcian and Claudian, and was preserved in a private museum:

IVL. TEP. MAR. IMP. CAESAR. DIVI . F. AVGVSTVS. EX. S. C. LXIII. P. CCXI.

[85] _Marrana_ is a general name for a running stream in the Campagna round Rome, probably a provincial word; but it is also the special name of this particular stream coming from Marino.

[86] “Tepula concipitur via Latina ad decimum milliarium, diverticulo euntibus ab Roma dextrorsus millium passuum duum ... inde suo rivo in urbem perducebatur.” (Frontinus, c. 8.)

[87] It is the building pointed out in guide-books as “The House of Cicero,” although there does not appear to be any historical ground for this name.

[88] “... ad milliarium ab urbe duo-decimum via Latina, _diverticulo_ euntibus ab Roma dextrorsus millium passuum duum alterius aquæ proprias vires collegit et Tepulæ rivum intercepit. Acquisitæ aquæ ab inventore nomen Juliæ datum est, ita tamen divisa erogatione, ut maneret Tepulæ appellatio.”—(Frontinus, c. 9.)

[89] “Præter caput Juliæ transfluit aqua quæ vocatur Crabra. Hanc Agrippa omisit.”—(Frontinus, c. 9.)

[93] Frontinus, c. 10.

[94] “Concipitur Virgo via Collatia ad milliarium octavum palustribus locis, _signino circumjecto_ continendarum scaturiginum causâ.” _Signinum_ is the particular kind of cement to hold water, always used to line the walls of the Aqueducts. It was not used after the time of the Empire, and the art of making it is said to be lost. It is the usual characteristic of the remains of an aqueduct.

[95] Frontinus, c. 10.

[96] Ibid., c. 22.

[97] This water is now usually called Acqua di Trevi, because its terminus is at the great fountain of Trevi. The sources are in the estate of Salone, as above described. It is still in use, and was long considered as the best water brought into Rome. The line now used is the one repaired and restored by the Popes; but, near Rome, it has been altered, probably after it had been damaged by the Goths or the Lombards. The old _specus_ passed through the Catacomb of S. Priscilla, in the Via Salaria, where it may be

seen. This is demonstrated by the _cippus_ of the aqueduct of Virgo, discovered in the Via Salaria, and so recorded by Muratori, Thes. Vet. Inscr., ccccxlii. 7, “Romæ in Via Salaria:”—

VIRG. TI . CÆSAR . AVG. PONTIF . MAXIM. TRIB. POT. XXXVIII. COS . V■. IMP. V■I■I■I■. I. P. CXL.

This inscription is A.D. 36.

It was then brought to the bank or _mœnia_ on which the wall of Aurelian was afterwards built near the Porta Salaria, and may be traced upon or in that bank under the present wall of Rome for about a mile. For a short distance, where this ground is low, it was carried on an arcade, of which there are remains under the wall built upon it. After this it goes on as far as the garden of the Villa Borghese and the French Academy, under which it now passes through the Pincian Hill.

[98]

This inscription was erected A.D. 46.

[99] There are remains of the Septa in the cellars under the houses on the west side of the Corso, in its lower part. These remains of the arcade are now chiefly underground, owing to the filling up of the great foss, called in this part Via Lata, because the wide foss under part of the Quirinal and of the Capitol had at one time been made into a wide street or place, on the eastern side of which is situated the Church of the “SS. Apostoli in Via Lata” and that of S. Maria in Via Lata on the western side, at the north-west corner. The great public building called the Septa went down the western side of this wide place from S. Maria to the Venetian Palace, with an arcade towards the street or place, of which many of the arches remain in the cellars. These arches under the church of S. Maria are absurdly called the house of S. Paul. They are visible also under the Palazzo Doria to the south of that church, and in other cellars.

[100] “Idem et Virginem adduxit ab octavi lapidis diverticulo duobus millibus pass. Prænestina Via.

“Juxta est Herculaneus rivus quem refugiens Virginis nomen obtinuit.” (Plinii Nat. Hist., lib. xxxi. c. iii. § 25.)

[101] Of this stream and its introduction into Rome in the twelfth century, an account will be found in the second part of this chapter.

Frontinus, c. 15 and 19.

[102] Frontinus, c. 11.

[103] Ibid., c. 18.

[104] Ibid., c. 71.

[105] The draining of the lakes in the hills round Rome is a great mistake, and very injurious to the health of the city. Such lakes are a wise provision of nature for collecting some of the surplus water in the rainy season, and preserving it for use in the hot and dry season, when the evaporation from the lakes helps to cool the air. The water also drawn from these lakes was most useful for the irrigation of the country round Rome, and watering the gardens in Rome itself, thereby promoting vegetation, which is essential for health in a hot and dry climate. It is well known that the leaves of plants and trees (more especially of deciduous trees) absorb _nitrogen_, which is the part injurious to human life, and give out _oxygen_, that portion which is beneficial to, and necessary for, human life. Where there is no vegetation, therefore, the climate cannot be healthy, and without water there can be no vegetation; for water is the necessary food of plants.

[106] The line of this subterranean aqueduct can also be traced by the wells descending into the _specus_, in the same manner as the Aqua Appia was traced in 1870, that is, by the bushes growing at the top of each of the wells, and generally enclosed by a wooden railing to prevent animals from falling into them.

[107] The rock in which the tunnel is cut is a sort of peperino, hard and rough, covered with a bed of clay.

[108] This lake, called Sabatina in the time of Frontinus, was called Anguillara in the Middle Ages, and is now called Bracciano, in both cases from the names of the proprietors. The great family of Anguillara had their origin from this village, of which they were the proprietors, and where they had a castle on the bank of the lake. The present proprietors are the Dukes of Bracciano. The lake

produces a great abundance of fish, especially a small fish much resembling the white-bait of London, at least when cooked.

[109] There is a small construction over this flood-gate, and at the back of it is this inscription:—

ACQVA PAOLA ALLA PRESA DELL' ACQVA ALSEATINA

[110] There are interesting remains of the Necropolis of this ancient city close to the fountain before mentioned, on each side of a deep ravine. On one side, there are nine chambers cut out of the rock on the edge of the cliff, the entrance being in the central chamber, with four others on either side of it. All are full of small square _columbaria_, of very early character. On the opposite side of the ravine, is a similar series of tombs, but in a less perfect state.

[111] There is _Opus Reticulatum_ of rude and early character (more like the _Opus Incertum_ of the Emporium than the mausoleum of Augustus) at the entrance of this passage, which is mentioned by Nibby. There is a stone-quarry also at the entrance, of the hard, dark-coloured stone used for making roads, and excellent for that purpose. This is the same stone that is called _selce_ or _silex_ in Rome, and seems to be similar to the hard lava under which Herculaneum is buried, and of which there are quarries near the tomb of Cecilia Metella.

[112] The persons employed by Mr. Parker went down to the bottom of this steep tunnel-passage to ascertain this.

[113] Nibby, Analisi storico-topografico-antiquaria della carta de' Dintorni di Roma, tom. i. Roma, 1837, 8vo. art. _Alsietina_.

[114] Cassio, Corso delle Acque, vol. i. p. 147.

[115] Nibby considers this a mistake, and is of opinion that the water was the Sabatina, not the Alsietina; but the mistake is made by Nibby himself, not by the engineers of Pope Paul, who certainly brought the water from the Lacus Alsietina and the other small lake above it (as mentioned on p. 50). By the draining of these lakes, the aqueduct is _now_ made to depend on the Lacus Alsietina only. The sources of the Alsietina are very different from those of the Sabatina. The former was taken by Augustus from the lake Alsietinus, now called Lago di Martignano, and the latter by Trajan from the sources between the lake Sabatinus and the villages of Vicarello, Bassano, and Oriolo. The Alsietina was at the lowest level of all the aqueducts, and the Sabatina at the highest. The first _specus_ was for the most part subterranean, and the other was carried upon arcades for part of its course.

[116] By the more usually received computation, the second year of Caligula would be A.U.C. 791; and the year of the consulship of Sulla and Titian, A.U.C. 805.

[117] It surpassed all the others _in quantity_, and being the highest, was used to supply the others when the water fell short; but the water was not so good for drinking.

[126] _In Subruino_ is the reading given in the text by Dederich. _In suo rivo_ is the reading adopted by Polenus, Jocundus, and other editors. A third reading has been suggested, "In Simbrivio," or in Simbruino, that is, referring to the Simbruine hills. This is the reading of Buecheler (1868), who follows verbatim the manuscript of Monte Cassino. The reading, however, bears little upon the evidence.

[127] _Herculaneus Rivus._ This is not the same _Herculaneus Rivus_ as the one mentioned by Frontinus in connection with the Anio Vetus, in ch. 19. The same name is given in these places to different streams, all strong and rapid.

[130] Ibid., c. 91.

[131] Frontinus, c. 76.

[132] “At ex alia parte Anio in monte Trebanorum ortus lacus tres amœnitate nobiles, qui nomen dedere Sublaqueo defert in Tiberim.” (Plinii Nat. Hist., iii. 109.)

[133] The inhabitants of Filettino probably belonged to the tribe of the Trebani, or of Trebula, who were located in the neighbourhood of Trevi, where was a Roman colony and principality. Inscriptions giving the names and titles of Augustus, Septimius Severus, and Commodus, were found here, and are published by Signor Gori in his Trattato dell’ Acqua Marcia, &c., 12mo., 1866, p. 37. Another inscription at Anagni, on the front of the Governor’s palace, gives the name of Publius Vecellius, curator of the Republic of the Trebani.

Martial mentions the Treba Augusta of Frontinus, under the name of Trebula:

“Trebula nos genuit, commendat gratia duplex Sive levi flamma, sive domamur aqua.” (Lib. v. epigr. 65, and lib. xiii. epigr. 33.)

Livy also mentions it: “Eodem anno Arpinatibus Trebulanisque civitas data.” (Livii Hist., x. 1.)

[134] IMP CAESARIS NERVAE TRAIA(_ni_) ... OP(T)IMI AVG GERMANIC DACICI.

[135] “Lacus monasterii ad nihilum redactus, quia duo monachi levaverunt duo lapides, qui fuerunt firmati cum aliis petris; et sic aqua destruxit.” (Chronicon Sublacense, apud Muratori, Rer. Ital. Script., tom. xxiv. col. 962, D.) The author of this Chronicle was living in the year 1390.

[136] Gruter, Inscriptiones, p. clv. 4.

[137] Probably the text of Frontinus here is corrupt, because the Piscina Limaria and the _specus_ of Claudius are at the forty-sixth mile on the Via Sublacensis, “ad milliarium quadragesimum _secundum_,” for “Ad milliarium quadragesimum _sextum_.”

[138] Dr. Fabio Gori, who is a native of Subiaco, claims the credit of being the first person to point out what this great work of Trajan really was. He also states that the Rivus Herculaneus, rising at thirty-eight miles on the Via Sublacensis, must have been a clear stream, which he finds on the left side of the river, opposite to the lake of S. Lucia and to this source of the aqueduct of the Claudia, called Acqua dell’ Arco, or water of the aqueduct.

[139] Frontinus, c. 72.

[140] The _piscina_ made in one of the towers in the wall at the point where it enters Rome, has the four chambers visible, the inner wall of the tower having been destroyed.

[141] Inscriptions on the Porta Maggiore:—

These inscriptions shew that considerable repairs were made by Vespasian and Titus to the Claudian aqueducts; and these repairs were continued by their successors, Nerva, Trajan, and Hadrian. Many parts and branches belong to the time of these Emperors.

[142] Vide “Delle vere Sorgenti dell’ Acqua Marcia,” &c., “trattato di Fabio Gori.” Roma, 1866. An admirable map shewing the sources and the line of each of the Aqueducts, has been made for me under the direction of the author.

[143] Frontinus (c. 15) gives the length of the _specus_ of the Anio Novus as 58 miles and 700 _passus_; add to this the length of the Piscina Limaria and of the three lakes, and we have the distance of 62 miles from Rome for this aqueduct.

[144] “Qui colles, (mons Cœlius et Aventinus,) priusquam Claudia perduceretur, utebantur Marcia et Julia. Sed postquam Nero Imperator Claudiam, opere arcuato altius exceptam, usque ad templum Divi Claudii perduxit, ut inde distribueretur, priores non ampliatæ, sed omissæ sunt: nulla enim castella adjecit, sed iisdem usus est, quorum, quamvis mutata aqua, vetus appellatio permansit.” (Frontinus, c. 76)

[145] The large square part of the Cœlian Hill, with scarped cliffs round three sides of it and part of the fourth, which had probably been originally the _arx_ or citadel of the Cœlian when that was a separate fortress, and on which Claudius erected some great public building with a temple, is marked on the modern maps of Rome as a _castellum aquæ_: this is an exaggeration. A _specus_ runs along the western side opposite to the Palatine in the wall, and goes straight towards the Colosseum, and there are remains of a piscina of the first century at the north-west corner of the Claudium, near the Colosseum, and the Meta Sudans; but this is at a low level, and does not agree with there being a large reservoir under the whole of that space.

[146] Frontinus did not live to see this completed.

[147] Cap. 86, 91, 92, and 105.

[148] These are at present almost hid by modern houses built up against them, but it is expected that these modern erections will shortly be removed. The remains of the bridge project at a right angle from the palace of Domitian. It had the aqueduct at the top at a very high level, and a road for horses by the side of it at a lower level, as at the Ponte Lupo, Ponte S. Antonio, and other bridges of the aqueducts.

[149] These imperial “Edicts” or “Decrees,” or Laws and Constitutions, have been published in various works. The later ones relating to this subject are published by Polenus, in the Appendix to his edition of Frontinus, 4to. Pataviæ, 1722; and by Rondelet, as a supplement to Frontinus, who had published those issued up to his time. See Commentaire de Frontin sur les aqueducs de Rome, 2 parts, 4to. and atlas folio, Paris, 1802; and Rondelet, Opere, 6 vols. 4to. Mantova, 1841, tom. vi. p. 117, &c.

[150] This water was celebrated for its coolness, as mentioned in the life of Alexander Severus by Lampridius, c. 30.

[151] The new company for bringing these springs into Rome again, under the name of the Aqua Marcia-Pia, has been obliged to make compensation to the town of Tivoli for the possible injury to the manufactories established there, which depend upon the force of the water, although the damage was in a great degree imaginary. This new aqueduct brings the water of the Marcia only. The water is nearly of the same quality as that of the Claudia, and is still found as cool as it was in the time of the early Empire, notwithstanding that it is brought into Rome in metal pipes for the last ten miles. A number of shops for the sale of this cool water have been opened in different parts of Rome. Nature never changes, and the same qualities of particular springs which prevailed two thousand years ago, prevail still. It is said by persons who have witnessed the experiment tried, that in the hot summer weather of Italy, when the thermometer of Fahrenheit stands above 100, the contrast between the heat of the air and the coldness of the water is so great that if a glass tumbler is suddenly put into the water near its source, the glass will break in the same manner as a glass tumbler will break in England if boiling water is poured into it in frosty weather.

[152]

In the above the _m_ = to the Roman mile = 1,000 Roman passus. _p_ = to the Roman passus = 5 Roman feet. The Roman mile (_mille passus_) = 1,618 English yards. The Roman passus = 4 English feet 10·428 inches. The Roman foot = 11·6496 English inches.

[153] The Roman foot was nearly as long as our own, being, according to the most accurate estimate, about 11½ English inches (11.6496).

[154] Frontinus, c. 24.

[155] Dederich reads “unciæ in popularibus rationibus adhuc observantur,” which seems better. The _uncia_ was an Italian, the _digitus_ a Greek measure.

[156] It is evident from his making the square of the diameter ³⁄■■ greater than the area of the circle drawn upon the same diameter, that he takes the ratio of the area to the diameter as ¹¹⁄■■ to diameter 1. This is very near to the truth. The converse as given by him also agrees, as is seen by ¹¹⁄■■ + ³⁄■■ of ¹¹⁄■■ = 1.

[157] Frontinus, c. 65.

[158] It is of little consequence, but perhaps it may be interesting to know more accurately the result of the calculation. If we take 1.25 as the diameter of the quinary, and multiply the square of this by 0.7854 (the corrected ratio), we obtain the result in square digits, 1.22718. This multiplied by the 1825 gives 2239.6, that is, the result within one digit as given by Frontinus.

[159] An Anglo-Roman company has now (1872) brought the Aqua Marcia (III.) again into Rome at so high a level, that it will supply cisterns at the tops of the houses. At present a number of ingenious contrivances are in use for sliding small buckets of water from the well or reservoir in the courtyard, to the upper windows and galleries round the central courts of the old houses or palaces. These reservoirs, whether large or small, are called _lacus_ by Frontinus and in the Regionary Catalogue.

[160] The expression _reddita_ would imply that originally the Marcian had supplied the Aventine, and that, it having been superseded by the Claudian, it was now restored and used in addition to the other. See the extract—Frontinus, c. 76.

[161] Frontinus, c. 89.

[162] Ibid., c. 90, 91.

[163] The division of the surface water from the sewerage, in the question of the drainage of large towns, is meeting with much favour, as it appeals to reason that what is good for the purposes of manure, is destructive to the healthy condition of the river, while the surface water, which finds its proper place in the river, interferes with the proper distribution of sewage. In Rome, there is frequently a small _specus_ or channel for pure water, contrived in the vault or upper part of the great _cloacæ_ or drains for the refuse water. Could not the same plan be adopted in London with advantage? But while this is canvassed, it seems singular that we hear little of the division of the _supply_, which, on the same principle, should certainly be divided. There are several towns so situated, that a fair supply of pure water might be brought very acceptable for drinking, but not in sufficient quantities to be applicable to other offices. The words of Frontinus are very concise and pointed:—

“Marciam ut ipsam, splendore et frigore gratissimam, balneis ac fullonibus et relatu quoque fœdis ministeriis deprehenderimus servientem. Omnes ergo discerni placuit, tum singulas ita ordinari, ut in primis Marcia potui tota serviret, et deinceps reliquæ secundum suam quæque qualitatem aptis usibus assignarentur, sicut Anio Vetus pluribus ex causis, quo inferior excipitur minus salubris, in hortorum rigationem atque in ipsius urbis sordidiora exiret ministeria.” (Frontinus, c. 91, 92.)

[164] See C. C. J. Bunsen’s _Beschreibung der Stadt Rom._ Stuttgart und Tübingen, 1830, 8vo.

[165] The mother of Cola di Rienzi was one of those who gained a livelihood by selling water in the streets.

[166] The ruined _castellum_ at the Porta Furba, two miles from Rome, (previously mentioned,) seems to have been of this description; it rises considerably above the level of the conduits, vertically, as if either for water or air to rush up it.

[167] Cassiodori Var., lib. vii. 6, and iv. 31.

[168] Procopius, de Bello Gothico, lib. i. c. 19.

[169] This is shewn by the large corbels in the wall on the bank of the river at this point, opposite to the Cloaca Maxima, which are pierced with holes through them, in which a pole was placed to attach the chain. These corbels remain perfect on the western side; on the eastern side, they have been destroyed, or covered over by medieval houses. Those which remain are carved into the form of gigantic lions’ heads, of the character called Etruscan, but are of the time when the Port of Rome was made in the Tiber, B.C.

[172] In the life of Hadrian by Spartianus (c. 20), we are told that a number of aqueducts were made in his time and called after him. But his name is not retained in the Regionary Catalogue.

[173] Frontinus, c. 88.

[174] We have seen before that Eadmer mentions the malaria in Rome as early as the twelfth century. (Historiæ Novor., lib. ii. ad calcem S. Anselmi operum, p. 51, D. Lut. Par. 1675, fol.) In the following century, the author of “Sir Bevis of Southampton” gives a strange account of the fevers arising from the Pontine Marshes into the Campagna di Roma. There were, says he, two dragons there; one having fled to Toscan [Tusculum?],—

“That other dragoun ’is flight nome (took) To Seinte Peter ’is brige of Rome: Thar he schel leggen ai (lay for ever) Til hit come domesdai; And everi seve yer ones, Whan the dragoun moweth (moves) ’is bones, Thanne cometh a roke (reke, smoke) & a stink Out of the water, under the brink, Than men therof taketh the fevere, That never after mai he kever (recover); And who that n’el nought leve (believe) me, Wite (know, inquire) al pilgrimes that ther hath be; For thai can tell yow, I wis, Of that dragoun how it is.”

(Weber, “Metrical Romances,” &c., vol. iii. p. 315. Edinburgh, 1810, 12mo.)

[175] The fragment of an inscription relating to this aqueduct was found near Gabii, and is described by E. Q. Visconti in his _Monumenti Gabini_, Roma, 1797, 8vo. maj., p. 14.

IMP. CAESAR DIVI TRAiani (Parthici filius Trajanus Hadrianus) AVG. PONTIF[ex Maximus] AQVAE DVCTVM GABINIS . . . QVAM . . . . .

The second line appears to be an interpolation of the editor, but this is not material. The aqueduct begun by Nerva was not finished till the time of Hadrian. The aqueduct of Gregory XIII. and Sixtus V. (Felice) (A.D. 1572-1590) receives the water of this aqueduct, but at Colonna other springs are collected and added to it; this was the work of Fontana.

[176] The Torre Pignattara is so called from the earthenware pots (_pignatte_) of which the vault was built. Other remains of buildings of importance have been found near the Mausoleum of S. Helena, and there is some reason to believe that another imperial villa was situated there during the first three centuries.

[177] Some say the popular name is _Torre de Scavi_, or of the excavations from some great works of excavation made there in the twelfth century.

[178] Note f, p. 88. “Aquarum ductus etiam infinitas hoc nomine (Hadriani) nuncupavit.” (Spartianus in Hadriano, c. 20.)

[179] It is immediately opposite to the Palatine, and there is a remarkably fine view from the portion of the _specus_ that remains, the vault of which has been removed, and it is used as a terrace.

[180] Mémoire sur les fouilles exécutées à Santa Sabina. Paris, Imprimerie Impériale, 1868, 4to.

[181] EX . FIG . . . . AEAM . . AUGVS . RUST . IT . ET . AQVI . . (Ap. Fea, Fasti Consul., p. cxviii. No. 62.) Junius Rusticus et Aquilinus were Consuls, temp. Marci Aurelii, A.D. 162.

[182] Commodus was emperor from 180 to 192, but was slain at the early age of 31; and it is probable that this great work was left unfinished, and was completed by his successor, Septimius Severus. In the Regionary Catalogue they are mentioned together, and

there was probably no division between them.

[183] It was usual to take advantage of the _castella aquæ_ of the great aqueducts to construct bath-chambers of various kinds, both for hot and cold and swimming baths.

[184] This is also mentioned in our account of the Anio Vetus (II.), as the branch at the second mile from Rome according to Frontinus. From the low level, it is more probable that this branch came from the Anio Vetus than from the Marcia, and an itinerant pilgrim of the eighth or ninth century may have been mistaken on this point.

[185] This was probably the branch that now runs under the Via dei Condotti. The main line to supply the Thermæ of Agrippa has been traced beyond the fountain of Trevi to the Piazza di S. Ignazio, very near the Pantheon, which was the entrance-hall to these _thermæ_. Those of Nero and Alexander Severus were more to the north.

[186] See Aqueduct XI. Trajana.

[187]

HERCVLI . CONSERVATORI INVICTO . COMITI D. N. SEVERI . ALEXANDRI PII . VICTORIS . SEMPER AVG. AC. OPTIMI . PRINCIPIS M. AVRELIVS . PRISCILLIANVS V. C. CVRATOR . NYMPHAEI DEVOT . NVM . M. Q. E.

[188] The great Thermæ of the third century in the Esquiliæ, where the building known as the Minerva Medica stands, and to which the other building, called after the Trophies of Marius, is supposed to have been the entrance; this has been identified as a Nymphæum of Alexander Severus, by the representation of it on one of his coins.

[191] There is a subterranean reservoir under it, and there are several other subterranean reservoirs in this ground.

[192] This great Pantheum was a temple of all divinities, and also a hall for the men, being connected by a large vaulted passage at the back with the _thermæ_, of both of which there are visible remains.

[193] This spring is considered by some authors as the one source of the river Almo; but it is only one of many, and it falls into the deep bed of the river, coming from some miles beyond that point.

[194] In the valley of the Caffarella, a stone _specus_ has been made by the side of the natural bed of this branch; it is open at the top, has lochs in it, and is on a higher level than the natural stream. The object of this was obviously to keep a supply of water from the springs in dry weather.

[195] The two arches of the Porta Metronia remain, both built of brick of the time of Aurelian. The outer arch is visible in the city wall; the inner one is concealed by a medieval tower built up against it. In the year 1871, Signor Rosa made a new gate on the east side of the Porta Metronia for his carts to pass through, in which the earth, excavated from the Palatine, is carried out into the meadow beyond, outside of the walls. This is certainly better than continuing to fill up the valley between the Aventine and the Pseudo-Aventine, and thereby concealing more of the Wall of the Kings under S. Balbina and burying more of the Aqua Appia, than has already been done under his orders.

[196] Cicero, Epist. ad Q. Fratrem, lib. iii. ep. 7.

[197] “Hic etiam derivavit aquam de antiquis Formis, et ad Portam Lateranensem conduxit, ibique lacum pro adaquandis equis fieri fecit. Plurima quoque molendina in eadem aqua construxit, et multas vineas cum fructiferis arboribus secus ipsum lacum plantari studiosissimè fecit.” (Muratori, Rerum Italic. Script., tom. iii. p. 420, col. 2, E.)

[198] “Aquam ad Urbem reduxit, molendina cum vineis juxta lacum aptavit,” &c. (Pandolphus Pisanus, ibid., p. 419, col. 1, E.)

[200] See Aqueduct XI.

[201] The Pope insisted on the work being completed at the time originally fixed, notwithstanding that the blunder of his engineer made it necessary to rebuild the whole arcade for seven miles.

[202] “Nunc autem in urbem influunt: 1. Aqua Appia, 2. Anio Vetus, 3. Marcia, 4. Tepula, 5. Julia, 6. Virgo, 7. Alsietina (quæ eadem vocatur Augusta), 8. Claudia, 9. Anio Novus.” (Frontinus, 4.)

[203] Id., c. 19.

[204] See Aqueduct III.

[205] Frontinus, c. 15, in both cases called by him, Herculaneus.

[206] Frontinus, c. 12.

[207] Id., c. 5.

[208]

“Quid loquar aërio pendentes fornice rivos, Qua vix imbriferas tolleret Iris aquas? Hos potius dicas crevisse in sidera montes, Tale giganteum Græcia laudat opus. Intercepta tuis conduntur flumina muris; Consumunt totos celsa lavacra lacus.”

(Cl. Rutilii Itiner., l. 1, v. 97. and following.)

[209] “In formis autem Romanis utrumque præcipuum est ut fabrica sit mirabilis et aquarum salubritas singularis. Quod enim illuc flumina quasi constructis montibus perducuntur, naturales credas alveos soliditates saxorum, quando tantus impetus fluminis tot sæculis firmiter potuit sustineri. Cavati montes plerunque subruunt, meatus torrentium dissipantur, et opus illud veterum non destruitur, si industria suffragante servetur.”—(Cassiodori Variar., l. vii. c. 6.)

[210] It is possible that the number of nineteen was made up by adding the different branches that supplied the Thermæ of the later Emperors, (Septimius) Severus, Antoninus, Alexander (Severus), (Aurelius) Commodus, Constantinus.

To these must now be added the two modern aqueducts, the Marrana and Aqua Crabra [XVII.], united and brought through Rome in the twelfth century in the bed of that branch of the river Almo, and the Aqua Felice [XVIII.], made in the sixteenth; also the Aqua Marcia-Pia, made between 1860 and 1870, which now brings the water of the Aqua Marcia into Rome by a different line.

[211] This was also the principal gate of the Sessorian Palace, and was sometimes called the Porta Sessoriana.

[212] See Diagrams III. and XIX.

[213] See the Plans and Sections of this, Plate XXI.

[214] The water pumped out by the steam-engine employed by Signor Rosa was always good clear drinking water, and had all the appearance of coming from an aqueduct; it was sent along an open channel the whole length of the Colosseum, and made a great swamp round the arch of Constantine for several months in the spring of 1875, the outlet for it being made on the outer side of the drain under that arch, which had been constructed by the Municipality about 1866. At last it was observed that an aperture into that drain might easily be made on the inner side, and so avoid the swamp in the road, and washing the foot of the arch. Soon after this the steam-engine was stopped on account of the enormous expense of it, after it had gone on for more than a year, always pumping out good drinking water, and sending it to waste.

[215] This article will be found in the _Annales de l’Institut de Correspondance Archéologique_, 1873.

[216] Near the Porta Maggiore, and under the arches of Nero. There are two large reservoirs close together in this vineyard, probably the Gemelli of Frontinus.

[217] _Descending_ from the reservoir into the old _specus_ under the arches of Nero.

[218] The Aqua Marcia was brought again into Rome by a new water company in the year 1870, after several years of very arduous work, and overcoming many difficulties. The company who made this great aqueduct consisted chiefly of English shareholders, with a mixture of French and Italian. It was long under the direction of the late Mr. Shepherd, an Englishman, whose loss was much regretted in Rome, and latterly under a Belgian engineer.

[219] See Frontinus de Aqueductibus, c. 5.

[220] There is a large and deep reservoir for it near the arch of Dolabella, under the garden of the Villa Mattei, now called the Villa Cœlimontana, and from thence it passed, still underground, to the cliff of the Cœlian, opposite to the Aventine. A short tunnel was made from this deep reservoir to a Nymphæum under the Cœlian, now S. Stefano Rotondo, called of Septimius Severus. The ruins of it are shewn in 895; a _specus_ has been traced from one to the other.

[221] See Frontinus de Aqueductibus, c. 6.

[230] Cohen. Méd. Imp. Alex. Sev., (Nos. 239, 334).

[231] This water is not mentioned in the Regionary Catalogue, and its whole history appears doubtful. Some think the name is a corruption of Argentina, the short stream that rises in the Lupercal or Wolf's Cave, under the north-west corner of the Palatine, as before mentioned.

[232] These sources are on the cliffs above the river Anio, at from five seven miles from Rome, and two miles from Ponte Nono, in swampy meadows called "the meadows of Lucullus," and some in old stone quarries.

[Pg 1] PREFACE

In the following pages I have endeavored to present a comprehensive and general view of the material side of the universe. Instead of trying myself to tell the story of the universe, I have gone to the works of acknowledged weight and authority in this line of research and selected from them extracts of a popular character, especially those that are entertaining as well as merely instructive. The average reader is frequently repelled from the study of the sciences by the dry treatment adopted by those who try to instruct him. He cares little for laws, theories, or affinities; and he can not help being bored by attempts to make him understand classifications with their long lists of words manufactured from the names of modern celebrities or non-entities and roots from dead languages. I have therefore kept constantly in mind the person who seeks entertaining knowledge, and not the scientific specialist. I have tried to avoid all technicalities wherever possible.

Of late years, in fact ever since the foundation of the British Association, there has been a constantly increasing interest in the wonders of nature; and the specialist has responded to this popular interest in his scientific labors by speaking in language that an intelligent child can comprehend. People as a rule prefer to read of the habits, instincts, intelligence, and movements of animals and plants, rather than of their organs and structure. Thus the study of Natural History has received a great impetus from the writings of such men as Darwin and Lubbock; and Astronomy has been rendered more attractive to the lay reader by Flammarion, Gore, Proctor, and Ball. Every traveler who[2] returns from remote or hitherto unknown Arctic or Torrid Zones has something fresh to tell us of the phenomena and life of our universe, which adds fresh stimulus to the popular interest in the Natural Sciences.

The Story of the Universe naturally falls under the following four heads:

First, the bodies moving in infinite space, including stars, dark and lucid, planets, nebulæ, comets, and meteors.

Second, the Earth, considered as a separate world and the only one of which we have precise detailed knowledge. In this chapter we learn of the past of our globe from the evidence afforded by the rocks of which its crust is composed. The varying conformations of its present surface are described, as is its atmospheric envelope and attendant phenomena. The ocean and its movements and depths are likewise fully considered.

Third, the Earth's Garment—its flora. In this chapter we are told of the wonders and beauties of plant-life, its development and distribution.

Fourth, the Earth's Creatures. Here we have a general view of animal life, from the mighty mammoth to the fairy fly: even the beings visible only to the microscope are not forgotten. Special attention is also paid to man, from his origin to the present day.

I have made the selections from authentic editions of the writings of the scientists; and have taken no liberties with the text, with the exception of occasional cutting.

In the Introduction I have given a short sketch of the development of the Natural Sciences, from the dawn of written history to the present day.

E. S.

New York, March, 1905.

[3] INTRODUCTION

The knowledge of the Natural Sciences among the Greeks and Romans was derived principally from the Egyptians and Babylonians. The Phœnicians in their voyages, also, necessarily paid considerable attention to Astronomy. Their Cynosura consisted of the tail of the Little Bear, by which they steered. The great names in Greek Astronomy are Aratus, Hipparchus, and Ptolemy.

From the fancies of Astrology, in which the early Arabs largely indulged, and which, though discountenanced by Mahomet himself, have never been wholly abandoned by their descendants, a not unnatural transition, led to the study of Astronomy. Under the patronage of the Abbaside Caliph Al-Mamun (813-833 A. D.) this science made rapid progress.

Astronomy was zealously studied in the famous schools of Bagdad and Cordova.

The Almagest, or System of Astronomy, by Ptolemy, was translated into Arabic by Alhazi and Sergius as early as 812. In the Tenth Century, Albaten observed the advance of the line of the apsides in the earth's orbit; Mohammed-ben-Jeber-al-Batani, the obliquity of the ecliptic; Alpetragius wrote a theory of the planets; and Abul-Hassan-Ali, on astronomical instruments. The obliquity of the ecliptic, the diameter of the earth, and even the precession of the equinoxes, were then calculated with commendable accuracy; and shortly after, Abul-Mezar's Introduction to Astronomy and his Treatise on the Conjunction of the Planets, with the Elements of Al-Furjanee (though this last author was largely indebted to the Egyptian labors of Ptolemy), proved that the caliph's liberality had been well bestowed.[4] But Al-Batinee, a native of Syria (879-920 A. D.), surpassed all his predecessors in the nicety alike of his observations and computations. Geber, at Seville, constructed (1196 A. D.) the first astronomical observatory on record; and Ebn-Korrah in Egypt proved by his example that the Arabs could be even better astronomers than the Greeks.

Ulug Bekh, grandson of the great Tamerlane, was a diligent observer. He established an academy of astronomers at Samarcand, the capital of his dominions, and constructed magnificent instruments. Ulug Bekh, too, made a catalogue of the fixed stars—the only one that had been compiled since that of Hipparchus, sixteen centuries previously.

Gradually, by their intercourse with civilized nations, the Arabian conquerors were themselves subjected to the humanizing influence of letters, and, after 749 A. D., or during the reign of the Abassides, literature, arts, and sciences appeared, and were generously fostered under the splendid sway, first of Almansor (754-775), and afterward of the celebrated Harun-al-Raschid (786-808). Learned men were now invited from many countries and remunerated for their labors with princely munificence; the works of the best Greek, Syriac, and old Persian writers were translated into Arabic, and spread abroad in numerous copies. The Caliph Al-Mamun, who reigned from 813 to 833, offered to the Greek emperor five tons of gold and a perpetual treaty of peace on condition that the philosopher Leo should be allowed to give instruction to the former. Under the same Caliph the famous schools of Bagdad, Basra, Bokhara, and Kufa were founded, and large libraries were collected in Alexandria, Cairo, and Bagdad. The school

of Cordova in Spain soon rivaled that of Bagdad, and in the Tenth Century the Arabs were everywhere the preservers and distributers of knowledge.

Pupils from France and other European countries repaired to Spain in great numbers, to study mathematics and medicine under the Arabs. There were fourteen academies,[5] with many preparatory and upper schools, in Spain, and five very considerable public libraries; that of the Caliph Hakem containing, as is said, more than 600,000 volumes.

In Geography, History, Philosophy, Medicine, Physics, and Mathematics the Arabians rendered important services to science; and the Arabic words still employed in science—such as algebra, alcohol, azimuth, zenith, nadir, with many names of stars, etc. (see The Arabian Heavens, pages 106-120 of Vol. I)—remain as indications of their influence on the early intellectual culture of Europe. But Geography owes most to them during the Middle Ages. In Africa and Asia, the boundaries of geographical science were extended, and the old Arab treatises on geography and works of travels in several countries by Abulfeda, Edrisi, Leo Africanus, Ibn Batuta, Ibn Foslan, Ibn Jobair, Albiruni the astronomer, and others, are still interesting.

The structure of the earth received little attention from the ancients; the extent of its surface known was limited, and the changes upon it were neither so speedy nor violent as to excite special attention. The only opinions deserving to be noticed are those of Pythagoras and Strabo, both of whom observed the phenomena which were then altering the surface of the earth, and proposed theories for explaining the changes that had taken place in geological time. The first held that, in addition to volcanic action, the change in the level of sea and land was owing to the retiring of the sea; while the other maintained that the land changed its level, and not the sea, and that such changes happened more easily to the land below the sea because of its humidity.

From the fall of the Roman empire, during the Dark Ages, the physical sciences were neglected. In the Tenth Century, Avicenna, Omar, and other Arabian writers commented on the works of the Romans, but added little of their own.

Geological phenomena attracted attention in Italy in the Sixteenth Century, the absorbing question then being[6] as to the nature of fossils; only a few maintained that they were the remains of animals. Two centuries elapsed before the opinion was generally adopted.

Aristotle was the first who collected, in his work On Meteors, the current prognostics of the weather. Some of these were derived from the Egyptians, who had studied the science as a branch of Astronomy, while a considerable number were the result of his own observation. The next writer upon this subject was Theophrastus, one of Aristotle's pupils, who classified the opinions commonly received regarding the weather under four heads, viz., the prognostics of rain, of wind, of storm, and of fine weather. The subject was discussed purely in its popular and practical bearings, and no attempt was made to explain phenomena whose occurrence appeared so irregular and capricious. Cicero, Virgil, and a few other writers also wrote on the subject; but the treatise of Theophrastus contains nearly all that was known down to comparatively recent times. Partial explanations were attempted by Aristotle and Lucretius, but their explanations were vague, and often absurd.

In this dormant condition meteorology remained for ages, and no progress was made till proper instruments were invented for making real observations with regard to the temperature, the pressure, the humidity, and the electricity of the air.

Solomon spoke of "trees, from the cedar in Lebanon even to the hyssop that springeth out of the wall." There is reason also to believe that Zoroaster devoted some attention to plants, and that this study early engaged some of the philosophers of Greece. The oldest botanical work which has come down to us is that of Theophrastus, the pupil of Aristotle, who flourished in the fourth century B. C. His descriptions of plants are very unsatisfactory, but his knowledge of their organs and of vegetable physiology may well be deemed wonderful. It was not, indeed, till after the revival of letters in Western Europe, that it was ever again studied as it had been by him. About four hundred[7] years after Theophrastus, in the First Century of the Christian era, Dioscorides of Anazarbus, in Asia Minor—a herbalist, however, rather than a botanist—described more than 600 plants in a work which continued in great repute throughout the Middle Ages.

About the same time, the elder Pliny devoted a share of his attention to Botany, and his writings contain some account of more than 1,000 species, compiled from various sources and mingled with many errors. Centuries elapsed without producing another name worthy to be mentioned. It was among the Arabians that the science next began to be cultivated, about the close of the Eighth Century. The greatest name of this period is Avicenna. Among the Arabs, Botany, like Chemistry, was chiefly studied as subsidiary to medicine; but as an adjunct to the old herbal pharmacopœia, it received close attention. The principal mercurial and arsenical preparations of the materia medica, the sulphates of several metals, the properties of acids and alkalies, the distillation of

alcohol—in fine, whatever resources chemistry availed itself of up to a very recent date—were, with their practical application, known to Er-Razi and Geber. In fact, the numerous terms borrowed from the Arabic language—for instance, alcohol, alkali, alembic, and others—with the signs of drugs and the like, still in use among modern apothecaries, remain to show how deeply this science is indebted to Arab research.

Aristotle seems to have been the first to study Zoology. Some of the groups he established still retain their place in the most modern classifications. His two great sections of the Animal Kingdom consisted of Enanima (red blood) and Anima (having a circulation of colorless fluid). Ælian and Pliny wrote on the subject, but they indulged largely in fables. There was little advance in the science during the Dark and Middle Ages. The Bestiaries were written for the sake of moral teaching, and the animals had to behave with that end in view. Albertus Magnus is the only famous name in this department before the revival of learning.

[8]

The shining light of the Thirteenth Century was Roger Bacon. His Opus Majus is “at once the Encyclopædia and the Novum Organum of the Thirteenth Century.” In this, besides other branches of scientific research, he devotes a rapid examination to questions of Climate, Hydrography, Geography, and Astrology. Scientific research, however, was out of date, and from the educated world Roger Bacon received small recognition. His writings earned only a prison from his own Order, and he died, in his own words, “unheard, forgotten, buried.”

The Revival of Learning, commonly known as the Period of the Renaissance, naturally entailed renewed interest in the sciences as well as the arts. Green gives a comprehensive view of it:

“The last royalist had only just laid down his arms when the little company who were at a later time to be known as the Royal Society gathered round Wilkins at Oxford. It is in this group of scientific observers that we catch the secret of the coming generation. From the vexed problems, political and religious, with which it had so long wrestled in vain, England turned at last to the physical world around it, to the observation of its phenomena, to the discovery of the laws which govern them. The pursuit of physical science became a passion; and its method of research, by observation, comparison, and experiment, transformed the older methods of inquiry in matters without its pale. In religion, in politics, in the study of man and of nature, not faith but reason, not tradition but inquiry, were to be the watchwords of the coming time. The dead-weight of the past was suddenly rolled away, and the new England heard at last and understood the call of Francis Bacon.

“Bacon had already called men with a trumpet-voice to such studies; but in England at least Bacon stood before his age. The beginnings of physical science were more slow and timid there than in any country of Europe. Only two discoveries of any real value came from English research before the Restoration; the first, Gilbert’s discovery of terrestrial magnetism in the close of Elizabeth’s reign; the next, the great discovery of the circulation of the blood, which was taught by Harvey in the reign of James. Apart from these illustrious names England took little share in the scientific movement of the continent; and her whole energies seemed to be whirled into the vortex of theology and politics by the Civil War. But the war had not reached its end when a little group of students[9] were to be seen in London, men ‘inquisitive,’ says one of them, ‘into natural philosophy and other parts of human learning, and particularly of what hath been called the New Philosophy,... which from the times of Galileo at Florence, and Sir Francis Bacon (Lord Verulam) in England, hath been much cultivated in Italy, France, Germany, and other parts abroad, as well as with us in England.’ The strife of the time indeed aided in directing the minds of men to natural inquiries. ‘To have been always tossing about some theological question,’ says the first historian of the Royal Society, Bishop Sprat, ‘would have been to have made that their private diversion, the excess of which they disliked in the public. To have been eternally musing on civil business and the distresses of the country was too melancholy a reflection. It was nature alone which could pleasantly entertain them in that estate.’ Foremost in the group stood Doctors Wallis and Wilkins, whose removal to Oxford, which had just been reorganized by the Puritan Visitors, divided the little company into two societies. The Oxford society, which was the more important of the two, held its meetings at the lodgings of Dr. Wilkins, who had become Warden of Wadham College, and added to the names of its members that of the eminent mathematician Dr. Ward, and that of the first of English economists, Sir William Petty. ‘Our business,’ Wallis tells us, ‘was (precluding matters of theology and state affairs) to discourse and consider of philosophical inquiries and such as related thereunto, as Physick, Anatomy, Geometry, Astronomy, Navigation, Statics, Magnetics, Chymicks, Mechanicks, and Natural Experiments: with the state of these studies, as then cultivated at home and abroad. We then discoursed of the circulation of the blood, the valves in the venæ lacteæ, the lymphatic vessels, the Copernican hypothesis, the nature of comets and new stars, the satellites of Jupiter, the oval shape of Saturn, the spots in the sun and its turning on its own axis, the inequalities and selenography of the moon, the several phases of Venus and Mercury, the improvement of telescopes, the grinding of glasses for that purpose,

the weight of air, the possibility or impossibility of vacuities, and Nature's abhorrence thereof, the Torricellian experiment in quicksilver, the descent of heavy bodies and the degree of acceleration therein, and divers other things of like nature.'

"The other little company of inquirers, who remained in London, was at last broken up by the troubles of the Second Protectorate; but it was revived at the Restoration by the return to London of the more eminent members of the Oxford group. Science suddenly became the fashion of the day. Charles was himself a fair chymist, and took a keen interest in the problems of navigation. The Duke of Buckingham varied his freaks of riming, drinking,[10] and fiddling by fits of devotion to his laboratory. Poets like Dryden and Cowley, courtiers like Sir Robert Murray and Sir Kenelm Digby joined the scientific company to which in token of his sympathy with it the King gave the title of 'The Royal Society.' The curious glass toys called Prince Rupert's drops recall the scientific inquiries which, with the study of etching, amused the old age of the great cavalry leader of the Civil War. Wits and fops crowded to the meetings of the new society. Statesmen like Lord Somers felt honored at being chosen its presidents. Its definite establishment marks the opening of a great age of scientific discovery in England. Almost every year of the half century which followed saw some step made to a wider and truer knowledge. Our first national observatory rose at Greenwich, and modern astronomy began with the long series of astronomical observations which immortalized the name of Flamsteed. His successor, Halley, undertook the investigation of the tides, of comets, and of terrestrial magnetism. Hooke improved the microscope, and gave a fresh impulse to microscopical research. Boyle made the air-pump a means of advancing the science of pneumatics, and became the founder of experimental chymistry. Wilkins pointed forward to the science of philology in his scheme of a universal language. Sydenham introduced a careful observation of nature and facts which changed the whole face of medicine. The physiological researches of Willis first threw light upon the structure of the brain. Woodward was the founder of mineralogy. In his edition of Willoughby's Ornithology, and in his own History of Fishes, John Ray was the first to raise zoology to the rank of a science; and the first scientific classification of animals was attempted in his Synopsis of Quadrupeds. Modern botany began with his History of Plants, and the researches of an Oxford professor, Robert Morison; while Grew divided with Malpighi the credit of founding the study of vegetable physiology. But great as some of these names undoubtedly are, they are lost in the lustre of Isaac Newton. Newton was born at Woolsthorpe in Lincolnshire, on Christmas Day, in the memorable year which saw the outbreak of the Civil War. In the year of the Restoration he entered Cambridge, where the teaching of Isaac Barrow quickened his genius for mathematics, and where the method of Descartes had superseded the older modes of study. From the close of his Cambridge career his life became a series of great physical discoveries. At twenty-three he facilitated the calculation of planetary movements by his theory of Fluxions. The optical discoveries to which he was led by his experiments with the prism, and which he partly disclosed in the lectures which he delivered as mathematical professor at Cambridge, were embodied in the theory of light which he laid before the Royal Society on[11] becoming a Fellow of it. His discovery of the law of gravitation had been made as early as 1666; but the erroneous estimate which was then generally received of the earth's diameter prevented him from disclosing it for sixteen years; and it was not till the eve of the Revolution that the Principia revealed to the world his new theory of the Universe."

Ever since the Fifteenth Century, when Copernicus revived the ancient theory of Pythagoras that the planets revolved around the sun (a theory left in an imperfect state and demonstrated later by Kepler, Galileo, Newton, and others) astronomical research has progressed steadily. It must be remembered, however, that De Revolutionibus Orbium, which met with great opposition, contained nothing regarding the laws of motion, for these had not been as yet discovered, and Saturn marked the boundaries of the Solar System. Copernicus assigned the "fixed stars" to a sphere, as in Ptolemy's heavens (see page 331).

The great Danish astronomer, Tycho Brahe, whose idea of the Solar System is represented on page 343, was his opponent. Brahe, however, a devoted student, a man of wealth, the favorite of kings and princes, and the proud possessor of the Castle of Uraniberg (City of the Heavens), an observatory equipped with fine instruments and built for him by Frederick II, King of Denmark, on the island of Hueen, and after his death the protégé of Rudolph II at Benatek, near Prague, contributed greatly to the advancement of the science by means of his discoveries, computations, solar and lunar tables, and catalogue of stars. He, like Copernicus, placed the "fixed stars" in an outer sphere. His observations on the planets were made to prove the truth of his system. This mass of observations was used instead by Johann Kepler, who had been his assistant at the Benatek Observatory, to prove Copernicus's theory. Of Kepler, the discoverer of the three famous laws, who gave a complete theory of solar eclipses, calculated the transits of Mercury and Venus, and made numerous discoveries in optics and general physics, Proctor says:

[12]

"Kepler was not merely an observer and calculator; he inquired with great diligence into the physical causes of every phenomenon, and made a near approach to the discovery of that great principle which maintains and regulates the planetary motions. He possessed some very sound and accurate notions of the nature of gravity, but unfortunately conceived it to diminish simply in

proportion to the distance, although he had demonstrated that the intensity of light is reciprocally proportional to the surface over which it is spread, or inversely as the square of the distance from the luminous body."

Great names follow in rapid succession. One of Kepler's contemporaries was Galileo Galilei, the discoverer of the "three laws of motion" and the relation of time and space in falling bodies, the first to apply the newly invented telescope to the observation of the heavens and the discoverer of four satellites of Jupiter (named by him the "Medeiran Stars" in honor of his patron). He also detected spots on the sun's disk, the phases of Venus, and irregularities on the moon's surface, and declared the Milky Way to be composed of a countless tract of separate stars.

When we remember the limited power of the telescope of the age, we can but marvel, not at how little, but how much was known regarding the starry skies.

During this period, numerous observers rendered great service to Astronomy, and other scientists were engaged in making useful drawings, charts, maps, tables, and catalogues of stars.

To this period also belongs John Bayer of Augsburg, who published a description of the constellations with maps upon which the stars were marked with the letters of the Greek Alphabet—a convenient method that was universally adopted and is still in use. Other names include Gassendi, Riccioli, Grimaldi, and Hevelius—the latter a rich citizen of Dantzig, who had a fine observatory of his own, where he worked for forty years. His drawings and descriptions of the moon, his researches on comets, which he still believed moved in parabolas, and his celestial charts engaged most of his attention.

[13]

The Dutch astronomer Huygens (born in 1629) is famous for his improvements in the telescope use of the pendulum clock and developments in the machinery of astronomical instruments. He discovered the ring of Saturn and four of his satellites. Edmund Halley, an English astronomer (born in 1656), also took a great interest in the telescope, and went to Dantzig to settle a controversy between Robert Hooke and Hevelius regarding the best glasses for use in astronomical observations; for Hevelius still worked with the ancient instruments, while Hooke believed in the lens.

Halley revived the ancient idea that comets belonged to the Solar System, and predicted that the comet of 1681 would return to its perihelion in 1759. This was the first prediction of its kind verified.

During the last quarter of the Seventeenth Century, the telescope assumes importance and two great observatories begin their work. In 1670 the Paris Observatory, of which Cassini was made director, was finished, and five years later the Greenwich Observatory, where Flamsteed was installed as royal astronomer.

Of Cassini, Lalande remarks that under him Astronomy underwent revolutions, and in France he was regarded as the "creator of the science." Cassini discovered that Saturn's ring was double and found four satellites of Jupiter.

Flamsteed's observations on planets, satellites, comets, "fixed stars," and his catalogue of 2,884 stars were valuable contributions to science; and his Historia Cœlestis is said to have "formed a new era in sidereal astronomy."

Flamsteed was succeeded by Halley, particularly famed for his investigations of comets. The next great astronomical event was the discovery of Uranus by Sir William Herschel in 1781. Sir William Herschel also discovered two more of Saturn's satellites, and began the great work of resolving the Milky Way and other clusters into swarms of suns, single stars into double and triple stars, inquiries[14] into the mysteries of the nebulæ, and in every way enlarging the general conception of the sidereal universe.

To the end of the Eighteenth and beginning of the Nineteenth Centuries belongs the brilliant French astronomer and mathematician Laplace, who published in 1799-1808 his Mécanique Céleste, in which he announced his Nebular Hypothesis (described on page 433 of Vol. II. The discoveries of the Planetoids are described on pages 396-403, and that of Neptune in 1846 on pages 430-432). The latest important additions to the Solar System are the discovery by Prof. Barnard of Jupiter's Fifth Satellite in 1892 and Saturn's Ninth by Prof. W. H. Pickering in 1904. The discovery even of a Seventh Satellite of Jupiter has just been announced from the Lick Observatory.

It would be impossible to mention the names of the astronomers whose work from the middle of the last century to its closing years has been distinguished in various fields. Space only permits brief mention of the new methods of research by means of the spectroscope and celestial photography. With the first the name of the English astronomer, William Huggins, is identified and has

yielded most important and startling information regarding the composition of heavenly bodies, and with the application of the photographic telescope these new methods have created a revolution in astronomical observation.

It may be interesting to gain a slight idea of the numbers of stars revealed by the camera by referring to Sir Robert Ball:

“If we take a position on the equator, from whence, of course, all the heavens can be completely seen in the lapse of six months, the number of stars that can be reckoned with the unaided eye will, according to Houzeau, amount to about six thousand. If we augment our unaided vision by a telescope of even small dimensions, such as three inches in diameter, the number of stars in the Northern Hemisphere alone is upward of three hundred thousand. We may assume that the Southern Hemisphere has an equally numerous star-population, so that the entire multitude visible with this optical aid is about six hundred thousand. Thus we see that[15] the use of a telescope small enough to be carried in the hands suffices to multiply the lucid stars one-hundredfold. Great telescopes no doubt soon show us that the hundreds of thousands are only the brighter members of a host of millions, and now we receive the assurance of photography that the telescopic stars are only the more conspicuous members of that vast universe. Mr. Roberts indeed declares that the multitudes of stars on the photographic plate grow with each increase of exposure to such a degree that it would almost seem as if the plate would be a wellnigh continuous mass of stars if the operations could be sufficiently protracted.”

Naturally the past years have witnessed the making of new catalogues and maps of stars, and many valuable computations of parallaxes, etc. Some of the results obtained by these new methods are described in the chapters on the Nebulæ and Swarms of Suns, The Great Nebula of Orion, and The Colored, Double, Multiple, Binary, Variable, and Temporary Stars in Vol. I. From this brief survey of the progress of Astronomy the fact will be appreciated, therefore, that all the discoveries and researches have resulted in a larger conception of the universe, and the Solar System sinks into insignificance in the vast ocean of stars and suns.

The study of the Earth’s crust and its contents divested of superstition dates from the end of the Seventeenth Century. Nicolaus Steno (1638-1687), a Dane, devoted himself to geology, and in 1669 observed successive layers of strata. He is called “the father of Palæontology.” In 1680 Leibnitz proposed the theory that the Earth was originally in a molten state. The classification of strata was begun about the middle of the Eighteenth Century. The views of James Hutton (1788), who returned to the theories advanced by Ray (a return to the views of Pythagoras), were continued by Sir Charles Lyell.

Geology and Palæontology have progressed side by side. Among the most famous investigators are Cuvier, Dawson, Marsh, Owen, Huxley, Agassiz, De Blainville, Kaup, Sir Roderick Murchison, Boyd Dawkins, Sir William Flower, R. Lydekker, and E. D. Cope.

To the review of the new developments of meteorology[16] and the science of probabilities by Sir Ralph Abercromby, on pages 784-792 of Vol. II, it is only necessary to add that the interest in meteorological research developed greatly after Torricelli’s discovery in 1643 of weight and pressure in the atmosphere led to the perfection of the barometer and the development of the thermometer and hygrometer, both in the Seventeenth Century. The theory of trade-winds George Hadley announced in the Philosophical Transactions for 1735. Dalton’s Meteorological Essays, published in 1793, and Dr. William Charles Wells’s Theory of Dew, published in 1814, attracted much attention. Regarding the inquiries into the laws of light by Snell, Newton, Descartes, Thomas Young, and Sir George Airy, the reader is referred to the chapter on The Rainbow in Vol. II, by John Tyndall, with whose researches in the latter half of the Nineteenth Century every one is more or less acquainted.

Little need be said here regarding the history of Botany, which is reviewed on pages 984-1000 of Vol. II. We may add, however, that one of the first to revive this study was Otto Brunsfels, whose Historia Plantarum Argentorati was published in two folio volumes with cuts in Strasburg in 1530. He had many followers on the Continent and in England. During the revival of learning, chairs of Botany were founded in the universities; botanic gardens were established in many places (the Jardin des Plantes was founded in 1626); and botanists began to travel to remote countries to search for unknown flora.

To the Seventeenth Century belong the names of Dr. Turner, “the father of English Botany”; Robert Morison, professor of Botany at Oxford; John Ray, Nehemiah Grew, Malpighi, Henshaw, and Robert Hooke. The two latter were among the first to employ the newly invented microscope to the study of this science. It may be mentioned in passing, that Huygens is said to have taken from Holland to England microscopes about the size of a grain of sand, and that the first microscope consisting of a combination of lenses is attributed to Jansen, a spectacle-maker of Holland.[17] Hooke, whom Herschel calls “the great contemporary and almost the rival of Newton,” gave a tremendous impetus to Microscopy, and practically laid the foundation of Histology or the Inner Morphology of Plants, due to Grew and Malpighi. Schleiden undertook to explain the mysteries of cell formation in 1838, further

investigated by Schwann, and is now known as the Schleiden-Schwann theory. Nägeli and Von Mohl continued researches on this line. To the contents of the cell Von Mohl gave the name protoplasm.

In 1849, Hofmeister began investigations into the life-histories of plants, since when the study of Vegetable Physiology has progressed side by side with Chemistry. To Darwin great subjects are due: the cross-fertilization of plants, their reproduction, and their relations to insects and their movements. It may be mentioned, however, that in 1693 Ray attempted to explain the movements of leaves, tendrils, and petals by physical and mechanical laws.

Since the middle of the Nineteenth Century, the branches of Botany that have been particularly studied are Vegetable Physiology and Pathology, Inner Morphology, and Fossil Botany—and the discoveries made have naturally had an effect upon the classification of vegetable life.

According to Agassiz:

“We must come down to the last century, to Linnæus, before we find the history taken up where Aristotle had left it, and some of his suggestions carried out with new freshness and vigor. Aristotle had already distinguished between genera and species; Linnæus took hold of this idea, and gave special names to other groups, of different weight and value. Besides species and genera, he gives us orders and classes—considering classes the most comprehensive, then orders, then genera, then species. He did not, however, represent these groups as distinguished by their nature, but only by their range; they were still to him, as genera and species had been to Aristotle, only larger or smaller groups, not founded upon and limited by different categories of structure. He divided the animal kingdom into six classes: Mammalia, Birds, Reptiles, Fishes, Insects, and Worms.”

[18]

Linnæus’s classification was, therefore, the first attempt to group animals; but until Cuvier there was no great principle of classification. In 1707 Buffon succeeded in making Zoology, which had been regarded as a most uninteresting study, popular and respected. He also had the idea of collecting all the known facts of scientific investigation and arranging them systematically. Buffon was ridiculed as a scientist by his contemporaries, Hevelius, Diderot, D’Alembert, and Condillac, who opposed his explanations of natural phenomena. Buffon’s Histoire Naturelle Générale et Particulière is his most important work. A complete edition in thirty-six volumes appeared in Paris in 1749-1788. Although it is said to “have made an epoch in the study of the natural sciences” in Buffon’s day, it now possesses little scientific value.

Cuvier’s classification has never been overthrown. His original investigations in various departments of science, and particularly that of fossil vertebrate animals, opened up new fields of study. His talents with both pen and pencil contributed largely to making that branch of science popular.

Lamarck, Cuvier’s contemporary, divided the animal kingdom into Vertebrates and Invertebrates. Lamarck, like Geoffroy Saint-Hilaire, was a believer in the theory of evolution, which was opposed by Cuvier.

Lamarck turned from the study of Meteorology to that of Botany, and later again to that of Zoology. In 1793 he became professor of the natural history of the lower classes of animals in the Jardin des Plantes. His theories have greatly influenced modern science, particularly that of the “Variation of Species,” which was set forth in his Philosophie Zoologique (two vols., Paris, 1809) and other works. Lamarck’s Histoire des Animaux sans Vertèbres (seven vols., Paris, 1815-22) is his greatest work.

Karl Ernst von Baer, the Russian naturalist, a pupil of Döllinger in Würzburg, devoted himself chiefly to the study of embryology and made valuable discoveries.

[19]

Passing by many illustrious names, we come to that of Sir Richard Owen, of whom it has been said that “from the sponge to man, he has thrown light over every subject he has touched.” His work in the Hunter Museum, his descriptions and restorations of extinct birds and animals, and his original works on every branch of animal life, form an enormous contribution to the progress of science. He promulgated the advanced views of John Hunter, the great physiologist and surgeon, of whose famous museum of more than ten thousand specimens, illustrative of anatomy and natural history, he became curator.

Three names shine with especial lustre upon the Nineteenth Century—Darwin, Huxley, and Spencer. The theory of evolution first appeared in De Maillet’s work, Telliamed, published in 1758, but written in 1735. More than thirty writers before Darwin treated this

theory, among whom were Erasmus Darwin, Goethe, Lamarck, and Geoffroy Saint-Hilaire. Largely owing to the opposition of Cuvier, it never succeeded until it was revived by Charles Darwin, who, after twenty-one years of work, published his results in 1858 in the Journal of the Linnæan Society, followed in the next year by The Origin of Species by Means of Natural Selection (see pages 1482-1512 of Vol. IV).

“The lifeless earth,” says Sir Robert Ball, “is the canvas on which has been drawn the noblest picture that modern science has produced. It is Darwin who has drawn this picture. He has shown that the evolution of the lifeless earth from the nebula is but the prelude to an organic evolution of still greater interest and complexity. He has taken up the history of the earth at the point where the astronomer left it, and he has made discoveries which have influenced thought and opinion more than any other discoveries that have been made for centuries.”

The neglected department of Marine Zoology the Nineteenth Century has made particularly its mission to investigate, but space only permits mention of four names: Edward Forbes, Lord Kelvin (Sir Wyville Thomson), Ernst Heinrich Haeckel, and the Prince of Monaco.

[20]

The first, whom Lord Kelvin considers “the most accomplished and original naturalist of his time,” was a pupil of Geoffroy Saint-Hilaire, Jussieu, and De Blainville. He is regarded as the originator of the use of the dredge for collecting specimens and the first who undertook the systematic study of Marine Zoology with reference to the distribution of fauna. In 1859 his Natural History of the European Seas appeared after his death.

One of the most important investigators in this line is Prof. Haeckel, famous for his studies of the lower class of marine animals. He is also distinguished for his researches in other branches of Zoology and Palæontology, and was one of the first followers of Darwin in Germany.

Entomology has also made enormous progress during the Nineteenth Century. At the end of the Seventeenth Century, Ray estimated the number of insects throughout the world at 10,000 species! The great entomologists of the Eighteenth Century include Linnæus, De Geer, and Fabricius. Next follow Latreille, Kirby and Spence, and a host of distinguished scientists in Europe and the United States, of whom Sir John Lubbock (Lord Avebury) heads the list. A comparatively new line of investigation is that of the Chalcididæ (see Fairy Flies, pages 1449-1458, in Vol. IV).

THE

STORY OF THE UNIVERSE THE HEAVENS.—Amédée Guillemin

What are the heavens? Where the shores of that limitless ocean; where the bottom of that unfathomable abyss?

What are those brilliant points—those innumerable stars, which, never dim, shine out unceasingly from the dark profound? Are they sown broadcast—orderless, with no other bond save that which perspective lends to them? Or, if not immovable, as we have so long imagined, if not golden nails fixed to a crystal vault, whither are they bound? And, finally, what are the parts assigned to the sun, our earth, and all the earths attendant on the glorious orb of day in this tremendous concert of celestial spheres—this sublime harmony of the universe?

These are magnificent problems of which the most fertile imagination would have in vain attempted the solution, if, for the greater glory of the human mind, astronomy—first born of the sciences—had not at length come to our aid.

How wonderful is the power of man! Chained down to the surface of the earth, an intelligent atom on a grain of sand lost in the immensity of a space, he[26] invents instruments which multiply a thousand-fold his vision, he sounds the depths of the ether, gauges the visible universe, and counts the myriads of stars which people it; next, studying their most complicated movements, he measures exactly their dimensions and the distances of the nearest of them from the earth, and next deduces their masses; then, discovering in the seeming disorder of the stellar groupings real bonds of union, he at last evolves order from apparent confusion.

Nor is this all. Rising by a supreme flight of thought to the most abstract speculations, he discovers the laws which regulate all celestial movements, and defines the nature of the universal force which sustains the worlds.

Such are the fruits of the unceasing labors of twenty generations of astronomers. Such the result of the genius and of the patient perseverance of men who have devoted themselves for two thousand years to the study of the phenomena of the heavens. The Chaldean shepherds were, they say, the first astronomers. We can well believe it. Dwelling in the midst of vast plains, where the mildness of the seasons permitted them to pass the night in the open air, where the clear sky unfolded before them perpetually the most glorious scenes, they ought to have been, and they were, contemplative astronomers. And all of us would be what they were did not the rigor of our climate and our variable atmosphere so often prevent us observing the heavens; and did not, moreover, the turmoil and cares of civilized life deprive us of the necessary leisure.

[27]

Nothing is more fitted to elevate the mind toward the infinite than the pensive contemplation of the starry vault in the silent calm of night. A thousand fires sparkle in all parts of the sombre azure of the sky. Varied in color and brilliancy, some shine with a vivid light, perpetually changing and twinkling; others, again, with a more constant one—more tranquil and soft; while very many only send us their rays intermittently, as if they could scarce pierce the profundity of space.

To enjoy this spectacle in all its magnificence, a night must be chosen when the atmosphere is perfectly pure and transparent—one neither illuminated by the moon, nor by the glimmer of twilight or of dawn. The heavens then resemble an immense sea, the broad expanse of which glitters with gold dust or diamonds.

In presence of such splendor, the senses, mind and imagination are alike inthralled. The impression gathered is an emotion at once profound and religious, an indefinable mixture of admiration, and of calm and tender melancholy. It seems as if these distant worlds, in shining earthward, put themselves in close communication with our thoughts.

At a first glance at the starry firmament the stars seem pretty regularly distributed; nevertheless, look at that whitish, undecided, vapory glimmer which girdles the heavens as with a belt. It is the Milky Way.[1] As we approach the borders of this star-cloud in our inspection, the stars appear more and more[28] crowded together, and most of them so small that the eye can scarcely distinguish them. The accumulation of stars in the direction of the Milky Way is more especially visible when we examine the heavens with the aid of a powerful telescope.

The Milky Way itself is nothing more than an immensely extended zone of stars, that is, of suns, since each star, from the most brilliant to the faintest, is a sun.

Here, then, is an immense group, a gigantic assemblage of worlds, which seems to embrace all the universe, if it be true that the greater number of the scattered stars situated out of the Milky Way nevertheless form part of it. In reality, this multitude of millions of suns is divided into numerous and distinct groups, and those into others still more restricted in number, each composed of two or three suns.

What breadth of space does each of these groups occupy? What is the measure of the space which holds them all? The most powerful imagination in vain attempts to answer these questions intelligibly; here numbers fail us.

Let us add—a fact well proved, and one which will seem strange to many—

Our sun himself is a star of the Milky Way.

In examining attentively every part of the starry vault, a keen eye perceives here and there whitish spots resembling little clouds. One would say they were so many patches detached from the Milky Way, from which, however, they are often very distinct and very distant. The telescope discovers by thousands[29] those cloud-patches, these—to give them their astronomical name—Nebulæ.

It was formerly imagined that each of these star-clouds was nothing more than an accumulation of stars, very close together, and very numerous—so many Milky Ways lying outside our own, and for the most part so distant that the most powerful instruments were able only to distinguish a confused glimmering. One of the most important observations of modern times, however, has shown that many of these nebulæ, including the most glorious one in our northern hemisphere—that in the sword-handle of Orion—are but masses of glowing gases.

Others, again, of these cloud-like masses—cloud-like by reason of their distance—show us, faintly shining on a background of apparent nebulæ, brilliant stars, larger no doubt, or more brilliant, than their fellows, and some of these objects called "Star-Clusters," which are nearest to us, are among the most glorious objects revealed to us by our telescopes.

Let us attempt now to conceive what fearful distances separate these archipelagoes of worlds from our own!

Unfathomable abysses whose unspeakable depths the most powerful telescopes increase indefinitely! Profound, endless, bottomless, but lighted up by millions of suns!

Such appears to us the universe from the natural observatory where we are placed. But to obtain a more complete idea of its constitution, of the infinite variety of its members, we must descend from those regions, where the sight and mind are lost, to a[30] group, nearer to us, and therefore more accessible to the investigations of man—to that group, or system, of which the earth forms part.

Of this the sun is the centre.

Round this focus of light and heat, but at various distances, revolve more than a hundred secondary bodies—Planets, some of which are accompanied by smaller ones—Satellites. Not self-luminous, they would be invisible to us, if the light, which they receive from the sun, were not reflected toward the earth, making them also appear as luminous points spread over the celestial vault like so many stars. Such would be the appearance of the earth seen in space, at a distance sufficiently great.

A common character distinguishes all the celestial bodies that form part of this group—the Solar System—from the multitude of other stars. For while the suns, composing what is called the Sidereal Universe, are situated at distances seemingly infinite, the bodies composing the group of which we speak are relatively much nearer the earth, are, in fact, our neighbors.

What results from this double fact? Two very simple consequences, easily understood.

The first is, that the stars do not undergo any sensible change of position in the starry vault. Their distance is such that they appear actually at rest in the depths of space; hence the term Fixed Stars—now abandoned, because a minute and elaborate study of their relative positions has established the fact that the stars really do move in the remote regions of the heavens. The apparent immobility of[31] which we have spoken, and which is one of their characteristics, is evidenced by the uniformity of appearance preserved for centuries by the artificial groups of stars, to which the name of Constellations has been given.

Now, it is otherwise with the bodies that revolve round our sun: they are near enough to the earth to allow of their displacements in space being perceived in short intervals of time. Traveling, by virtue of their proper motions along the starry vault, distances which appear greater as their own distance from us is less, these bodies received at the outset the name they have since retained—Planets, or Wandering Stars.

It is thus that, when we stand in the middle of an extensive plain, we judge distant objects—those that border the horizon—to be immovable; while we instantly perceive the slightest change of place in the near ones. It is true that when we ourselves move, the real movements become complicated with the apparent movements, but the former must be distinguished, if we wish to have an exact idea of the actual course traveled. This complication of the apparent movements of the planets—a necessary consequence

of the movement of the earth—is one of the most striking testimonials to the reality of the latter; but it must also be added, that this was precisely the stone of stumbling of ancient astronomy until the time—and that not long ago—when the real movements were made known. Movements of rotation, movements of revolution, around the common centre, the duration of these movements, distances,[32] forms and dimensions, distribution of light and heat, all change in passing from one planet to another. And yet, marvelous thing, the same laws govern, all in such a way that the unity of plan is not less marked than the astonishing variety of the phenomena.

One circumstance common to all the bodies of the solar system forcibly strikes the imagination. It is, that these enormous masses—these globes, many of which are much heavier than the earth, and lastly, the earth itself—are not only suspended in space, but move through the ether with velocities truly stupendous.

Imagine yourself a spectator, standing immovable in space. A luminous body appears in the distance, little by little you see it approach and increase in size; its immense circumference, which exceeds a hundred thousand leagues, is in rapid rotation, which makes each point on its periphery travel through nine miles a second. The globe itself passes before you, carried through space with a velocity twenty-four times greater than that of a cannon-ball. In such a way Jupiter would appear to you traveling in its orbit. This headlong course would banish it forever to the most remote regions of the visible universe, if it were not subdued and held by the powerful attraction of a globe a thousand times larger than its own—by the sun himself. Not only does astronomy show, by undeniable proofs, the reality of these marvelous movements—not only has she arrived at the knowledge of their invariable constancy, at least during thousands of centuries; but she[33] has found in their very rapidity the cause of the stability of all the celestial bodies.

If there is difficulty in imagining such masses freely circulating in the ether, how much more are we impressed when we consider that these rapid movements are not confined to the planets; and when we look upon the sun with all his retinue as moving in an orbit yet unknown, himself attracted no doubt by a more powerful sun, or by a group of suns! All the stars which by reason of their infinite distances appear immovable, move in different directions; and we shall see later, that if these movements are performed with extreme slowness, the slowness is apparent only. In reality, these are the most rapid celestial movements that we know of.

Thousands of centuries will be necessary before these immense sidereal voyages are accomplished. Their vast periods are to the length of our year what the dimensions of the earth are to the distances of the stars; and, according to the happy expression of Humboldt, they make of the universe an eternal timekeeper. Thus, in the contemplation of celestial phenomena, the idea of infinite duration impresses itself on the mind with the same irresistible power as the idea of the infinity of space. FOOTNOTES:

[1] Via Lactea. It is also called the Galaxy, from the Greek word for the same thing. SPACE.—Richard A. Proctor

Although astronomy tells us in the clearest words of the vast depths of space which surround our earth on all sides, we are not thereby enabled to realize their enormous extension. It is not[34] merely that the unknown depths beyond the range of our most powerful telescopes are inconceivable, but that the parts of space which we can examine are on too large a scale for us to conceive their real dimensions. It is hardly going too far to say that our powers of actual conception are limited to the extent of space over which the eye seems to range in the daytime. Of course, in the daytime, at least in clear weather, there is one direction in which the eyesight ranges over a distance of many millions of miles—namely, where we see the sun. But the sense of sight is not cognizant of that enormous distance, and simply presents the sun to us as a bright disk in the sky, or perhaps rather nearer to us than the sky. Even the distance of the sky itself is underestimated. A portion of the light we receive from the sky on a clear day comes from parts of the atmosphere distant more than thirty or forty miles from us; but the eye does not recognize the fact. The blue sky seems a little further off than the clouds, but not much; the light clouds of summer seem a little, but not much, further off than the heavier clouds of a winter sky; a cloud-covered winter sky seems a little further off than heavy rain-clouds. The actual varieties of distance among clouds of various kinds are not much more clearly discerned than the actual varieties of distance among the heavenly bodies. The estimate formed of the distance of a cloud-covered sky overhead probably amounts to little more than a mile, and it is very doubtful whether the mind presents the remotest depths of a blue sky overhead at more than two miles. Toward the horizon the distance[35] seems greater, and probably on a cloudy day the sky near the horizon is unconsciously regarded as at a distance of about five miles, while blue sky near the horizon may be regarded as lying at a distance of six or seven miles, the arch of a blue sky seeming to be far more deeply curved than that of a cloud-covered sky.

It is to distances such as these that the mind unconsciously refers the celestial bodies. We know that the moon is about 2,000 miles in diameter, but the mind refuses to present her to us as other than a round disk much smaller than those other objects in sight

which occupy a much larger portion of the field of vision. The sun can not be conceived to exceed the moon enormously in size, seeing that he appears no larger; and all the multitude of stars are judged by the sight to be mere bright points of light in reality as they appear to be.

How, then, can we hope to appreciate the vastness of space whereof astronomy tells us? To the student of science attempting to conceive the immensities of whose existence he is assured, the same lesson might be taught in parable which the child of St. Augustine's vision taught the Numidian theologian. As reasonably might an infant hope to pour the waters of ocean into a hollow, scooped with his tiny fingers in the sand, as man to picture in his narrow mind the length and breadth and depth of the abysses of space in which our earth is lost.

Yet, as a picture of a great mansion may be so drawn on a small scrap of paper as to convey just ideas of its proportions, so may the great truths which[36] astronomy has taught us about the depths of space be so presented that just conceptions may be formed of the proportions of at least those parts of the universe which lie within the range of scientific vision, though it would be hopeless to attempt to conceive their real dimensions.

When we learn that a globe as large as our earth, suspended beside the moon, would seem to have a diameter exceeding hers nearly four times, so that the globe would cover a space in the heavens about thirteen times as large as the moon covers, we form a just conception of the size of the moon as compared with the earth, though the mind can not conceive such a body as the moon or the earth really is. When, in turn, we are told that if a globe as large as the earth, but glowing as brightly as the sun, were set beside the sun, it would look a mere point of light, we not only learn to picture rightly to ourselves how largely the sun exceeds the earth, but also how enormous must be the real distance of the sun.

Another step leads us to a standpoint whence we can form a correct estimate of the vast distance of the fixed stars; for we can learn that so enormous is the distance of even the nearest fixed star, that the tremendous space separating the earth from that star sinks in turn into the merest point, insomuch that if a globe as bright as the sun had the earth's orbit as a close-fitting girdle, then this glorious orb (with a diameter of some 184,000,000 of miles) would look very much smaller than such a globe as our earth would look at the sun's distance—would, in fact, occupy but about one-fortieth[37] part of the space in the sky which she, though she would then look a mere point, would occupy if viewed from that distance.

But there is a way of viewing the immensities of space which, though not aiding us indeed to conceive them, enables the mind to picture their proportions better than any other. The dimensions of the earth's path around the sun sink into insignificance beside those of the outermost planets; but these in their turn dwindle into nothingness beside those of some among the comets. From the path of these comets, if only sentient and reasoning beings could trace out in a comet's company those mighty orbits, and could have for the duration of their existence not the brief span of time which measures the longest human life, but many circuits of their comet home around the same ruling orb (as we live during many circuits of our globe around the sun), the dimensions of the star-depths, which even to scientific insight are all but immeasurable, would be directly discernible. Not only would the proportions of that mighty system be perceived, whose fruits and blossoms are suns and worlds, but even the gradually changing arrangement of its parts could be discerned.

Some comets, indeed, do not travel around the sun, but flit from sun to sun on journeys lasting millions of years, paying each sun but a single visit. A being inhabiting such a comet, and having these interstellar journeys as the years of his existence, so that he could live through many of them, would have a wonderful insight into the economy of the stellar system. If his powers of conception as far exceeded[38] ours as the range of his travels and the duration of his existence, he would be able to recognize the proportions of a large part of the stellar universe as clearly as we recognize the proportions of the solar system.

But leaving these wonderful wanderers, whose journeys are as far beyond our powers of conception as the immensity of the regions of star-strewn space, we may find, among the comets belonging to the sun's domain, bodies whose range of travel would give their inhabitants far clearer views of the architecture of the heavens than even the profoundest terrestrial astronomer can possibly obtain.

Such a comet as Halley's, for instance, though one of comparatively limited range in space, yet travels so far from the sun that, from the extreme part of its path, it sees the stars displaced nearly twenty times as much (owing to its own change of position) as they are from the earth on opposite sides of her comparatively narrow orbit. And the length of this comet's year, if it indicated the lives of all creatures traveling along with it, would suggest a power of patiently watching the progress of changes lasting not a few of our years only, but for centuries. Seventy-five or seventy-six years elapse between each return of this comet to the sun's

neighborhood, and one who should have lived during sixty or seventy circuits of this body around its mighty orbit would have been able to watch the rush of stars, with their velocities of many miles per second, until visible displacements had taken place in their positions.

This, however, is as nothing compared with the[39] mighty range in space and the enormous period of the orbit of the great comet of the year 1811. This comet is, on the whole, the most remarkable ever known. It was visible for nearly seventeen months, and though it did not approach the sun within 100,000,000 miles, and was therefore not subject to that violence of action which has caused enormous tails to be thrown out from comets which have come within a few million miles of him, or even within less than a quarter of his own diameter, it flourished forth a tail 120,000,000 of miles in length. Its orbit has, according to the calculations of the astronomer Argelander, a space exceeding the earth's distance from the sun 211 times, and thus surpassing even the mighty distance of Neptune fully seven times. It occupies in circuiting this mighty path no less than 3,065 of our years (with a possible error either way of about forty-three years). So that, according to Bible chronology, this comet's last appearance probably occurred during the rule of the Judge Tola, son of Puah, son of Dodo, over the children of Israel, though it may have occurred during the rule of his predecessor Abimelech, or during that of his successor Jair.[2] During one-half of the enormous interval[40] between that time and 1811 the comet was rushing outward into space, reaching the remotest part of its path somewhere about the year 278 (A. D.), and from that time to 1811 it was on its return journey. It is strange to think, however, that though the remotest part of its path lay 211 times further from the sun than the earth's orbit, yet even this mighty path, requiring more than 3,000 years for a single circuit, can not be said to have carried the comet into the star-depths. If the earth were to shift its position by the some enormous amount, the nearest fixed star would have its apparent position changed only by about an eighth part of the apparent diameter of the sun or moon, or by about one-quarter of the distance separating the middle star of the Bear's tail from its close companion.

But this fact of itself is most strikingly suggestive of the vast distance of the stars. For consider what it means. Imagine the middle star of the Bear's tail to be the really nearest of all the stars instead of lying probably twenty or thirty times further away. Conceive a comet belonging to that sun after making its nearest approach to it to travel away upon an orbit requiring 3,000 years for each circuit. Then (supposing that star equal to our sun in mass) the comet, though rushing away from its sun with inconceivable velocity during 1,500 years, would, at the end of that vast period, seem to be no further away than one-fourth of the distance separating the sun from its near companion. Look at the middle star of the Bear's tail on any clear night, and on its small satellite, remembering this fact, and the awful immensity[41] of the star-depths are strongly impressed upon the mind. But the observer must not fail to remember that the star really is many times more remote than we have here for a moment supposed, and that such a comet's range of travel would be proportionately reduced. Moreover, many among the stars are doubtless hundreds, even thousands, of times still further away.

Let us turn lastly to the amazing comet of the year 1744. We find that though it had the longest period of any which has ever been assigned to a comet as the result of actual mathematical calculation, yet its range in space would scarcely suffice to change the position of the stars in such sort that the aspect of the familiar constellations would be materially altered. Euler, the eminent mathematician, calculated for this comet a period of 122,683 years, which would correspond, I find, to a distance of recession equal to 2,469 times the distance of the earth from the sun, or about eighty times the distance of Neptune. Yet this is but little more than twelve times the greatest distance of the comet of 1811. Probably the actual range of such an orbit from the middle star of the Bear's tail would be equal in appearance to the range described above on the supposition that the star is no further from us than the nearest known star (Alpha Centauri). That is, such a comet, if it could be seen and watched during a period of about 122,000 years, would seem to recede from the star to a distance equal to about one-fourth the space separating it from its close companion, and then to return to the point of nearest approach to its ruling sun.

[42]

Such are the immensities of star-strewn space! The journey of a comet receding from the sun with inconceivable velocity during hundreds of thousands of years carries it but so small a distance from him compared with the distance of the nearest star as scarcely to change the appearance of the celestial landscape; and yet the distances separating the sun from the nearest of his fellow suns are but as hairbreadths to leagues when compared with the proportions of the scheme of suns to which he belongs. These distances, though so mighty that by comparison with them the inconceivable dimensions of our own earth sink into utter nothingness, do not bring us even to the threshold of the outermost court of that region of space to which the scrutiny of our telescopes extends. Yet the whole of that region is but an atom in the infinity of space. FOOTNOTES:

[2] It might be suggested that the appearance of this blazing comet among the stars drove the more superstitious of the Israelites at that time to the worship of star-gods, as we read how, during the Judgeship of Jair, they “served Baalim and Ashtaroth, and the gods of Syria and the gods of Moab, and the gods of the Philistines, and forsook the Lord and served not Him.” To a people like the Jews, who seem to have been in continual danger of returning to the Sabaistic worship of their Chaldean ancestors, the appearance of a blazing comet may have been a frequent occasion of backsliding. EXTENT OF THE SIDEREAL HEAVENS.—Sir Robert S. Ball

Of all the discoveries that have ever been made in science there are two which especially baffle our powers of comprehension. They lie at the opposite extremes of nature. One relates to objects which are infinitely small, the other relates to objects which are almost infinitely great. The microscope teaches us that there are animals so minute that if a thousand of them were ranged abreast they would easily swim without being thrown out of line through the eye of the finest cambric needle. Each of those minute creatures is a highly organized number of particles,[43] capable of moving about, of finding and devouring its food, and of behaving in all other respects as becomes an animal as distinguished from an unorganized piece of matter. The mind is capable of realizing the structure of these little creatures, and of fully appreciating their marvelous adaptation to the life they are destined to lead. If these animals excite our astonishment by reason of their extreme minuteness, there is an appeal made to conceptions of an entirely different character when we learn the lessons which the telescope teaches. As the microscope reveals the excessively minute, so does the telescope disclose the sublimely great. In each case myriads of objects are submitted to our astonished view, but while the microscope brings before us creatures of which countless millions could swim about freely in a thimbleful of water, the telescope conducts our vision to uncounted legions of stars, many of them millions of times larger than the earth.

The grandest truth in the whole of nature is conveyed in that first lesson in astronomy which answers the question: What are the stars? This is a question that a child will ask, and I have heard of a child’s pretty idea that the stars were little holes in the sky to let the glory of heaven shine through. The philosopher will replace this explanation by another hardly less poetical, which will enable us to form some more adequate notion of the real magnificence of the universe. Each star that we see is, it is true, only a glittering little point of light, but that is merely because we are a long way from it. An electric light which will dazzle your eye when quite[44] close will be reduced to an agreeable illumination if it is at a little distance, will become a faint light a mile away, and at no great distance will become altogether invisible. We must remember that out in space there is plenty of room—there are no bounds; and therefore when we see light glistening in the far distant depths we can not at once conclude that the light is a faint one because it appears to us to be faint. It may be that the light is only faint because it comes from such a tremendous distance. In fact, the brightest light conceivable could be reduced to the insignificance of a small star if only it were removed sufficiently far.

The most intense light we know of comes, of course, from the light which rules by day, from our sun himself. The sun pours his unrivaled beams around us in all directions with prodigal abundance, notwithstanding his enormous distance of ninety-three millions of miles. Let me describe an experiment with respect to our sun, an experiment, it is needless to say, which could never be performed, but the results to which it leads us are none the less certain. Astronomers have demonstrated them in many other ways.

Suppose that the sun were gradually to be moved away further and further into space; suppose that by this time to-morrow the great luminary should be twice as far as it is now, and the next day should be three times as far, and the day after that four times, and so on until in a year’s time we should find that the sun was 365 times the distance from us that it is at present. Let us now trace the changes[45] which we should see in the brilliancy of our orb of day. When he had reached double his distance from us, we should find that the light had decreased to a quarter of its present amount, and the heat which we derived from his beams would have decreased in the same proportion. In ten days we should find that the light had become so feeble as to be only one-hundredth part of that which we enjoy now. The apparent size of the sun would also be steadily decreasing, for as the distance of a body increases its apparent dimensions diminish. Sometimes the diminution of apparent size with distance is well illustrated on a clock tower. You would hardly believe that the hands and face of a clock like that at Westminster were so large until you happen to see a man cleaning or repairing it, when he appears a mere pigmy in comparison with the mighty dial which points out the hours. In a similar way with every increase of distance, the apparent size of the sun would decline, and in the lapse of a year the sunlight would be reduced to a feeble twilight. The sun itself would remain visible for many years, even if it were steadily moving away, though its lustre would continually decline, and its size would continually diminish, until at last it would have shrunk to the insignificance of a small point of light, still visible as a glittering object, but too minute to enable any definite form to be perceived.

Further still, the sun might recede until it passed beyond the reach of vision of the unaided eye; the telescope would, however, be able to pursue the retreating luminary until at last it sank into the[46] depths of space beyond the reach of any instrument whatever.

This little argument will prepare us for an explanation of the stars. They merely appear to us to be points of light of varying degrees of brightness, but we have seen that our own sun might be reduced in lustre to that of the very dimmest of the stars if only it were removed sufficiently far. If, therefore, the stars are at a great enough distance from our system, it may indeed be that they also are suns, possibly equaling, or possibly even surpassing, our own sun in magnificence.

Here is indeed an imposing suggestion. Can it be that the host of stars which adorn our midnight sky are actually suns themselves of an importance comparable with that of our own? This is a great thought, and we desire to test it by every means in our power. You will see from the reasoning I have given that the whole question turns simply on one point, and that is: How far off are the stars?

The tiniest point of light that is just seen as a glimmer in the mightiest of telescopes may be indeed a sun as great, or indeed a million times greater, than our sun, if only that star be sufficiently far off. To find the distance of a star is a problem which taxes the utmost powers of the painstaking astronomer; every refinement of skill in making his measurements and of care in the calculation of his observations have to be lavished on the operation. Alas! it but too often happens that the astronomer's labors prove to be futile. The surveying navigator often has to mark on his chart that no bottom could be[47] found in the depths of the sea. His appliances would not work, or work reliably, in those ocean abysses; so, too, the astronomer, when he tries to sound the depths of space to the distances of the stars, has also to mark, generally speaking, "No bottom here," as the result of most of his investigations. When this is the case we know for certain that the star on which his calculations have been made must be a gorgeous sun, because we are assured of the greatness of its distance, even though we have not been able to find out what that distance was. There are, however, some few places through the sky where the astronomer's sounding line can, so to speak, touch bottom; there are a few stars of which we do know the distance, and the result is not a little significant. Were our sun to be withdrawn from us to a distance so great as that of the very nearest of the stars, our magnificent ruler and benefactor would certainly have lost all his splendor; he would, in fact, have shrunk to the similitude of a little star not nearly so bright as many of those which we see over our heads every night. Imagine the sun's light subdivided into two hundred thousand parts, each of which would give us only a feeble illumination, and then imagine that each of these parts was again divided into two hundred thousand parts more, and it is one of these last fragments that would represent the miserable lustre which the sun would then display.

From these considerations we can enunciate the magnificent truth which astronomy discloses to us. I do not think that in the whole range of nature there is any thought so magnificent or so imposing as that[48] which teaches us to regard every star of every constellation as a sun. We can not indeed assert that they are all so great as our sun, but we can affirm with certainty that many of them are far greater and far more splendid. Considering that our sun presides over a system of worlds of which the earth is one, that it gives light and heat to those worlds, and guides them in their movements, it would greatly enlarge our conceptions of the universe if we were assured that there was even one more sun as large and as splendidly attended as is our own. But now we find that not only is there one additional sun, but that they teem in uncounted thousands through space. Look, for example, on the next fine night at the Great Bear, the best known of all our northern constellations, and there you see seven stars forming the well-known feature. Figure in your mind's eye each one of those stars in the likeness of a majestic sun, as big, warm, and bright as our sun, and look at other parts of the sky and repeat the process with the other constellations, and your conception of the magnificence of the starry system will begin to assume proper proportions. But this is only the first step, you must next look at the smaller stars, and reflect that they, too, are also suns, only much further off as a general rule than the brighter stars, though this is by no means invariably the case. Thus your estimate of the number of suns in the universe will rise to thousands, but you will not stop there, you will get a telescope to help you, and, to your extreme delight and wonder, you will find that there are hosts of stars—too faint to be visible to the[49] eye, but which the telescope will immediately disclose. You will get a more powerful instrument, and then you will perceive that the stars are to be numbered by tens of thousands, and even by millions, and with every fresh accession of power in your telescope fresh troops and myriads of suns are revealed. Suns in clusters, suns strewn thickly here and sparsely there, so as to give us the notion that the only limit to the number we can see is the power of the telescopes we are using. Attempts at actual numeration are futile, for who can tell the number of the stars?

We can, however, form an estimate, and by taking samples, so to speak, of the sky here and other samples there, we have been enabled to learn the overwhelming fact that our universe does contain at the very least one hundred millions of suns.

In discussing the extent of the visible universe, it must always be borne in mind that the further a source of light is from us the fainter is the illumination which we receive from it. Suppose that a star which just lies on the limits of naked-eye visibility were somehow to be transported to a distance which is twice as great, then the lustre of that star would be diminished to one-fourth of its original amount. It would, therefore, be of course invisible to the unaided eye, but could still be easily perceived by a telescope.

Indeed, the very word telescope means an instrument for looking at objects a long way off, and the effect of the telescope is to reduce the apparent distance of the object.

The bulk of a grain of sand as compared with the[50] bulk of a football may illustrate the space accessible to our eyes when compared with the space accessible to one of the great telescopes. The larger of these spaces has a thousand times the diameter of the others; therefore, the relative quantities of these spaces are to be obtained by multiplying 1,000 by 1,000 and by 1,000 again. Thus we finally learn that the amplitude of our vision is augmented to one thousand million times its original extent by the use of our greatest telescopes. It need, therefore, be no matter for surprise that the number of stars visible through our great telescopes or recorded on the sensitive films of photographic plates should number scores of millions. In fact, it would sometimes seem surprising that the number of telescopic stars is not even greater than it actually appears to be. If we are able to explore one thousand million times as much space, we might expect that the number of objects disclosed would be also increased about a thousand million-fold, but this is certainly not the case. The truth seems to be that our sun is but one star of a mighty cluster of stars; we happen to lie near the middle of the cluster, and the rest of the stars belonging to it form what we know as the Milky Way. There are, of course, other clusters scattered through the heavens, some of them, perhaps, as great as that body of stars which forms the Milky Way. Owing to our residence in this cluster we see the neighboring suns in multitudes, and thus we receive the impression that the solar system lies in an exceptionally rich part of the universe in as far as the distribution of stars is concerned.

[51]

On the outskirts of the universe lie those faintest and dimmest of objects which we can just perceive through our greatest telescopes. We know that many of the stars around us would still remain visible in great instruments, even though they were removed a thousand times as far off. Among the myriads of faint stars which we see from our observatories, there may be many, indeed there must be many, which are fully a thousand times as distant as the bright stars which twinkle in our comparative neighborhood. We thus obtain some conception of the stupendous distance at which the outskirts of the universe are situated.

There are different ways of illustrating this point, but I think the simplest, as well as the most striking, is that which is founded on the velocity of light. It is a remarkable fact that the beautiful star known as Vega[3] has a distance from us so tremendous that its light must have taken somewhere about eighteen years to travel hither from thence. Notwithstanding that the light dashes along with such inconceivable speed that it will cover 185,000 miles in every second, notwithstanding that a journey at this pace will complete the entire circuit of this globe seven or eight times between two successive ticks of the clock, the light will, nevertheless, take eighteen years to reach our eye from the time it leaves Vega. We do not, therefore, see the star as it is at present; we see it as it was eighteen years ago. For the light which this evening enters our eyes has been all that[52] time on its journey. Indeed, if Vega were actually to be blotted out from existence it would still continue to shine out as vividly as ever for eighteen years before all the light on its way had reached us.

We have been led to the belief that among the more distant stars in the universe there must be many which are fully a thousand times as far from us as is Vega, hence we arrive at the startling conception that the light they emit has been on its journey for 18,000 years before it reached us. When we look at those lights to-night we are actually viewing them as they were 18,000 years ago. In fact, those stars might have totally vanished 17,000 years ago, though we and our descendants may still see them glittering for yet another thousand years.

We shall realize a little more fully what this reasoning involves if we suppose that astronomers dwelt on such a star, and that they had eyes and telescopes sufficiently keen not only to discern our little earth, but even to scrutinize its surface with attention. Let us suppose that the stellar astronomers looked at England: do you think they would see a network of railways joining mighty and populous cities, furnished with immense manufactories and with countless institutions? Such would be the England of to-day. But from the distance at which these astronomers are situated light takes 18,000 years for its journey, and, therefore, what they would see would be England as it was 18,000 years ago. To them England would even now appear as a country mainly covered with forests inhabited by bears and wolves, and totally void of any trace of civilization. This illustration[53] will, at all events, serve to convey some conception of the distance at which the outskirts of our visible universe are plunged in the depths of space.
FOOTNOTES:

[3] Vega is the brightest star in the Lyre and is nearly always at night directly overhead in our latitude.—E. S. THE STARS.—Amédée Guillemin

No sight is at once so awe-inspiring and so grand as that of the heavens on a beautiful night. If care be taken to choose as a standpoint for observation an open place, such as a plain or the summit of a hill on land, or, again, the open sea, and if the atmosphere, somewhat charged with dew, possesses all its transparency and purity, we shall see thousands of luminous points twinkling in all directions, accomplishing slowly and together their silent march. The contrast of the obscurity which reigns on the surface of the earth with the brightness of that resplendent vault gives an indefinite depth to the celestial ocean that deepens over our heads. But let us here leave the magnificence of the spectacle to study it in its most minute details.

Let us commence with the appearances. A characteristic common to all the stars is an incessant and very rapid change of brightness, which has received the name of scintillation. This is accompanied by variations of color equally rapid, due to the same cause as the successive disappearances and reappearances. All stars scintillate, whatever may be their brilliancy, at least in our temperate regions. But the intensity of this luminous movement is not the same in all, and it varies, moreover, both with the degree of purity of the sky, the elevation of the[54] stars above the horizon, and the temperature of the night.

According to Arago, scintillation is due to the difference of velocity of the various colored rays traversing the unequally warm, unequally dense, unequally humid atmospheric strata. Thus, in tropical regions, where the atmospheric strata are more homogeneous, scintillation is rarely observed in stars the elevation of which above the horizon is more than 15°, or the sixth of the distance of the horizon from the zenith. “This circumstance,” says Humboldt, “gives to the celestial vault of these countries a particularly calm and soft character.”

Another specific character of the stars is that their diameters are without appreciable dimensions. To the naked eye, this distinction would be insufficient, since, the moon and the sun excepted, the most considerable planets have not sensible diameters. But, while the magnifying power of optical instruments shows us the principal planets under the form of clearly defined disks, the most powerful glasses only show a star as a luminous point. The distance which separates us from these bodies is so great that there is nothing to astonish us in such a result.

Wollaston affirms that the apparent diameter of the most brilliant star in the heavens, Sirius, is not more than the fiftieth part of a second of an arc. But let us hasten to say that this result still leaves a good margin as to the real dimensions of the star, since, at the distance of Sirius, an apparent diameter would represent a real diameter of 11,000,000 miles; that is, twelve times the diameter of our sun.

[55]

Let us add, lastly, that the absence of appreciable dimensions does not suffice to distinguish absolutely the stars from the planets, since a certain number of the latter, as we have before seen, appear in telescopes only as simple luminous points. Let us come, then, to a permanent specific characteristic, the knowledge of which will always prevent us from confounding a star with one of the known or unknown bodies which form part of our solar group. This characteristic is as follows:

The stars, properly so called, preserve among themselves—nearly enough for our present purpose—the same relative distances. They form, then, on the celestial vault apparent groups, the configuration of which is nearly invariable. Centuries must elapse to show a change of form, unless we employ extremely delicate measures. A planet, on the contrary, moves rapidly across these groups, to such a degree that, in the interval of a night, or at most of a few nights, this displacement is very perceptible; hence the old denomination of fixed stars, in opposition to the wandering ones, or planets.

We must be careful, however, to guard against assigning to this word a rigidity which it does not possess, for the stars really move with a velocity not inferior to that which animates the members of our system. Their immense distance is the only cause of their apparent immobility, which vanishes when precise observations, embracing a sufficient interval of time—some years, for example—are made.

A fact which strikes every one is the great diversity of brightness in the stars which people the[56] heavens. All degrees of intensity are remarked, from the resplendent light of Sirius to the scarcely perceptible glimmer of those hardly visible to the naked eye.

Whence arises this difference of brightness? This question we can not answer for any star in particular, but it is easy to imagine that it may result from various circumstances, such as their less or greater distance, the real and various dimensions of the bodies, and, lastly, the intrinsic brightness of the light peculiar to each. However this may be, astronomers without regard to the unknown causes which may influence the intensity of the stellar light, have divided stars into classes or magnitudes; and when we speak of a star of the first, second, or fifth magnitude, it is understood that this way of speaking refers only to the apparent brightness, and that

nothing is affirmed either as to the real dimensions or distance, or even intrinsic brightness.

Besides, as the stars, arranged in the order of their brightness, would form a progression decreasing by imperceptible degrees, the classes adopted are themselves conventional and arbitrary. The first six magnitudes comprise all stars visible to the naked eye. But the use of the most powerful telescopes brings to view stars of feebler light, descending to the sixteenth and seventeenth magnitudes. In truth, the progression has no inferior limit: it extends more and more in proportion as the progress of the optician's art increases the penetrating power of our instruments.

To gain an idea of the respective intensities of the light emitted by the stars of the first six magnitudes,[57] following the scale adopted by astronomers, the accompanying illustration (Fig. 1), should be inspected; in it the stars are figured by disks, the surfaces of which are in proportion to their brilliancy.

But, we repeat, it must not be thought that the stars ranked in the same class are, on that account, of the same brightness. Thus the light of Sirius is estimated at four times the star Alpha Centauri; but both, nevertheless, are included by astronomers in the number of the stars of the first magnitude. Relative star brightness Fig. 1.—Relative Brilliancy of Stars of the first Six Magnitudes

We here give the names of the twenty most brilliant stars of the two hemispheres which it is usual to consider as forming the first class. They are here arranged in the order of their brightness: 1. Sirius 11. Achernar 2. Eta Argus 12. Aldebaran 3. Canopus 13. Beta Centauri 4. Alpha Centauri 14. Alpha Crucis 5. Arcturus 15. Antares 6. Rigel 16. Altair 7. Capella 17. Spica 8. Vega 18. Fomalhaut 9. Procyon 19. Beta Crucis 10. Betelgeuse 20. Pollux

Lastly, Regulus, a bright star in the constellation of the Lion, is also ranked by some astronomers in the[58] first magnitude, while others only admit in this class the first seventeen stars in the above list. These divergences are of no importance.

In proportion as the scale of brilliancy or magnitude is descended, the number of the stars contained in each class rapidly increases. The number of second magnitude stars in the heavens is about 65; of the third, about 200; of the fifth, 1,100; and of the sixth magnitude, 3,200. Adding these numbers together, we obtain a few over 5,000 stars of the first six magnitudes, and these comprise very nearly all those that can be seen with the naked eye.

The smallness of this number nearly always astonishes those who have not tried to form an exact estimate of the number of stars which shine in the celestial vault on the most favorable nights.

The aspect of the multitude of sparkling points which are scattered over the sky makes us disposed to believe that they are innumerable, and to be counted, if not by millions, at all events by hundreds of thousands. This is, nevertheless, an illusion. All observers who have taken the trouble to make an exact enumeration of the stars visible to the naked eye have arrived at a maximum of 3,000 as the mean number which can be observed in every part of the heavens, visible at the same time, at the same place; this, of course, is but half of the entire heavens.

Argelander has published an exact catalogue of the stars visible on the horizon of Berlin during the course of the year. This catalogue comprises 3,256 stars. According to Humboldt, there are 4,146 visible on the horizon of Paris in the whole course of[59] the year; and as this number increases in proportion as we approach the Equator, that is to say, in proportion as the double movement of the earth unfolds to us during a year a more extensive portion of the heavens, 4,638 stars are already visible to the naked eye on the horizon of Alexandria.

We repeat, the maximum number is comprised between 5,000 and 6,000 stars for the entire heavens, including those seen by the most piercing and most accustomed eyes in the best nights for observation. When the atmosphere is lit up by the moon, or by twilight, or, as happens in the great centres of population, by the illumination of the houses and streets, the lowest magnitude stars are effaced altogether, and the number of those visible is consequently much more limited. We may add in conclusion, that the more the scintillation, the more easy it is to distinguish very faint stars.

A word now on the number of stars that can be seen with the help of the telescope. Here we shall find the numbers which our imagination had erroneously led us to believe are visible to the naked eye.

According to the illustrious director of the Observatory of Bonn—Argelander—the seventh magnitude comprises nearly 13,000 stars; the eighth, 40,000; and, lastly, the ninth, 142,000. The calculations of Struve give the total number of stars visible in the entire heavens by the aid of Sir William Herschel's 20-foot reflector as more than 20,000,000. But, without doubt, these approximate numbers are much below the real ones. It will be seen, besides, that the richness of the heavens in stars is very unequal.[60] The

bright zone known under the name of the Milky Way alone contains, according to Herschel, 18,000,000. THE LUCID STARS.—J. E. Gore

The term “lucid” has been applied to the stars visible to the naked eye, without optical aid of any kind.[4] Many people think that the number of stars visible in this way is very large. But in reality the number visible to the naked eye is comparatively small. Some persons are, of course, gifted with very keen eyesight—“miraculous vision” it is sometimes called—and can see more stars than others; but to average eyesight the number visible in this way, and which can be individually counted, is very limited. The famous Hipparchus formed a catalogue of stars in the year 127 B. C. This presumably contained all the most conspicuous stars he could see in his latitude, and it includes only 1,025 stars. Al-Sûfi, the Persian astronomer, in his Description of the Fixed Stars, written in the Tenth Century, describes the positions of only 1,018 stars, although he refers to a number of other faint stars, of which he does not record the exact places. Pliny thought that about 1,600 stars were visible in the sky of Europe.

In modern times, however, a considerable number of fainter stars have been recorded as visible to the naked eye. The famous German astronomer, Heis, who had keen eyesight, records the positions of 3,903[61] stars north of the Equator, and 1,040 between the Equator and 20 degrees south declination, or a total of 4,943 stars between the North Pole and 20 degrees south of the Equator. This would, I find, give a total of about 7,366 stars for both hemispheres if the stars were equally distributed. Behrmann, in his Atlas of Southern Stars, between 20 degrees south declination and the South Pole, shows 2,344 stars as visible to the naked eye. This would give a total of 7,124 for both hemispheres. The actual number seen by Heis and Behrmann in both hemispheres is 4,943 + 2,344, or 7,287 stars. The Belgian astronomer, Houzeau, published a catalogue and atlas of the stars in both hemispheres, made from his own observations in Jamaica and South America, and finds a total of 5,719 stars in the whole sky. As all these observers had good eyesight, we may take a mean of the above results as the total number visible to the naked eye in the whole star sphere. This gives 6,874 stars, or in round numbers we may say that there are about 7,000 stars visible to average eyesight in both hemispheres. This gives, of course, about 3,500 stars to one observer at the same time at any point on the earth’s surface.

As the whole star sphere contains an area of 41,253 square degrees, we have an average of one star to six square degrees. In other words there is, on an average, one lucid star in a space equal to about thirty times the area covered by the full moon! This result may seem rather surprising considering the apparently large number of stars visible to the naked eye on a clear night, but the fact can not be denied.[62] The stars are not, of course, equally distributed over the surface of the sky, but are gathered together in some places, and sparsely scattered in others, and this may perhaps help to give the impression of a greater number than there really are.

That the stars are of various degrees of brightness was recognized by the ancient astronomers. Ptolemy divided them into six classes, the brightest being called first magnitude, those considerably fainter the second, those much fainter still the third, down to the sixth magnitude, which were supposed to be the faintest just visible to the naked eye on a clear moonless night. Ptolemy only recorded whole magnitudes, but Al-Sûfi, in the Tenth Century, divided these magnitudes, for the first time, into thirds. Thus a star slightly less than an average star of the second magnitude he called 2—3, that is nearer in brightness to 2 than to 3; one a little brighter than the third he recorded as 3—2, or nearer to 3 than to 2, and so on. This method has been followed by Argelander, Behrmann, Heis, and Houzeau, but in the photometric catalogues of Harvard, Oxford, and Potsdam the magnitudes are measured in decimals of a degree. This has been found necessary for greater accuracy, as the heavens contain stars of all degrees of brightness.

The term “magnitude” means the ratio between the light of a star of a given magnitude and that of another exactly one magnitude fainter. This ratio has been variously estimated by different astronomers, and ranges from 2.155, found by Johnson in 1851, to 3.06, assumed by Pierce in 1878. The value[63] now universally adopted by astronomers is 2.512 (of which the logarithm is 0.4). This number is nearly a mean of all the estimates made, and agrees with the value found by Pogson in 1854 by means of an oil flame, and by Rosen with a Zöllner photometer in 1870. It simply means that an average star of the first magnitude is 2.512 times the brightness of a star of the second magnitude; a star of the second, 2.512 times brighter than one of the third, and so on. This makes a star of the first magnitude just 100 times brighter than one of the sixth.

There are several stars brighter than an average star of the first magnitude, such as Aldebaran. These are Sirius, which is nearly 11 times brighter than Aldebaran (according to the revised measures at Harvard); Canopus, the second brightest star in the heavens, and about two magnitudes brighter than Aldebaran; Arcturus, Capella, Vega, Alpha Centauri, Rigel, Procyon, Alpha Eridani, Beta Centauri, and Alpha Orionis. Al-Sûfi rated 13 stars of the first magnitude, visible at his station in Persia, and Halley

enumerates 16 in the whole sky. According to the Harvard photometric measures, there are 13 stars in both hemispheres brighter than Aldebaran, which is rated 1.07.

As average stars of the different magnitudes the following may be taken as examples, derived from the Harvard measures: First magnitude, Aldebaran and Spica; second magnitude, β Aurigæ and β Canis Majoris; third magnitude, ι Aurigæ and β Ophiuchi; fourth magnitude, θ Herculis and ε Draconis; and fifth magnitude, ρ Ursæ Majoris and ω Sagittarii.[64] Stars of about the sixth magnitude are, of course, numerous, and lie near the limit of naked-eye vision for average eyesight, although on clear moonless nights still fainter stars may be “glimpsed” by keen-eyed observers.

The stars have been divided into groups and constellations, now chiefly used for the purpose of reference, but in ancient times they were associated with the imaginary figures of men and animals, etc. The origin of these constellation figures is doubtful, but they are certainly of great antiquity. Ptolemy’s constellations were 48 in number, but different writers from the First Century B. C. give different numbers, ranging from 43 to 62. Bayer’s Uranometria, published in 1603, contains 60, 12 new constellations in the Southern Hemisphere having been added by Theodorus to Ptolemy’s original 48.

The figures representing the constellations were originally drawn on spheres, or celestial globes, as they are now called. The ancient astronomers attributed the invention of the sphere to Atlas. It seems certain that a celestial sphere was constructed by Eudoxus in the Fourth Century B. C. Strabo speaks of one made by Krates about the year 130 B. C., and according to Ovid, Archimedes had constructed one at a considerably earlier period. None of these ancient spheres has been preserved. There is, however, in the Vatican a fragment in marble of a Græco-Egyptian planisphere, and a globe in the museum of Arolsen, but these are of much later date. Our knowledge of the original constellation figures is derived from the accounts given by Ptolemy and[65] his successors, and from a few globes which only date back to the Arabian period of astronomy. Among the Arabian globes still existing the most famous is one made of copper, and preserved in the Borgia Museum at Velletri in Italy. It is supposed to have been made by a person called Caisar, who was executed by the Sultan of Egypt in A. D. 1225. The most ancient of all is one discovered some years ago at Florence. It is supposed to date back to A. D. 1081, and to have been made by Meucci. There is also one in the Farnese Museum at Naples, made in A. D. 1225. Of modern celestial globes the oldest is one made by Jansson Blaeu in 1603. This gives all the constellations of the Southern Hemisphere as well as the Northern.

Ptolemy’s figures of the constellations were restored by the famous painter Albert Dürer of Nuremberg in 1515. The figures on modern globes and maps have been copied from this restoration. Dürer’s maps are now very rare.

In 1603, an atlas was published by Bayer. This was the first atlas to show the southern sky, and the first to designate the brightest stars by the letters of the Greek alphabet.[5] Flamsteed published an atlas in 1729. Maps and catalogues of the lucid[66] stars have been published in recent times by Argelander, Behrmann, Heis, Houzeau, Proctor, and others. Of these Heis’s is, perhaps, the most reliable, at least so far as accurate star magnitudes are concerned. Houzeau shows both hemispheres, all the stars had been observed by himself in Jamaica and South America. Behrmann’s maps are confined to the Southern Hemisphere, between the South Pole and 20 degrees south of the Equator. The maps of the Uranometria Argentina, made at Cordoba in the Argentine Republic, show all the southern stars to the seventh magnitude, but many of these are beyond the reach of ordinary eyesight.

It is a well-known fact that the planets Venus and Jupiter are bright enough to form shadows of objects on a white background. It has also been found that the brightest stars, especially Sirius, are sufficiently brilliant to cast shadows. Kepler stated that a shadow was formed by even Spica, but I am not aware that this has been confirmed by modern observations.

There are some remarkable collections or clusters of stars visible to the naked eye, of these the Pleiades are probably the best known. To ordinary eyesight 6 stars are visible, but Möstlin, Kepler’s tutor, is said to have seen 14 with the naked eye, and some observers in modern times have seen 11 or 12. Other naked-eye clusters are the Hyades in Taurus, called Palilicium by Halley, and the Præsepe, or Bee-Hive in Cancer. Of larger groups, the Plow or Great Bear, Cassiopeia’s Chair, and Orion are probably known to most people.

[67]

Many of the lucid stars are double, that is, consist of two components, but most of these are only visible in powerful telescopes. There are, however, a few objects visible to the naked eye as double, and these have been called “naked-eye doubles,” although not strictly double in the correct sense of the term.

Ptolemy applied the term double to the star ν Sagittarii, which consists of two stars separated by a distance of fourteen minutes of arc, or about half the apparent diameter of the moon. According to Riccioli, Van der Hove saw two naked-eye doubles, one in Capricornus, 5 to 5½ minutes distant, and the other in the Hyades, 4½ or 5 minutes apart. The one in Capricornus was probably α, and the one in the Hyades θ Tauri. The middle star in the tail of the Great Bear, or handle of the Plow, has near it a small star, Alcor, which to many eyes is distinctly visible without optical aid. The famous Belgian astronomer, Houzeau, who seems to have had excellent sight, saw the star χ Tauri double, and 51 and 56 Tauri separated, also ι Orionis, and others.

Many of the stars are variable in their light, and several hundred of these curious and interesting objects are now known to astronomers. In a few of these the light changes may be followed with the naked eye. It is an interesting question whether any of the lucid stars have disappeared or changed in brightness since the early ages of astronomical observations. Al-Sûfi failed to find seven of Ptolemy's stars, and Ulug Bekh, comparing his observations with the catalogues of Ptolemy and Al-Sûfi, announced[68] twelve cases of supposed disappearance. Some of these may, however, be due to errors of observation. Montanari, writing in 1672, mentions two stars as having disappeared, namely β and γ of the constellation Argo, but these stars are now visible in the positions originally assigned to them.

In a careful examination of Al-Sûfi's description of the stars written in the Tenth Century, and a comparison with modern estimates and measures, I have found several very interesting cases of apparent change in the brightness of the lucid stars. Al-Sûfi was an excellent and careful observer, and as a rule his estimates agree well with modern observations. We can therefore place considerable reliance on his estimates of star magnitudes. The Story of Theta Eridani has been well told by Dr. Anderson, and there seems to be no doubt that this southern star, which is now only of the third magnitude, was a bright star of the first magnitude in Al-Sûfi's time! The following are other interesting cases of apparent change which I have met with in my examination of Al-Sûfi's work. The Pole Star was rated third magnitude by both Ptolemy and Al-Sûfi, but it is now of the second magnitude, or a little less. The star γ Geminorum was rated third magnitude by Ptolemy and Al-Sûfi, or equal to δ Geminorum, but γ is now of the second magnitude, and its great superiority in brightness over δ is noticeable at a glance. Another interesting case is that of ζ and ο Persei, two stars which lie near each other, about seven degrees north of the Pleiades. Al-Sûfi distinctly describes these stars as both of the 3—4 magnitude; but Argelander,[69] Heis, and the photometric measures at Harvard agree in making ζ about one magnitude brighter than ο. The stars being close are easily compared, and their present great difference in brightness is very noticeable. This is one of the most remarkable cases I have met with in Al-Sûfi's work, and strongly suggests variation in ο, as ζ is still about the same brightness as Al-Sûfi made it. The identity of the stars is beyond all doubt, as Al-Sûfi describes their positions very clearly, and says there is no star between them and the Pleiades, a remark which is quite correct for the naked eye. The remarkable decrease in brightness of β Leonis (Denebola) since Al-Sûfi's time has been considered in my paper on Some Suspected Variable Stars. That it was a bright star of the first magnitude is fully proved by the observations of Al-Sûfi and Tycho Brahe. These were careful and accurate observers, and they could not have been mistaken about a star of the first magnitude. β Leonis is now fainter than an average star of the second magnitude, and there can be no reasonable doubt that it has faded considerably since the Tenth Century.

There are some other discrepancies between Al-Sûfi's observations and modern estimates, but the above are perhaps the most remarkable. With reference to lucid stars not mentioned by Al-Sûfi, he has not, I think, omitted any star brighter than the fourth magnitude in that portion of the sky visible from his station. There are, however, a number of stars between the fourth and sixth magnitudes which he does not mention. Of these the brightest[70] seem to be ε Aquilæ, ρ and μ Cygni, and ζ Coronæ Borealis.

With reference to the distribution of the lucid stars in the sky there seems to be a well-marked tendency to congregate on the Milky Way. It is a remarkable fact that of the 15 brightest stars in the heavens, no less than 11 lie on or near the Milky Way, although the space covered by the Galaxy does not exceed one-fifth or one-sixth of the whole sky. From a careful enumeration of the stars in or near the Milky Way which I made some years ago, I found that of stars brighter than the fourth magnitude there are 118 on the Milky Way out of a total of 392, or about 30 per cent. From the Southern catalogue known as the Uranometria Argentina, Colonel Markwick, F.R.A.S., found 121 out of 228 stars to fourth magnitude, or a percentage of 53 per cent. These results seem to show some intimate relation between the lucid stars and the Galaxy. FOOTNOTES:

The earth is forgotten, with its small and ephemeral history. The sun himself, with all his immense system, has sunk in the infinite night. On the wings of inter-sidereal comets we have taken our flight toward the stars, the suns of space. Have we exactly measured, have we worthily realized the road passed over by our thoughts? The nearest star to us reigns at a distance of 275,000 times 37[71] millions of leagues—that is to say, at ten trillions[6] of leagues (about twenty-five billions of miles); out to that star an immense desert surrounds us, the most profound, the darkest, and the most silent of solitudes.

The solar system seems to us very vast, the abyss which separates our world from Mars, Jupiter, Saturn, and Neptune appears to us immense; relatively to the fixed stars, however, our whole system represents but an isolated family immediately surrounding us: a sphere as vast as the whole solar system would be reduced to the size of a simple point if it were transported to the distance of the nearest star. The space which extends between the solar system and the stars, and which separates the stars from each other, appears to be entirely void of visible matter, with the exception of nebulous fragments, cometary or meteoric, which circulate here and there in the immense voids. Nine thousand two hundred and fifty systems like ours (bounded by Neptune), would be contained in the space which isolates us from the nearest star!

If a terrible explosion occurred in this star, and if the sound could traverse the void which separates it from us, this sound would take more than three millions of years to reach us.

It is marvelous that we can perceive the stars at such a distance. What an admirable transparency in these immense spaces to permit the light to pass, without being wasted, to thousands of billions of[72] miles! Around us, in the thick air which envelops us, the mountains are already darkened and difficult to see at seventy miles; the least fog hides from us objects on the horizon. What must be the tenuity, the rarefaction, the extreme transparency of the ethereal medium which fills the celestial spaces!

Let us suppose ourselves, then, on the sun nearest to ours. From there our dazzling furnace is already lost like a little star, hardly recognizable among the constellations: earth, planets, comets sail in the invisible. We are in a new system. If we thus approach each star we find a sun, while all the other suns of space are reduced to the rank of stars. Strange reality!—the normal state of the universe is night. What we call day only exists for us because we are near a star.

The immense distance which isolates us from all the stars reduces them to the state of motionless lights apparently fixed on the vault of the firmament. All human eyes, since humanity freed its wings from the animal chrysalis, all minds since the minds have been, have contemplated these distant stars lost in the ethereal depths; our ancestors of Central Asia, the Chaldeans of Babylon, the Egyptians of the Pyramids, the Argonauts of the Golden Fleece, the Hebrews sung by Job, the Greeks sung by Homer, the Romans sung by Virgil—all these earthly eyes, for so long dull and closed, have been fixed from age to age on these eyes of the sky, always open, animated, and living. Terrestrial generations, nations and their glories, thrones and altars have vanished: the sky of Homer is always there. Is it astonishing that[73] the heavens were contemplated, loved, venerated, questioned, and admired even before anything was known of their true beauties and their unfathomable grandeur?

Better than the spectacle of the sea calm or agitated, grander than the spectacle of mountains adorned with forests or crowned with perpetual snow, the spectacle of the sky attracts us, envelops us, speaks to us of the infinite, gives us the dizziness of the abyss; for, more than any other, it seizes the contemplative mind and appeals to it, being the truth, the infinite, the eternal, the all. Writers who know nothing of the true poetry of modern science have supposed that the perception of the sublime is born of ignorance, and that to admire it is necessary not to know. This is assuredly a strange error, and the best proof of it is found in the captivating charm and the passionate admiration which divine science now inspires, not in some rare minds only, but in thousands of intellects, in a hundred thousand readers impassioned in the search for truth, surprised, almost ashamed at having lived in ignorance of and indifference to these splendid realities, anxious to incessantly enlarge their conception of things eternal, and feeling admiration increasing in their dazzled minds in proportion as they penetrate further into Infinitude. What was the universe of Moses, of Job, of Hesiod, or of Cicero, compared to ours! Search through all the religious mysteries, in all the surprises of art, painting, music, the theatre, or romance, search for an intellectual contemplation which produces in the mind the impression of truth,[74] of grandeur, of the sublime, like astronomical contemplation! The smallest shooting star puts to us a question which it is difficult not to hear; it seems to say to us, What are we in the universe? The comet opens its wings to carry us into the profundities of space: the star which shines in the depths of the heavens shows us a distant sun surrounded with unknown humanities who warm themselves in his rays. Wonderful, immense, fantastic spectacles, they charm by their captivating beauty and transport into the majesty of the unfathomable the man who permits himself to soar and wing his flight to Infinitude. Nel ciel che più della sua luce prende Fu' io, e vidi cose che ridire Né sa, né può qual di lassù discende.

“I have ascended into the heavens, which receive most of His light, and I have seen things which he who descends from on high knows not, neither can repeat,” wrote Dante in the first canto of his poem on “Paradise.” Let us, like him, rise toward the celestial heights, no longer on the trembling wings of faith, but on the stronger wings of science. What the stars would teach us is incomparably more beautiful, more marvelous, and more splendid than anything we can dream of. Northern hemisphere Chart of the Northern Constellations Showing the principal Stars of the first five magnitudes visible to the naked eye

Among the innumerable army of stars which sparkle in the infinite night, the gaze is especially arrested by the most brilliant lights and by certain groups which vaguely present a mysterious bond between the worlds of space. These groups have been[75] noticed at all epochs, even among the rudest races of men, and from the earliest ages of humanity they have received names, usually derived from the organic kingdom, which give a fantastic life to the solitude and the silence of the skies. Thus were early distinguished the seven stars of the North, or the Chariot, of which Homer speaks; the Pleiades, or the “Poussinière”; the giant Orion; the Hyades in the head of Taurus; Boötes, near the Chariot or Great Bear. These five groups were already named more than 3,000 years ago, and so were the brightest stars of the sky, Sirius and Arcturus, etc.

The epoch of the formation of the constellations is unknown, but we know that they were established successively. The centaur Chiron, Jason’s tutor, has the reputation of having first divided the sky on the sphere of the Argonauts. But this is mythology; and, besides, Job lived before the epoch at which Chiron is supposed to have flourished, and Job had already spoken of Orion, the Pleiades, and the Hyades 3,000 years ago. Homer also speaks of these constellations in describing the famous shield of Vulcan. “On its surface,” says he, “Vulcan, with a divine intelligence traces a thousand varied pictures. He represents the earth, the heavens, the sea, the indefatigable sun, the moon at its full, and all the stars which wreath the sky: the Pleiades, the Hyades, the brilliant Orion, the Bear, which they also call the Chariot, and which revolves round the pole; this is the only constellation which does not dip into the ocean waves” (Iliad, chapter xviii.).

Several theologians have affirmed that it was[76] Adam himself, in the terrestrial paradise, who gave their names to the stars; the historian Josephus assures us that it was not Adam, but his son Seth, and that in any case astronomy was cultivated long before the Deluge. This nobility is sufficient for us.

Attentive observation of the sky also noticed from the beginning the beautiful stars Vega of the Lyre, Capella of Auriga, Procyon of the Little Dog, Antares of the Scorpion, Altair of the Eagle, Spica of the Virgin, the Twins, the Chair of Cassiopeia, the Cross of the White Swan, stretched in the midst of the Milky Way. Although noticed at the epoch of Hesiod and Homer, these constellations and stars were probably not yet named, because doubtless men had not yet felt the necessity of registering them for any application to the calendar, to navigation, or to voyages.[7]

[77]

At the epoch when the maritime power of the Phœnicians was at its apogee, about 3,000 years ago, or twelve centuries before our era, it was the star β of the Little Bear which was the nearest bright star to the pole, and the skilful navigators of Tyre and Sidon (O purpled kings of former times! what remains of your pride?) had recognized the seven stars of the Little Bear, which they named the Tail of the Dog, Cynosura; they guided themselves by the pivot of the diurnal motion, and during several centuries they surpassed in precision all the mariners of the Mediterranean. The Dog has given place to a Bear, doubtless on account of the resemblance of the configuration of these seven stars to the seven of the Great Bear, but the tail remains long and curled up, in spite of the nature of the new animal.

Thus the stars of the North at first served as points of reference for the first men who dared to venture on the seas. But they served at the same time as guides on the mainland for the nomadic tribes who carried their tents from country to country. In the midst of savage nature, the first warriors themselves had nothing but the Little Bear to guide their steps.

Imperceptibly, successively, the constellations were formed. Some groups resemble the names which they still bear, and suggested their denomination to the men of ancient times, who lived in the midst of nature and sought everywhere for relations with their daily observations. The Chariot; the Chair; the Three Kings, also named the Rake; Jacob’s Staff and the Belt of Orion; the Pleiades, or the Hen and Chickens; the Arrow (Sagitta); the[78] Crown; the Triangle; the Twins; the Dragon; the Serpent; and even the Bull, the Swan, the Giant Orion, the Dolphin, the Fishes, the Lion, Water and Aquarius (the Water-bearer), etc., have given rise to the analogy. These resemblances are sometimes vague and far-fetched, like those we find in the clouds; but it appears much more natural to admit this origin than to suppose, with the classic authors, that these names were suggested by the concordance between the seasons or the labors of the fields and the presence of the stars above the horizon. That the name of the Balance

(Libra) was given to the constellation of the equinox because then the days are equal, seems to us more than questionable; that Cancer (the Crab) signifies that the sun goes back to the solstice, and that the Lion has for its object to symbolize the heat of summer, and Aquarius the rain and inundations, appears to us no less imaginary. However, they have also had other origins. Thus, the Great Dog Sirius certainly announced the rising of the Nile and the dog-days (which remain in our calendar as a fine type of anachronism). Poetry, gratitude, the deification of heroes, mythology, afterward transferred to the sky the names of personages and sovereigns—Hercules, Perseus, Andromeda, Cepheus, Cassiopeia, Pegasus; later, in the Roman epoch, they added the Hair of Berenice and Antinous; later still, in modern times, they added the Southern Cross, the Indian, the Sculptor's Workshop (Cœlum), the Lynx, the Giraffe (Camelopardus), the Greyhounds (Canes Venatici), the Shield of Sobieski, and the little Fox (Vulpecula).[79] They even placed in the sky a Mountain, an Oak, a Peacock, a Swordfish, a Goose, a Cat, a Crane, a Lizard, and a Fly, for which there was no necessity.

This is not the place to describe and draw in detail all these constellations, with their more or less strange figures. The important point for us here is to form a general idea.

The sky remains divided into provinces, each of which continues to bear the name of the primitive constellation. But it is important to understand that the positions of the stars themselves, as we see them, are not absolute, and that the different configurations which they may show us are only a matter of perspective. We already know that the sky is not a concave sphere on which brilliant nails could be attached; that it is not a species of vault; that an immense infinite void envelops the earth on all sides, in all directions. We know also that the stars, the suns of space, are scattered at all distances in the vast immensity. When, therefore, we remark in the sky several stars near each other, that does not imply that these stars form the same constellation, that they are on the same plane, and at an equal distance from the earth. By no means; the arrangement which they assume to our eyes is but an appearance caused by the position of the earth relatively to them. This is a mere matter of perspective. If we could leave our world, and transport ourselves to a point in space sufficiently distant, we should see a variation in the apparent arrangement of the stars so much the greater as our station of observation were more distant from where we are at present. A moment's[80] reflection is sufficient to convince us of this fact, and save us from insisting further on this point.

Once these illusions are appreciated at their true value, we can begin the description of the figures with which the ancient mythology has constellated the sphere. A knowledge of the constellations is necessary for the observation of the heavens and for the researches which a love of the sciences and curiosity may suggest; without it we find ourselves in an unknown country, of which the geography has not been made, and where it would be impossible to know our exact position. Let us make, then, this celestial geography; let us see how to find our way, in order to read readily in the great book of the heavens.

There is a constellation which everybody knows; for greater simplicity we will begin with it. It will serve us well as a point of departure from which to go to the others, and as a point of reference to find its companions. This constellation is the Great Bear, which has also been named the Chariot of David.

It may well boast of being celebrated. If, notwithstanding its universal notoriety, some of our readers have not yet made its acquaintance, the following is a description by which they may recognize it. Stars of Great Bear Fig. 2

Turn yourself toward the north—that is to say, opposite to the point where the sun is found at noon.[81] Whatever may be the season of the year, the day of the month, or the hour of the night, you will always see there a large constellation formed of seven fine stars, of which four are in a quadrilateral, and three at an angle with one side; all are arranged as we see in Fig. 2.

You have all seen it, have you not? It never sets. Night and day it watches above the northern horizon, turning slowly in twenty-four hours round a star of which we shall speak directly. In the figure of the Great Bear, the three stars of the extremity form the tail, and the four in the quadrilateral lie in the body. In the Chariot, the four stars of the quadrilateral form the wheels, and the other three the pole, the horses, or the oxen. Above the second of these latter stars, ζ, good sight distinguishes quite a little star named Alcor, which is also called the Cavalier. It serves to test the power of the sight. Each star is designated by a letter of the Greek alphabet: α and β mark the first two stars of the quadrilateral, γ and δ the two following, ε, ζ, η, the three of the pole. Arabic names have also been given to these stars, which we will pass in silence, because they are generally obsolete, with the exception, however, of that of the second horse—Mizar. With reference to the Greek letters, many persons think that it would be preferable to suppress them and to replace them by numbers. But this would be impossible in the practice of astronomy; and, moreover, inevitable confusion would result, on account of the numbers which the stars bear in the catalogues.

The Latins gave to plowing oxen the name of[82] triones; instead of speaking of a chariot and three oxen, they came to call them the seven oxen (septemtriones). From this is derived the word septentrion, and there are now doubtless but few persons who, in writing this word, know that they are speaking of seven oxen. It is the same, however, with many other words. Who remembers, for example, in using the word tragedy, that he speaks of a song of a goat: tragôs-ode?

Let us go back to Fig. 2. If we draw a straight line through the two stars marked α and β which form the right side of the square, and produce it beyond α to a distance equal to five times that from β to α, or to a distance equaling that from α to the end of the tail, η, we find a star a little less brilliant than at the extremity of a figure similar to the Great Bear, but smaller and pointing in the opposite direction. This is the Little Bear, or the Little Chariot, also formed of seven stars. The star to which our line leads us—that which is at the tip of the tail of the Little Bear, or at the end of the pole of the Little Chariot—is the polar star. Pole star Fig. 3

The polar star enjoys a certain fame, like all persons who are distinguished from the common, because,[83] among all the bodies which scintillate in the starry night, it alone remains motionless in the heavens. At any moment of the year, by day or by night, when you observe the sky, you will always find it. All the other stars, on the contrary, turn in twenty-four hours round it, taken as the centre of this immense vortex. The pole star remains motionless at the pole of the world, from whence it serves as a fixed point to navigators on the trackless ocean, as well as to travelers in the unexplored desert. Square of Pegasus Fig. 4

In looking at the pole star, motionless in the midst of the northern region of the sky, we have the south behind us, the east to the right, the west to the left. All the stars turn round the pole star in a direction contrary to that of the hands of a watch; they should, then, be recognized according to their mutual relations rather than by reference to the cardinal points.

On the other side of the pole star, with reference to the Great Bear, is found another constellation which[84] we can also recognize at once. If from the middle star, δ, we draw a line to the pole, and produce this line by the same distance (see Fig. 3), we arrive at Cassiopeia, formed of five principal stars arranged somewhat like the strokes of the letter M. The little star χ, which completes the square, gives the constellation the form of a chair. This group assumes all possible positions in turning round the pole; it is found sometimes above, sometimes below, sometimes to the right, and sometimes to the left; but it is always easily recognized, for, like the preceding group, it never sets, and is always opposite to the Great Bear. The pole star is the axle round which both these constellations turn. Pleiades; Pegasus Fig. 5 Fig. 6

If, now, we draw from the stars α and δ of the Great Bear two lines through the pole, and produce them beyond Cassiopeia, we come to the Square of Pegasus (see Fig. 4), which shows a line of three stars somewhat similar to the tail of the Great Bear. These three stars belong to Andromeda, and lead to another constellation, Perseus. The last star of the Square of Pegasus is, as we see, the first (α) of Andromeda; the three others are named γ, α, and β.[85] To the north of β of Andromeda is found, near a little star, ν, an oblong nebula, which can be distinguished with the naked eye. In Perseus, α, the brightest—on the prolongation of the three principal stars of Andromeda—appears between two others less brilliant, which form with it a concave arc very easy to distinguish. This arc serves us for a new alignment. Producing it in the direction of δ, we find a very brilliant star of the first magnitude; this is Capella (the Goat). Forming a right angle with this prolongation toward the south we come to the Pleiades (Fig. 5). Not far from that is a variable star, Algol, or the Head of Medusa, which varies from the second to the fourth magnitude[8] in 2 days, 20 hours, 48 minutes, 51 seconds. We may add, that in this region the star γ of Andromeda is one of the most beautiful double stars (it is even triple). Lyre; Altair Fig. 7 Fig. 8

If, now, we produce beyond the Square of Pegasus (Fig. 6) the curved line of Andromeda, we reach the Milky Way, and we meet in these parts Cygnus, like a cross; the Lyre, where Vega shines (Fig. 7); the Eagle, and Altair (not Atair, as it is sometimes written) with two companions (Fig. 8).

[86]

Such are the principal constellations visible in the circumpolar regions on one side; we shall make a fuller acquaintance with them directly. While we are tracing the lines of reference let us still have a little patience and finish our summary review of this part of the sky. Arcturus Fig. 9

Look now at the side opposite to that of which we have just spoken. Let us return to the Great Bear. Producing the tail along its curve, we find at some distance from that a star of the first magnitude, Arcturus (Fig. 9), or α of Boötes. A little circle of stars which we see to the left of Boötes constitutes the Northern Crown (Corona Borealis). In the month of May, 1866, there was seen shining there a fine star, the brightness of which lasted only fifteen days. The constellation of Boötes is traced in the form of a pentagon.

The stars which compose it are of the third magnitude, with the exception of Arcturus, which is of the first. This is one of the nearest to the earth; at least, it is one of a small number whose distance has been measured. It shines with a beautiful golden yellow color. The star ε, which we see above it, is double—that is to say, the[87] telescope resolves it into two distinct stars, one yellow, the other blue. Vega; Arcturus; Pole star Fig. 10.

This technical description is far from the poetry of Nature; but it is especially important here to be clear and precise. Let us suppose ourselves, however, under the starry vault on a beautiful summer's night, splendid and silent, and let us consider that each of these points which we seek to recognize is a world, or rather a system of worlds. Look at this equilateral triangle (Fig 10); it permits us to cast our eyes successively on three important suns: Vega of the Lyre, Arcturus of Boötes, and the pole star, which watches above the solitudes of our mysterious North Pole. Many martyrs of science have died looking at it! In twelve thousand years our descendants[88] will see the Lyre at the pole, ruling the harmony of the heavens.

The stars which are near the pole, and which have for that reason received the name of circumpolar stars, are distributed in the groups which have just been indicated. I earnestly invite my readers to profit by fine evenings, and try to find for themselves these constellations in the sky.

We have here the principal stars and constellations of the Northern Hemisphere, the North Pole being at the centre of the circle. We come now in the order of our description to the twelve constellations of the zodiacal belt, which makes the circuit of the sky, inclined at 23° to the Equator, and of which the ecliptic, the apparent path of the sun, forms the centre line.

The name of zodiac, given to the zone of stars which the sun traverses during the course of the year, comes from ζ■δια, animals, an etymology which is due to the species of figures traced on this belt of stars. Animals, in fact, predominate in these figures. The entire circumference of the sky has been divided into twelve parts, which have been named the twelve signs of the zodiac; our ancestors called them the "houses of the sun," or "the monthly abodes of Apollo," because the day star visits them each month, and returns every spring to the beginning of the zodiacal city. Two memorable Latin verses of the poet Ausonius present to us these twelve signs in the order in which the sun travels through them, and this still appears the easiest method of learning them by heart.

[89] Sunt Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libraque, Scorpius, Arciteneus, Caper, Amphora, Pisces;

or, in English, the Ram ■■, the Bull ■■, the Twins ■■, the Crab ■■, the Lion ■■, the Virgin ■■, the Balance ■■, the Scorpion ■■, the Archer ■■, Capricornus ■■, Aquarius ■■, and the Fishes ■■. The signs placed beside these names are a vestige of the primitive hieroglyphics which described them: ■■ represents the horns of the Ram, ■■ the head of the Bull; ■■ is a stream of water, etc.

If we now know our northern sky, if its most important stars are sufficiently noted down in our mind, with the reciprocal relations which they preserve among themselves, we have no more confusion to fear, and it will be easy to recognize the zodiacal constellations. This zone may be of use to us as a line of division between the north and the south. Here is a description of it:

The Ram, which, moving in front of the herd, and regulating, so to say, the march, opens the series. This constellation has in itself nothing remarkable; the brightness of its stars indicates the base of one of the horns of the leader of the sheep; it is but of the second magnitude. After the Ram comes the Bull. Admire on a fine winter's night the charming Pleiades which scintillate in the ether; not far from them shines a fine red star—this is the eye of the Bull—Aldebaran, a star of the first magnitude and one of the finest of our sky. We now arrive at the Twins, whose heads are marked by two fine stars of the second magnitude, situated a little above a star of the first magnitude—Procyon, or the Little Dog; Cancer, or the Crab, a constellation very little conspicuous (its most visible stars are but of the fourth magnitude, and occupy the body of the animal); the Lion, a fine constellation, marked by a star of the first magnitude, Regulus, by one of the second, β, and by several others of the second and third magnitudes arranged in a trapezium; the Virgin, indicated by a very brilliant star of[90] the first magnitude; Spica, situated in the neighborhood of a star, also of the first magnitude, Arcturus, which is found on the prolongation of the tail of the Great Bear; the Balance (Libra), indicated by two stars of the second magnitude, which would exactly resemble the Twins if they were nearer to each other; the Scorpion, a remarkable constellation; a star of the first magnitude, of a fine red color, marks the Heart (Antares), in the middle of two stars of the third magnitude, above which are three bright stars arranged in a diadem; Sagittarius, the Archer, of which the arrow, indicated by three stars of the second and third magnitudes, is pointed toward the tail of the Scorpion; Capricornus, a constellation not conspicuous, which is recognized by two stars of the third magnitude very near each other, and representing the base of the horns of the hieroglyphic animal; Aquarius, indicated by three stars of the third magnitude arranged in a triangle, of which the most northern occupies a point on the equator; Pisces, the Fishes, composed of stars, barely conspicuous, of the third to fourth

magnitudes, situated to the south of a large and magnificent quadrilateral—the Square of Pegasus—of which we have already spoken.

We have now enumerated the zodiacal constellations in the order of the direct motion (from west to east) of the sun, moon, and planets which traverse them. They marked at the epoch of their formation, the monthly passage of the sun into each of them. The distribution of the stars in figurative groups was the first truly hieroglyphical writing; it was engraved on the firmament in indelible characters.

The zodiac has played a great part in the ancient history of every nation—in the formation of the calendar, in the appointment of public festivals, and in the constitution of eras. The zodiac of Denderah, discovered by the French savants in Egypt at the end of the Eighteenth Century, was at first believed to have an antiquity of 15,000 years; but it is now proved that it is necessary to deduct from that number[91] of years half the cycle of precession—that is to say, nearly 13,000 years—which brings down the date of this sculpture to 2,000 years before our epoch; and this in fact corresponds with the evidence of archæology. It is remarkable that all the ancient zodiacs and calendars which have been preserved to us begin the year with the constellation of the Bull, as we have already noticed. The zodiac of the Elephanta Pagoda (Salsette) has at the head of the procession the sign of the sacred Bull, the ox Apis, Mithra—of which the promenade of the fat ox, which is still performed in the environs of Paris, is a vestige. The ceiling of a sepulchral chamber at Thebes shows the Bull at the head of the procession. The zodiac of Esne, the astronomical picture discovered by Champollion in the Ramesseum of Thebes, carries us back to the same origin, between two and three thousand years before our era; Biot supposes the date of this to be the year 3285, the vernal equinox passing through the Hyades on the forehead of Taurus. Father Gaubil has proved that from ancient times the Chinese have referred the beginning of the apparent motion of the sun to the stars of Taurus; and we have a Chinese observation of the star η of the Pleiades as marking the vernal equinox in the year 2357 before our era. Hesiod sings of the Pleiades as ruling the labors of the year, and the name of Vergilia, which the ancient Romans gave them, associates them with the beginning of the year in spring. Arabic zodiac Fig. 11

Without entering into any details of the different zodiacs which have been preserved to us from the[92] most ancient and diverse nations, a glance at those which are reproduced here will lead us to appreciate the part which they have played in ancient religions. Several zodiacal signs have become veritable gods. The zodiac represented by Fig. 11 was engraved, in the Thirteenth Century, on an Arabic magic mirror, and dedicated to the sovereign prince Aboulfald, “Victorious Sultan, Light of the World,” if we are to believe the bombastic inscription which[93] encircles it. Fig. 12 shows an ancient Hindoo zodiac. Fig. 13 shows a Chinese zodiac stamped upon a talisman, even now in use. The twelve signs differ from ours; they are: the Mouse, the Cow, the Tiger, the Rabbit, the Dragon, the Serpent, the Horse, the Ram, the Ape, the Hen, the Dog, and the Pig. Fig. 14 represents a Chinese medal, on which we see the constellation Teou, the Great Bear[9] (which they call the Bushel), the Serpent, the Sword, and the Tortoise. This is a talisman intended to give courage;[94] it appears that it is in great demand among the Chinese, and is as well circulated as the medals of the Immaculate Conception are in France. Hindoo zodiac Fig. 12.—Ancient Hindoo Zodiac

Of all the zodiacal constellations, that of the Bull has played the principal rôle in ancient myths; and in this constellation it was the sparkling cluster of the Pleiades which appears to have regulated the year and the calendar among all the ancient nations. The Mosaic deluge itself, referred to 17 Athir (November), in commemoration of an important inundation, had its date coincident with the appearance of the Pleiades.[10] Chinese zodiac Fig. 13.—Chinese Zodiac, from Fig. 14.—Chinese Medal, showing a Talisman the Great Bear

But we forget the stars. If our descriptions have been carefully followed, the reader will now know the zodiacal constellations as well as those of the north. There remains but little to do to know the entire sky. But there is an indispensable addition to be made to what precedes. The circumpolar stars[95] are perpetually visible above the London horizon; at any time of the year when we wish to observe them it is sufficient to turn to the north, and we shall always find them, either above the pole star or below it, to one side or the other, and always maintaining among themselves the relations which we have employed to find them. The stars of the zodiac do not resemble them from this point of view, for they are sometimes above the horizon, sometimes below. It is necessary, then, to know at what epoch they are visible. For this purpose it will be sufficient to remember the constellation which is found in the middle of the sky at nine o’clock in the evening on the first day of each month—that, for example, which crosses at that moment a line descending from the zenith to the south. This line is the meridian, of which we have already spoken; all the stars cross it once a day, moving from east to west—that is to say, from left to right. In indicating each of the constellations which pass at the hour indicated, we also give the centre of the visible constellations.

On January 1 Taurus passes the meridian at 9 o'clock in the evening; notice Aldebaran, the Pleiades. On February 1 the Twins (Gemini) are not yet there; we see them a little to the left. March 1, Castor and Pollux have passed; Procyon to the south, the little stars of the Crab (Cancer) to the left. April 1, the Lion, Regulus. May 1, β of the Lion, Berenice's Hair. June 1, Spica of the Virgin, Arcturus. July 1, the Balance (Libra), the Scorpion. August 1, Antares, Ophiuchus. September 1, Sagittarius, Aquila. October 1, Capricornus, Aquarius. November 1, Pisces, Pegasus. December 1, Aries, the Ram.

Our general review of the starry sky must now be completed by the stars of the southern heavens.

[96]

Below Taurus and Gemini, to the south of the zodiac, you notice the giant Orion, who raises his club toward the forehead of the Bull. Seven brilliant stars are here distinguished; two of them, α and β, are of the first magnitude; the five others are of the second magnitude, α and γ mark the shoulders, κ the right knee, β the left knee; δ, ε, ζ mark the belt or girdle. Below this line is a luminous train of three stars, very near each other; this is the Sword. Between the western shoulder and Taurus is seen the Shield, composed of a row of small stars. The head is marked by a little star (λ) of the fourth magnitude.

On a fine winter's night turn toward the south, and you will immediately recognize this giant constellation. The four stars, α, γ, β, κ, occupy the angles of a great quadrilateral. The three others, δ, ε, ζ, are crowded in an oblique line in the middle of this quadrilateral; α, at the northeast angle, is named Betelgeuse (not Beteigeuse, as some books print it); β, at the southeast angle, is called Rigel.

The line of the Belt, produced both ways, passes to the northeast near Aldebaran, the Eye of the Bull, which we know already, and to the southeast near Sirius, the finest star of the sky, which we shall soon consider.

It is during the fine nights of winter that this constellation shines in the evening above our heads. No other season is so magnificently constellated as the months of winter. While nature deprives us of certain enjoyments in one way, it offers us in exchange others no less precious. The marvels of the heavens[97] present themselves from Taurus and Orion in the east to Virgo and Boötes on the west. Of eighteen stars of the first magnitude which are counted in the whole extent of the firmament, a dozen are visible from nine o'clock to midnight, not to mention some fine stars of the second magnitude, remarkable nebulæ, and celestial objects well worthy of the attention of mortals. It is thus that nature establishes a harmonious compensation, and while it darkens our short and frosty days of winter, it gives us long nights enriched with the most opulent creations of the sky.

The constellation of Orion is not only the richest in brilliant stars, but it conceals for the initiated treasures which no other is known to afford. We might almost call it the California of the sky.

To the southeast of Orion, on the line of the Three Kings, shines the most magnificent of all the stars, Sirius, or α of the constellation of the Great Dog. This star of the first magnitude marks the upper eastern angle of a great quadrilateral, of which the base near the horizon of London, is adjacent to a triangle. This constellation rises in the evening at the end of November, passes the meridian at midnight at the end of January, and sets at the end of March. It played the greatest part in Egyptian astronomy, for it regulated the ancient calendar. It was the famous Dog Star; it predicted the inundation of the Nile, the summer solstice, great heats and fevers; but the precession of the equinoxes has in 3,000 years moved back the time of its appearance by a month and a half, and now this fine star announces nothing,[98] either to the Egyptians who are dead or to their successors.

The Little Dog, or Procyon, is found above the Great Dog and below the Twins (Castor and Pollux), to the east of Orion. With the exception of α Procyon, no brilliant star distinguishes it.

Hydra is a long constellation, which occupies a quarter of the horizon, under Cancer, the Lion, and the Virgin. The head, formed of four stars of the fourth magnitude, is to the left of Procyon, on the prolongation of a line drawn from that star to Betelgeuse. The western side of the great trapezium of the Lion, like the line from Castor and Pollux, points to α, of the second magnitude. This is the Heart of Hydra; we remark the asterisms of the second class, Corvus the Crow, and Crater the Cup.

Eridanus, Cetus, Piscis Australis, and the Centaur are the only important constellations which remain to be described. We find them, in the order which we have indicated, to the right of Orion. Eridanus is a river composed of a train of stars winding from the left foot of Orion and losing itself below the horizon. After following long windings, it ends with a fine star of the first magnitude, α Eridani, or Achernar. This is the river into which Phaeton fell when he unskilfully directed the Chariot of the Sun. It was placed in the sky to console Apollo for the death of his son.

To find the Whale (Cetus), we may notice below the Ram a star of the second magnitude which forms an equilateral triangle with the Ram and the Pleiades; this is α of Cetus, or the Jaw; α, μ, ξ, and γ[99] form a parallelogram which represents the head. The base, α, γ, may be produced to a star of the third magnitude, δ, and to a star of the neck marked ο. This star is one of the most curious in the heavens. It is named the Wonderful, Mira Ceti. It belongs to the class of variable stars. Sometimes it equals in brightness stars of the second magnitude, sometimes it becomes completely invisible.[11] Its variations have been followed since the end of the Sixteenth Century, and it has been found that they are reproduced periodically every 331 days on the average. The study of these singular stars presents us with curious phenomena.

Lastly, the constellation of the Centaur is situated below Spica of the Virgin. The star θ, of the second magnitude, and the star ι, of the third, mark the head and the shoulder. This is the only part of this figure which rises above our horizon. The Centaur contains the nearest star to us (α) of the first magnitude, the distance of which is about twenty-five billions of miles. The feet of the Centaur touch the Southern Cross, formed of four stars of the second magnitude, always hidden below our horizon. It reigns in silence above the icy solitudes of the Southern Pole, where ships proceed only with difficulty. Further on, at the centre of the other hemisphere, is the southern celestial pole, which is not marked by any remarkable star.

It was from this region, Dante relates, that,[100] having visited hell, inclosed in the centre of the earth, he went to the Mountain of Purgatory, and from there to the Heights of Paradise. These beautiful dreams have disappeared in the sunshine of modern astronomy.

We will complete these descriptions by a little astronomical chronology, which is not without interest. From a careful examination of the most ancient historical sources of classical astronomy, the following is the order in which the constellations appear to have been noticed, formed, and named, beginning with the most ancient: Most Ancient Reference The Great Bear Job (ch. xxxviii. ver. 32) (Seventeenth Century before our era), Homer (Ninth Century). Orion Job (ch. ix. ver. 9), Homer, Hesiod. The Pleiades (the Hyades) Job (ch. xxxviii. ver. 31), Homer, Hesiod. Sirius and the Great Dog Hesiod mentions it. Homer calls Sirius the Star of Autumn. Aldebaran (Taurus) Homer, Hesiod. Boötes, Arcturus Job (ch. xxxviii. ver. 32), Homer, Hesiod. The Little Bear Thales (Seventh Century), Eudoxus, Aratus. Draco (the Dragon) Eudoxus (Fourth Century), Aratus (Third Century). The Man on his Knees, or Hercules Id. The Branch and Cerberus[12] Id. Corona Borealis Id. Ophiuchus or Serpentarius Id. The Scorpion Id. Virgo and Spica[101] Eudoxus (Fourth Century), Aratus (Third Century) Gemini (the Twins) Id. Procyon Id. Cancer (the Crab) Id. Leo (the Lion) Id. Auriga (the Charioteer) Id. Capella (the Goat, the Kids) Id. Cepheus Id. Cassiopeia Id. Andromeda Id. Pegasus (the Horse) Id. Aries (the Ram) Id. The Triangle Id. Pisces (the Fishes) Id. Perseus Id. Lyra Id. The Bird, or Cygnus (the Swan) Id. Aquila (the Eagle) Id. Aquarius Id. Capricornus Id. Sagittarius Id. Sagitta (the Arrow) Id. Delphinus (the Dolphin) Id. Lepus (the Hare) Id. Argo (the Ship) Id. Canobus (afterward written Canopus) Id. Eridanus Id. Cetus (the Whale) Id. Piscis Australis (the Southern Fish) Id. Corona Australis Id. The Altar Id. The Centaur Id. The Wolf (Lupus) Id. Hydra Id. Crater (the Cup) Id. Corvus (the Crow) Id. Libra (the Balance) Manetho (Third Century B. C.) Geminus (First Century) B. C.). The Hair of Berenice[13] [102] Callimachus, Eratosthenes (Third Century). Feet of the Centaur Hipparchus (First Century B. C.). Propus (η of Gemini) Hipparchus. The Manger and Donkeys Id. The Little Horse (Equuleus) Id. The Head of Medusa Id. Antinous[13] Under the Emperor Adrian (130 A. D.). The Peacock (Pavo) John Bayer, 1603. Toucan Id. Grus (the Crane) Id. Phœnix Id. Doradus Id. The Flying Fish Id. Hydrus Id. Chamæleon Id. The Bee (Musca) Id. The Bird of Paradise (Apus) Id. Triangulum Australis Id. The Indian (Indus) Id. The Giraffe (Camelopardus) Bartschius, 1624. The Fly (Musca) Id. The Unicorn (Monoceros) Id. Noah's Dove (Columba) Id. The Oak of Charles II Halley, 1679. The Southern Cross (already seen by the ancients) Augustine Royer, 1677. The Great and Little Cloud (Magellanic Clouds) Hevelius, 1690. The Fleur de Lys Id. The Greyhounds (Canes Venatici) Id. The Fox and Goose (Vulpecula et Anser) Id. The Lizard (Lacerta) Id. The Sextant of Urania (Sextans) Id. The Little Lion (Leo Minor)[103] Hevelius, 1690. The Lynx Id. The Shield of Sobieski Id. The Little Triangle Id. Mount Mænalus Flamsteed, 1725. The Heart of Charles II (α Canum Venaticorum) Id. The Sculptor's Workshop (Sculptor) Lacaille, 1752. The Chemical Furnace (Fornax) Id. The Clock (Horologium) Id. The Rhomboid Reticule (Reticulum) Id. The Engraver's Pen Id. The Painter's Easel (Pictor) Id. The Compass (Circinus) Id. The Air Pump (Antlia) Id. The Octant (Octans) Id. The Compass and Square Id. The Telescope (Telescopium) Id. The Microscope (Microscopium) Id. The Table Mountain (Mensa) Id. The Reindeer Lemonnier, 1774. The Solitaire (Indian Bird) Id. Le Messier Lalande, 1776. The Bull of Poniatowski Poczobut, 1877. The Honors of Frederick Bode, 1786. The Harp of the Georges Hell, 1789. The Telescope of Herschel Bode, 1787. The Electrical Machine Id, 1790. The Printer's Workshop Id. The Mural Quadrant Lalande, 1795. The Air Balloon Id., 1798. The Cat Id., 1799.

Such are the constellations, ancient and modern, venerable or recent, into which the celestial sphere has been divided. The ancient names are respectable[104] and respected, on account of their relations, known or unknown, with the origins of history and religion;

the new ones must be ephemeral. It is useful to know them, because several stars celebrated under different titles have for their principal designation their position in these asterisms; but what we should wish would be to see them disappear.[14]

Many other substitutions have, however, been attempted. I have in my library a splendid folio of the year 1661, containing twenty-nine engraved plates, illuminated in gold and silver, among which are two which represent the sky delivered from the pagans and peopled with Christians. Instead of divinities more or less virtuous, in place of animals of forms more or less fantastic, we behold the elect—apostles,[105] saints, popes, martyrs, sacred persons of the Old and New Testament—seated in the celestial vault, clothed in rich costumes of all colors, embroidered with gold, and carefully installed in the place of all the pagan heroes who for so many ages reigned in the sky.

The author of this metamorphosis was named Jules Schiller, and it was in the year 1627 that he introduced it, coupling his name with that of John Bayer. He began his dissertation by showing how the pagan constellations are opposed to Christian opinion and even to common-sense. He quoted the Fathers of the Church who expressly disapprove of them: Isodorus, who treats them as diabolical; Lactantius, who condemns the corruption of the human race; Augustine, who sends their heroes to hell, etc.

These constellations formed by chance, in the course of ages, without a fixed object; their inconvenient size, the uncertainty of their boundaries; the complicated designations, for which it was sometimes necessary to exhaust whole alphabets; the bad taste with which observers have introduced into the southern sky the frigid nomenclature of instruments used in science alongside mythological allegories—all these accumulated defects have often suggested plans of reform for the stellar divisions, and even the banishing of all configuration. But ancient customs are difficult to overcome, and it is very probable that, except the recently named groups, which we may now suppress, the venerable constellations will always reign.

[106]

Such are the provinces of the sky. But these provinces are of no intrinsic value; the important point for us is to make acquaintance with the inhabitants. FOOTNOTES:

[6] The French trillion is equivalent to the English billion, or a million times a million (1,000,000,000,000).—J. E. G.

[7] The Chinese had designated them all, it is true, at the same epoch, but their groups as well as their denominations are absolutely different from ours, and do not appear to have exercised any influence on the foundations of astronomical history. It was another world, other methods, other inspirations, as if Asia and Europe formed two distinct planets. A distinguished author, M. Schlegel, published in 1875 a Chinese Uranography, which is composed of 670 asterisms, and of which he believes he can trace back the origin to 17,000 years before our era. His argument is not convincing, and it seems to me that the origin of the astronomy of the Celestial Empire can not be very much anterior to the reign of the Emperor Hoang-Ti—that is to say, to the Twenty-seventh Century before our era—and would go back at furthest to the time of Fou-Hi that is to say, to the Twenty-ninth Century. It was about the same epoch—the Twenty-eighth Century before our era—that the Egyptians, observing Sirius, the early rising of which announced the inundation of the Nile, formed their canicular year of 365 days.

[8] More correctly, from 2.3 magnitude to 3.5 magnitude.—J. E. G.

[9] The author possesses in the Museum of the Observatory at Juvisy a Japanese executioner's sword, on the guard of which this constellation is engraved. Was it believed that the souls of executed criminals were sent there?

[10] See Astronomical Myths, based on Flammarion's History of the Heavens. By J. F. Blake. London, 1876.

[11] That is, to the naked eye; it never descends below the tenth magnitude, and always remains visible in a 3-inch telescope.—J. E. G.

[12] A constellation wrongly attributed by Arago and others to Hevelius. It is found on the sphere of Eudoxus.

[13] Constellations incorrectly attributed to Tycho Brahe. The first is given by Eratosthenes, the second dates from the Emperor Adrian.

[14] Especially those which are absolutely superfluous, and occupy places stolen from the ancient constellations, like the Heart of Charles II, the Fox and Goose, the Lizard, the Sextant, the Shield of Sobieski, Mount Mænalus, the Reindeer, the Solitaire, the Messier, the Bull of Poniatowski, the Honors of Frederick, the Harp, the Telescope, the Mural Circle, the Air Balloon, the Electrical Machine, the Printer's Workshop, and the Cat. I know, however, with reference to this last animal, that Lalande wrote: "I love cats! I

adore cats! I may be pardoned for having placed one in the sky after my sixty years of assiduous labors." But the illustrious astronomer had no necessity for this plea in order that his name should remain inscribed in letters of gold on the tablets of Urania. The Heart of Charles II is but the flattery of a courtier; the Shield of Sobieski, the Bull of Poniatowski, should fall from the sky; the Messier is but a play on words which makes the celestial flocks guarded by a pastor whose name is the same as that of the prolific hunter of comets, Messier. As for the Honors of Frederick, they usurp an unmerited place, for, in order to make room for them, Andromeda has been obliged to draw in her arm, which she had stretched out there for three thousand years. THE ARABIAN HEAVENS.—Ludwig Ideler

The majority of Arabic star-names mentioned by Kazwini owe their origin to the astronomy of the Greeks. For instance, to the latter belong El-dschediain, the two Kids (Hædi); El-ma'lef, the Manger; El-hhimârain, the two Asses; Kalb el-ased, the Lion's Heart; El-sumbela, the Ears; El-zubênâ, the two Claws. Others indicate the positions of the stars in the Greek constellations as Râs el-tinnîn, Dragon's Head; Râs el-hhauwâ, Head of the Snake Man; Râs el-dschêthi, Head of the Kneeling (Hercules); Dseneb el-dedschâdsche, the Hen's Tail (Swan's); Dseneb el-dschedi, Goat's Tail (Wild-goat); Dseneb Kaitos, Whale's Tail; Fom el-hhût, Jaw of the (southern) Fish; Ridschl el-dschebbâr, Giant's Foot (Orion), etc. Still others, such as Khebd el-ased, Dafîra el-ased, El-dsirâ el-mebsûta, and el-mekbûda, El-nethra, El-dschebha, El-zubra, Sâk el-ased, Adschaz el-ased, refer to the Arabic Lion, which is a caricature of the Greek one.

Now if we separate these and many similar expressions from the astronomical nomenclature of the Arabs, there remains a class of star-names that present sufficient internal evidence to show plainly that they are indigenous to Arabia. It is worth while taking the trouble to collect and compare them. We[107] shall in this way obtain a clearer idea of the sky that was altogether peculiar to this people.

In the first place, a large number of names of animals attracts our notice. In the vicinity of the North Pole, a shepherd (El-râï, Gamma in Cepheus), accompanied by his dog (Khelb el-râï, Zeta in Cepheus), is pasturing a herd of sheep (El-firk and El-agnâm, Alpha, Beta, Eta, and smaller stars in Cepheus), to which group also seem to belong two calves (El-ferkadain, Beta and Gamma in the Little Bear), a she-goat (El-anâk, Zeta in the Great Bear), a he-goat (El-tais in the Dragon), a young he-goat (El-dschedi, Alpha in the Little Bear), four mother-camels, a camel-foal, and a single camel pasturing by itself (El-awaîd, El-raba, and El-râfid, collectively on the head of the Dragon).

Various predatory animals are slinking around this herd, two Jackals (El-dsîbain, Zeta and Eta in the Dragon), which are specially stalking the camel-foal; a male-hyena (El-dsîch, Iota in the Dragon) and many other she-hyenas (El-dibâ, Beta, Gamma, Delta and Mu in Boötes), and other she-hyenas with their young (Aulâd el-dibâ, Theta, Iota, Kappa, Lambda, and others in the same figure).

In the neighborhood of the two jackals (two stars in the Dragon) bear the name of their claws (Adhfâr el-dsîb).

Another shepherd (El-râï, Alpha in Ophiuchus) pastures his sheep (El-agnâm, small stars in the region of Hercules's Club) on a mead (El-rauda), which is defended on the side of the above-mentioned hyenas by two hurdles (Nasak schâmi and Nasak[108] jemêni, rows of stars in Hercules and in the upper part of the Snake), and is open in the direction of the shepherd's two dogs (Khelb el-râï, Alpha in Hercules and Beta in Ophiuchus).

A third shepherd and a third herd are to be found further to the south in the Milky Way. The latter was represented as a river in which four animals (camels or sheep) are drinking, while four others (El-naâîm el-sâdira, Zeta, Sigma, Tau, and Phi, in the Archer), are going away from it after having quenched their thirst. Lambda in the Archer was regarded as their shepherd (Râï el-naâïm).

Yet another shepherd was signified by the star Beta in Orion (Rigel). He was called Râï el-dschauzâ, the shepherd in the Dschauzâ, or Nut-region, i. e., in the region of Orion, which is splendid with many conspicuous stars. The herd which he was given to pasture are probably the "Thirst-quenched Camels" (El-nihâl), which were regarded as being the stars Alpha, Beta, Gamma, and Delta, in the Hare in the vicinity of the Milky Way.

Besides these groups of animals, there are several others scattered over the heavens. The three pairs of stars standing close together at the feet of the Great Bear were likened to the footmarks of a gazelle. They were called the Gazelle's Springs, or Hoofs (Kafzât el-dhibâ or Dhufra el-gizlân). Naturally the animal itself was regarded as being in the neighborhood of its tracks. On the one hand, Omicron, Pi, Rho, Sigma, A and d, on the head of the Great Bear, and on the other, as it appears, the stars of the Little Lion were included under the name[109] Gazelle (El-dhibâ). The latter group also appears under the names the Gazelles and their Young (El-dhibâ w' aulâdhâ).

The five stars of the Virgin, Beta, Eta, Gamma, Delta, and Epsilon, were looked upon as so many yelping dogs (El-auwâ); Alpha and Beta in the Archer as a pair of birds peculiar to Arabia (El-suradain); Alpha (Fomalhaut) in the Southern Fish and Beta (Diphda) in the Whale as two Frogs (El-difda el-awel and El-difda el-thâni); four stars in the Great Dog and the Dove and as many Monkeys (El-kurûd), and the two bright stars of the latter constellation as a pair of Ravens (El-ag'riba).

All the creatures so far mentioned are familiar to the Arabs, the camel most of all. Just as their language is rich in words which refer to this useful animal, so also it plays the chief rôle in their astronomical nomenclature. We have already met with some camel-groups in the Arabian heavens. We find two more in the Bull and in the Crow. The brightest star in the Hyades has the name of "the Large Camel" (El-fenîk or El-fetîk), the others are called "the Small Camels" (El-kilâs or El-kalâjis). The four principal stars of the Crow were regarded as so many male-camels (El-adschmâl), analogous to the above-mentioned four female-camels in a similar figure at the head of the Dragon.

Just as frequently do we come across the ostrich in the Arabian heavens. The Southern Crown bears the name of the Ostrich Nest (Udha el-naâm), to which two pairs of ostriches (El-dhalîmain, Lambda and Mu in the Archer) appear to belong. A second[110] ostrich-nest was formed from a number of stars in the upper part of Eridanus. In the neighborhood are five hen-ostriches (El-naâmât, Zeta, Eta, Theta, Tau, and Upsilon) in the belly of the Whale, and somewhat further away are two male birds (El-dhalîm, Alpha in the Southern Fish and Alpha in the River). The latter have a number of young ostriches (El-rijâl stars in the Phœnix) between them. Ostrich eggs (El-baid), or their shells (El-kaid), are represented by small stars in the vicinity of the nest.

Besides the groups, we also find various isolated animals in the starry heavens of the Arabs. Among these is the Black Horse (El-dschaun, Epsilon in the Great Bear), perhaps belonging to the neighboring Governor (El-kâïd, Eta, in the same constellation); the beast of prey (Anâk el-ard, Gamma in Andromeda); the Male Camel (El-fahl), which was represented by Canopus and the Dog running in front of Sirius (El-khelb, Beta in Canis Major). This nomenclature, borrowed from the animal kingdom, to which must be added the Maidens (El-adsâra Omicron, Eta, Delta, and Epsilon in Canis Major); the Outrider and the Man-riding-behind (El-fawâris and El-ridf, Delta, Gamma, Epsilon, Zeta, and Alpha in the Swan); this nomenclature, I say, is peculiar in that only one star was always used to distinguish one animal.

The Arabs with so lively an imagination saw in the skies sheep, camels, ostriches, but without being led to it by the resemblance of the contour of the entire star group, as was the case of the designers of[111] the Greek heavens. They therefore had no animal figures proper, but only animal names, such as the She-goat, the two He-goats, and the two Asses of the Greeks. On two occasions, however, it happened that more than one star was given to one animal. When the eight stars of the Archer, which were represented under the figure of only four animals at pasture going to and returning from drinking, were regarded by some as two ostriches, this does not seem to be an exception to the rule, but a misunderstanding instead, caused by the resemblance of two words (Naâïm and Naâm). The case is probably the same with the four stars, Delta, Pi, Rho, and Epsilon, in the Dragon which are called the He-goat by a very late Arab astronomer; for a star-name given by the lexicographer, Firuzabadi, would argue that analogy held true here also.

The two unmistakable cases to which I refer are those of the falling and flying Eagle (El-nesr el-wâki and El-nesr el-tâïr), the former of which was made up of three stars in the form of an equilateral triangle, and the latter of three standing in a straight line (Alpha, Epsilon, and Zeta of the Lyre, Alpha, Beta and Gamma of the Greek Eagle).

We need not take into consideration in this connection either the Arabic Lion or the complete Horse, since most probably both owe their origin to false interpretations of later grammarians.

It is quite different with a second class of Arabic star-names which signify inanimate objects. These have to do with real forms throughout, which, however, for the most part consist of only a few stars[112] after the manner of the Greek Arrow and Triangle. To these belong El-chibâ, the tent of the Arab nomads resting on three or four supports. One of these was represented by three stars of the Charioteer (Lambda, Mu, and Sigma), and another by the four chief stars of the Crow.

El-athâfi, the three stones which the nomadic Arab placed under his pot or kettle in the form of an equilateral triangle to form the hearth. Every triad of stars standing in a similar figure might be called an Athâfi; for instance, Delta, Epsilon, and Rho in the Ram, and the three on the head of Orion, which were actually likened to one of these. In just so many words, however, the only stars that occur under this name are Alpha, Epsilon, and Zeta in the Lyre, and Sigma, Tau, and Upsilon in the Dragon.

El-kidr, the Pot, a ring of stars in the vicinity of the last Athâfi, which was formed from a number of small stars of Cepheus and the Swan.

El-midschdah, the wooden twirling-stick (spit). A kitchen utensil of similar triangular form was represented by the Hyades. The name in course of time came to be restricted to the chief star of this group.

El-fekka, the sounding plate with the broken rim, or Kas'a el-masâkhîm, the Beggar's-dish. This name was given to the stars of the Northern Crown, which stand in a circle open toward the northeast.

El-mîzân, the Scale-beam, an appropriate name for three stars in a straight line. The ancient Arabs used it for Theta, Eta, and Delta in the Eagle; the modern ones use it to distinguish the three stars on[113] the Belt and the three on the Sword of Orion, the former of which, on account of their equal distance from each other, are called the true scale-beam, and the latter the false one, on account of the unequal intervals.

El-dsirâ, the Ell, a term which may fitly be applied to every pair of conspicuous stars standing a certain distance from one another. It was used for the two pairs of stars on the head of the Twins and in the Little Dog.

El-ma'lef, the Manger—the name of the stars of the Cup which stand in a circular form. The more familiar Manger in the Crab belongs to the Greek Heavens.

El-kubba, the Traveling-tent, drawn by camels of the Arab's female apartment. This name was given by some to the stars of the Southern Crown, while others, as has already been remarked, regard it as an Ostrich Nest.

El-zaurak, the Boat, was represented by the chief stars of the Phœnix. El-delv, the Well-Bucket, represented by the Square of Pegasus, occurred more frequently than any other, as is shown by the star-names relating to it—El-ferg, El-arkûwa, El-khereb, and Elnaâïm. Elna'sch, the Bier, was applied to the well-known quadrangle in the Great and Little Bear. The term particularly signifies the death-bier, and taken in this sense each of the two biers is accompanied by three mourning women—Benât—biers and mourners combined are called Benât na'sch, literally Daughters of the Bier, i. e., belonging to the Bier.

El-salîb, the Cross: one of these was referred to[114] under the four stars on the head of the Dragon, which others regarded as four mother camels. A second was found in the stars of the Dolphin.

El-serîr, El-khursi, El-arsch, various kinds of Thrones. One, named Serîr benât na'sch, was represented by seven stars standing in the form of a bow on the head of the Great Bear, which were also called El-hhûd, the Pond. Two other thrones under the names Khursi, or Arsch el-dschauzâ, were distinguished under four stars of Eridanus, and four in the Hare, and yet another, named Arsch el-simâkh el-a'zal, in the stars of the Crow.

El-nidâm and El-nedm, every set of things arranged in a row, especially the Pearl Necklace, which was the name given to the four stars 1, 2, 3, 4, and Phi of the Whale standing in a straight line, and the three on Orion's Belt. Synonymous with this, among words taken in their common acceptation is El-nasak, a name used for two rows of stars in the upper part of the Snake and Hercules, which also has a picturesqueness about it, since the two rows were regarded as hurdles around the meadow on which the above-mentioned shepherd pastures his flock.

El-fikrat, El-fekâr, and El-kelâda, the Brooch: the first of these appears as the name of the stars on the vertebra of the Scorpion's tail; the second, for Orion's Belt; the third, for stars of the Archer. El-dschauzâ, the Nuts, and El-lekat, the Golden-grains or Spangles. The former name was used for the stars of Orion and the neighboring Twins collectively, the latter merely for those on Orion's Sword.[115] Finally, to this class belongs El-khaf el-chadîb and El-khaf el-dschedsmâ, the Dyed and the Mutilated Hand, which figures were represented by the five chief stars of Cassiopeia and the five better known on the head of the Whale. Several of these figures, as we have seen, appear at more than one place in the sky. Hence arose, for astronomers at least, the necessity for distinguishing epithets. Thus the Cross on the head of the Dragon was called "the falling," the Tent in the Crow "the southern," one of the Biers "the smaller," the other, "the greater"; one of the thrones in the vicinity of Orion, "the front"; the other, "the back."

When these distinctions are wanting, as in the case of the Athâfis, it is probably because the astronomers only made use of the one in the Dragon. Ulug Bekh does not name the other in the Lyre; Kazwini also states that it only occurred in the speech of the common people.

There is still a third and very numerous class of genuine Arabic star-names, which, borrowed neither from animate nor inanimate objects, are consequently names that do not represent any figures. They owe their origin to many circumstances, the majority of which are lost to us. I will content myself with mentioning only a few of them whose origin is not shrouded in doubt.

The small star over the middle of the Great Bear's tail is called El-suhâ, the Forgotten, the Lost, because it is only noticeable to a sharp eye; also El-saidak, the Touchstone (test-stone), because by it the eyesight was tested; Arcturus, Hâris el-semâ, the[116] Warder of the Heavens, because it is never entirely lost in the rays of the sun; Capella, Rakîb el-thorejâ, the Watchman of the Pleiades, because it rises at the same time as they do; Alpha (Aldebaran), in the Bull, Hhâdi el-nedschm, the Driver of the Seven Stars; also El-tâbi and El-debarân, the Follower, because it rises immediately after that constellation; Beta (Denebola) in the Lion, El-serfa, the Breaker-up (Upsetter), because at its rising and setting in the morning twilight the hot and cold weather change; Alpha (Ras Alhague) in the Watersnake; El-ferd, the Isolated, because it is situated in a starless region, etc. Besides this, among this class we must include the Su'ûd, or fortunate stars, four of which are in Pegasus, two in the Wild Goat, and four in the Waterman.

It will already have been noticed that in this nomenclature single stars frequently appear under several names. Thus the stars of the Crow are sometimes called El-adschmâl, the Camels; sometimes El-chibâ el-jemêni, the Southern Tent; sometimes Arsch el-simâkh el-a'zal, the figure of the throne in the neighborhood of Spica—three quite different names which express so many various notions and have also so many separate authors.

Who were the originators of this nomenclature as a whole?

The Arabs, and particularly the nomad Arabs. To prove this we have only to cast a glance at the names in the first two classes.

The inhabitants of the northern part of the Arabian peninsula, the so-called "desert" and "stony"[117] Arabia, for the most part, lead a nomadic kind of life.

The country is a treeless and waterless plain covered with naked rocks and sand-drifted hills, on which lie scattered single oases watered by springs and glorified with a luxuriant vegetation. On these the Arabs camp with their herds, and do not leave them until the provender is consumed, or until more powerful tribes force them to depart. They call themselves Bedâvi (Bedouins), that is, Scenitæ, Nomads, as they were called by the Greeks. These nomads, cut off from all intercourse with the world around them, who have never been subjugated by a foreign power, have preserved their character and their customs unchanged for several thousand years. Their most important occupation is cattle-breeding. Besides this, they follow the chase, or war upon their enemies, regarding as such all those not belonging to their race or who are not under their protection. They dwell in tents. Several families are under a Schech and several Schechs generally under an Emîr, who rules over the whole tribe.
